FRUCTUS CANNABIS, Hempseed.—Hempseed is about $\frac{1}{8}$ to $\frac{1}{4}$ of an inch in length, subglobular, somewhat compressed, and possessing a marginal keel, whitish in color. The testa is brownish or olive-gray, smooth, shining, brittle, and marked with veins. The inclosed greenish seed is oily, with a sweetish, oleaginous taste, and but a faint odor.

Chemical Composition.—The leaves of cannabis contain chlorophyll, coloring matter, extractive, a volatile oil, a green, resinous body, gummy extractive, a bitter body, albumen, lignin, sugar, and salts, as potassium nitrate, silica, phosphates, and other salts. The chemistry of the active constituents is not yet well determined. Not since T. & H. Smith (1846), declared that the soporific, calmative,

Fig. 54.

Cannabis sativa.

and other properties, resided in the resin *cannabin*, have any very material advances been made. Personne (1857) thought the activity of the drug depended upon its volatile oil, the vapor of which is stupefying. He succeeded in separating it into two parts—*cannabene* ($C_{15}H_{20}$), a fluid, and *cannabene hydride* ($C_{15}H_{22}$), a crystallizable solid. The oil rectified (over sodium), is miscible with alcohol, boils at 256° to 258° C. (492.8° to 496.4° F.), and has a density at 0° C. (32° F.), of 0.9292. Bromine energetically attacks it (Valente, 1881).

The *cannabin* of T. & H. Smith is the alcoholic or resinous extract employed in medicine; it is prepared from the dried flowers and incipient fruit, with the smaller branches of the plant (*gunjah*). This extract is prepared according to the directions of Messrs. Smith, as follows: "Digest bruised *gunjah* in successive quantities of warm water till the expressed water comes away colorless; and again for two days, at a moderate heat in a solution of carbonate of sodium, in the proportion of 1 part of the salt to 2 of *gunjah*. Coloring matter, chlorophyll, and inert concrete oil being thus removed, express and wash the residuum, dry it, and exhaust it by percolation with rectified spirit. Agitate with the tincture, milk of lime containing an ounce of lime for every pound of *gunjah*, and after filtration, throw down the excess of lime by a little sulphuric acid. Agitate with the filtered liquor a little animal charcoal, which is afterward to be removed by filtration. Distill off most of the spirit, add to the residual tincture twice its weight of water in a porcelain basin, and let the remaining spirit evaporate gradually. Lastly, wash the resin with fresh water till it comes away neither acid nor bitter, and dry the resin in thin layers." This resinous extract contains the taste and odor of *gunjah*, and its activity is not impaired when exposed in air for 8 hours to a temperature of 82.2° C. (180° F.). One hundred pounds of dry *gunjah* yield about 6 or 7 pounds of this extract (P). It has a dark, dull-green color, a peculiar narcotic, somewhat fragrant odor, and a hot, somewhat bitter, and acrid taste. It is mostly soluble in alcohol, chloroform, ether, oil of turpentine, olive oil, and partially in benzol; its terebinthine solution deposits minute scaly crystals on standing. It burns without leaving a residue. When water is added to its solution in alcohol, a white precipitate falls. It may be distinguished from the extract of common hemp by the following tests: Resinous extract of Indian hemp only partially dissolves in liquor potassæ, while that of common hemp dissolves readily; nitric acid, sp. gr. 1.38, converts the former, with red fumes and rapid reaction, into an orange-red resinoid substance, amounting to nearly the same quantity as the resin under treatment, while the extract of common hemp gives but a small amount of resinoid (Prof. W. Procter).

In the year 1876, Preobraschensky obtained a volatile alkaloid which he believed to be nicotine, but Dragendorff suggests the possible admixture of tobacco, as the latter and hemp are frequently smoked together; at least others have not succeeded in isolating nicotine from hemp. By using the methods for extracting nicotine, Siebold and Bradbury (1881), extracted a very minute quantity of *cannabinine*, a varnish-like mass. In 1883, Matthew Hay arrived at the conclusion that several alkaloids are contained in the plant—one of which, in crystalline form and possessing tetanic properties, he succeeded in isolating in minute quantity and named *tetano-cannabinine*. Jahns (1889), however, claims this body to be identical with choline. In 1891, H. T. Smith extracted a varnish-like alkaloid, possessing the odor of coniine; of this he formed a sulphate which crystallized from alcohol. More recently (1895), F. Marino-Zuco, and G. Vignolo (*Gazetta Chimica Italiana*, 1895, part I, pp. 262-8), have attempted to determine definitely the constituents of the drug. They succeeded in obtaining from the drug by means of water acidulated with sulphuric acid, an alkaloidal base, the hydrochloride of which formed a deliquescent, crystalline mass, which to the heart is a powerful depressant. As vegetable acids destroy or render practically inert the action of *Cannabis indica* (Polli), it is not readily accepted that a stronger acid should be expected to extract the active principle or principles (*Pharm. Jour.*, 1895). The *Pharmaceutical Journal*, 1895, remarks: "The chemistry of this remarkable and powerful drug still remains to be elucidated, therefore, and the active principles to which its complex action is due yet await isolation. It may, perhaps, serve as a hint to investigators, to recall a statement which appears in Schlimmer's (Persian) *Pharmacopœia* (p. 102), from which it appears that the der-

vishes make an extremely somniferous preparation by boiling the tops of Indian hemp in fresh butter or oil of almonds. 'Of this a sufficiently minute quantity introduced into an ordinary culinary preparation will cause an entire family to sleep for 24 or 72 hours, without the taste of cannabis being detected.' Assuming the intoxicant action and the odor of Indian hemp to be due to a volatile constituent likely to be driven off by the boiling process, the use of the oil as a solvent might serve to separate the most important active principle, and another might be separated by distillation. Hitherto most of the processes adopted appear to have yielded products incapable of causing the characteristic action of the drug." Gastinel's *hashiscin* is an alcoholic extract of gunjah, from which the water-soluble principles are excluded. Bombelan's *pure cannabin*, Merck's *cannabin tannate*, or Kobert's *cannabindine*, are not thought to be the active principle proper (*Pharm. Jour.*, 1895).

Action, Medical Uses, and Dosage.—Administered to healthy persons in large doses, cannabis creates more or less disturbance in the digestive tract, affects the nervous system with convulsive movements and sudden shocks, causes congestion of the brain, confused ideas, exalted imagination with frequently changing pictures, torpor, and sleep; the cerebral symptoms being more constant, while the others vary to a great extent, sometimes nothing occurring but a few confused ideas followed by sleep. The long-continued use of this article induces injected eyes and bloating of the face, prostration, dropsy, sudden attacks of dangerous mania, and occasionally catalepsy and imbecility, followed by a marasmic state, ending in death. Death has not been known to result directly from the effects of cannabis, except when continually used until marasmus is induced, when death may occur from the latter condition. The symptoms of acute poisoning vary greatly, probably owing to the uncertain character of the drug employed. Collapse, unconsciousness, stupor, catalepsy, extreme debility, irresponsive pupils, cold, clammy skin, spasms and convulsions are among its toxic effects. A marked feature is the anæsthesia produced, and it is asserted that the Chinese formerly performed surgical operations under its use. The effects from large doses are best combatted by vegetable acids, especially lemon juice, coffee, emetics, cold applications and leeches to the temples. Probably strychnine and faradization of the respiratory muscles are the most effective means. By some coffee is said to increase its effects. Indian hemp is considered anodyne, hypnotic, antispasmodic, and phrenic, producing sleep even where morphine has failed, and without impairing the appetite, repressing the secretions, or causing constipation like opium and its preparations. It frequently allays pain, and has been found of great benefit in *hysteria*, *chorea*, and other *nervous affections*. Its effects upon the system vary under different conditions, thus: It lessens pain, checks spasmodic action, improves the appetite, causes sleep, exhilaration of spirits, and, in increased doses, inebriation, with phantasms, catalepsy, illusory delirium, and strong aphrodisia. Its continued use, however, lessens the venereal appetite and power. It occasions dilatation of the pupils and prevents normal perception more strongly than any other agent. A peculiarity observed in those who take cannabis is the strong and voracious appetite induced. Medicinally, in small doses, its effects are less intense than those of opium, and the excretions are not so much suppressed by it; it does not disturb digestion, rather increases the appetite, seldom induces sickness of the stomach, never causes congestion, and disturbs the expectoration far less than opium, also effects the nervous system much less, and produces a more natural sleep without interfering with the actions of the internal organs. Cannabis is one of the most important of our remedies, but, like our best agents, it must not be used indiscriminately, but its cases should be specifically selected. The great indication for cannabis (the keynote) is *marked nervous depression*. With this indication present it will fulfil a multitude of uses. Specifically selected it has been efficient in *delirium tremens*, *wakefulness in fevers*, *neuralgia*, *gout*, *rheumatism*, *infantile convulsions*, *low mental conditions*, *insanity*, etc., and in *inflammatory conditions* in cases where opium disagrees, and is often preferable to opium. *Acute mania* and *dementia*, *epilepsy*, *hysterical catalepsy*, *cerebral softening* (with potassium bromide), *anemia of the cerebral cortex*, *paralysis agitans* and *senile tremors*, *traumatic* or *idiopathic tetanus*, and *irritable reflexes*, are among the nervous disorders in which it exerts a positively beneficial and soothing action, when depression is the guide

to its selection. In mental disturbances the guides to its use are mental oppression, a dull, drowsy, or stupid countenance (a dreamy condition), with dizziness and violent throbbings in the head, and a morbid fear of becoming insane. The patient sometimes has an "exaggerated idea of time and space" (Webster). The drug is a useful hypnotic for the insane. As a remedy for pain, it ranks among the first; the more spasmodic the pain the better it acts. The neuralgic pains of depression are those most quickly relieved. It should be administered in painful states of the stomach, as *gastric neuralgia*, *nervous gastralgia*, in *gastric ulcers*, where opium is inadmissible, and in pain due to indigestion. The pains attending *lientery*, *after-pains*, the passage of *renal* and *hepatic calculi*, *gout*, *neuralgia of the uterus*, *cancer*, *locomotor ataxia*, are all met by it, and, added to purgatives, it mitigates their griping effects. It relieves the itching of *cutaneous disorders*, particularly that of *senile pruritus* and *eczematous affections*. *Migraine*, *nervous headache*, *facial*, and other *neuralgias*, whether due to catamenial wrongs or attending the menopause, as well as those depending upon fatigue, are relieved when nervous depression is the most marked symptom. *Head-pains*, due to *tumors*, have been asserted to yield to cannabis. The pains of *chronic rheumatism*, *sciatica*, *spinal meningitis*, *dysmenorrhœa*, *endometritis*, *subinvolution*, and the vague pains of *amenorrhœa*, with depression, call for cannabis. Owing to a special action upon the reproductive apparatus, it is accredited with averting *threatened abortion*. It is a prominent remedy for certain spasmodic conditions and especially in the *chorœic states* of weak women and children. It mitigates *whooping-cough* and other *convulsive coughs*; alleviates *palpitation of the heart*, with stitching pain in the part; quiets *hysterical manifestations*, and allays the distressing symptoms of *spasmodic asthma*, and *periodic hyperæsthetic rhinitis*. It is a valuable remedy in *senile catarrh*, with harassing cough and profuse mucous expectoration, and, both internally and by inhalation, it has afforded relief in the painful *cough of consumptives*.

Cannabis is said in many cases to increase the strength of the uterine contractions during parturition, in atonic conditions, without the unpleasant consequences of ergot, and for which purpose it should be used in the form of tincture (see below), 30 drops, or specific cannabis, 10 drops, in sweetened water or mucilage, as often as required. In *menorrhagia*, the tincture in doses of 5 or 10 drops, 3 or 4 times a day, has checked the discharge in 24 or 48 hours.

The greatest reputation of cannabis has been acquired from its prompt results in certain disorders of the genito-urinary tract. In fact, its second great keynote or indication is *irritation of the genito-urinary tract*, and the indication is even of more value when associated with general nervous depression.

It is, therefore, useful in *gonorrhœa*, *chronic irritation of the bladder*, in *chronic cystitis*, with painful micturition, and in *painful urinary affections* generally. It makes no difference whether a *urethritis* be specific or not, or whether it is acute or chronic, the irritation is a sufficient guide to the selection of cannabis. Use it in *gonorrhœa* to relieve the ardor urinae, and to prevent urethral spasm and avert chordee, and in *gleet*, to relieve the irritation and discharge; employ it also in *spasm of the vesical sphincter*, in *dysuria* and in *strangury*, when spasmodic. Burning and scalding in passing urine, with frequent desire to micturate, are always relieved by cannabis. The following is said to be a certain cure for *gonorrhœa*: Take, while in blossom, equal parts of the tops of the male and female hemp (*Cannabis sativa*), bruise them in a mortar, and express the juice; to this add an equal portion of alcohol. Dose, from 1 to 3 drops every 2 or 3 hours. It should be remembered that the American hemp has the same properties as the Indian hemp, but is a much feebler product—the difference, therefore, not being, as some have indicated, in action, but merely in degree. Cannabis has been recommended in *diabetes* and *hematuria*, and in *Bright's disease*, with painful voiding of bloody urine, it is strongly endorsed. By its control over the mental functions, it controls lascivious thoughts, dreams and desires, and is, therefore, of some value in *nocturnal seminal emissions*. Probably its control over urethral irritation contributes to its value here. In this manner *impotence* is said to have been cured by it. Cannabis has some reputation as a remedy for *chronic alcoholism*, and for the cure of the *opium habit*.

Externally, the resin may be applied endermically or in embrocation with oils, ointments, chloroform, etc., in *inflammatory and neuralgic affections*. It may

also be used in injections. The green plant collected in the spring, and 2 or 3 twigs placed in or between beds, will, it is asserted, certainly and effectually cause bedbugs to remove from the room in which they are used. Hemp seed, in infusion, has been found very useful in *after-pains*, and in the bearing-down sensation accompanying *prolapseus uteri*. A combination of cannabis, collodion, and salicylic acid has been used to destroy corns, the extract of the hemp acting as an anodyne.

A tincture may be made by dissolving 24 grains of the resinous extract in a fluid ounce of rectified spirit; for ordinary purposes, its dose is from 10 to 80 drops. The extract varies in strength, which will require a variation in the doses. When well prepared, the dose is from $\frac{1}{2}$ grain to 1 grain; but this may vary from 1 grain to 20 grains, depending entirely on the quality of the article. The English extract is a good preparation, and of all extracts, the smaller dose should first be employed. The tannate of cannabine, in doses of 5 to 15 grains, is said to be an efficient hypnotic, though many declare it inefficient for this purpose. The best preparation is the specific cannabis, which may be given in doses of a fraction of a drop to 10 drops. The ordinary prescription for its specific effects is: R Specific cannabis, grt. v to xxx; aqua, flziv. Mix. Dose, a teaspoonful every $\frac{1}{2}$ to 2 or 3 hours.

Specific Indications and Uses.—Great nervous depression; irritation of the genito-urinary tract; painful micturition, with tenesmus; ardor urinæ, scalding, burning, frequent micturition; low mental conditions; wakefulness; insomnia, with unpleasant dreams during momentary sleep; spasmodic and painful conditions, with nervous depression; mental illusions; menstrual headache; palpitation of the heart, with sharp stitching pains in the heart; hallucinations; cerebral anemia, from spasm of cerebral vessels.

CANTHARIS (U. S. P.)—CANTHARIDES.

"*Cantharis vesicatoria*, De Geer"—(U. S. P.). (*Lytta vesicatoria*, Fabricius; *Meloë vesicatorius*, Linné).

Class: Insecta. Order: Coleoptera.

COMMON NAME AND SYNONYM: *Spanish flies*; *Muscæ Hispanicæ*.

Source, History, and Description.—There are a number of insects inhabiting various sections of the world which possess acrid properties, and which, when applied to the skin, produce vesication; the most common in use are those under present consideration, Spanish flies, or cantharides, the *Cantharis vesicatoria* of Latrielle, *Meloë vesicatorius* of Linnæus, or *Lytta vesicatoria* and *Cantharis officinalis* of other naturalists. At what period they were introduced into the practice of medicine is a matter of uncertainty. The beetle, called Spanish fly, is a native of Europe, where it is collected principally in south Russia and Hungary; also in Italy and Spain. It is imported into this country from Messina and St. Petersburg. Those from Russia are the best, and may be known by being larger than the French or English varieties and more copper-colored.

General Characters.—Antennæ elongate, simple, filiform; maxillary palpi with terminal joint somewhat ovate; head large, heart-shaped; thorax small, rather quadrate, narrower than the elytra, which are as long as the abdomen, soft, linear, the apex slightly gaping; wings 2, ample (J. F. Stephens). *Cantharis vesicatoria*, De Geer, the Spanish fly, is of an elongated, almost cylindrical form, from 6 to 11 lines in length, and 1 or 2 lines in breadth. This insect may be distinguished from other analogous ones, by presenting 2 shining-green wing covers, which cover 2 membranous wings, ample, thin, veined, transparent, pale-brown; black, jointed antennæ, and a longitudinal furrow along the head and chest. Their smell is strong, virose, very disagreeable, and compared to that of mice; their taste is acrid, burning, and urinous (Ed.). It is of a grass or copper-green color, with numerous whitish-gray hairs on its body and thorax. The head is large, subcordate, the eyes lateral and dark-brown; the thorax not larger than the head and narrowed at the base; the elytra or wing-covers are from 4 to 6 lines long, and from $\frac{3}{4}$ to 1 $\frac{1}{2}$ line broad; the costa are slightly margined; the wings 2, with tips folded; the legs are stout, from 4 to 6 lines long, the hinder ones longest. The abdomen is soft, and broadest in the female. In the female, near the anus, are

2 articulated caudal appendages (P.). The *U. S. P.* thus describes cantharis: "About 25 Mm. (1 inch) long and 6 Mm. ($\frac{1}{4}$ inch) broad; flattish-cylindrical, with filiform antennae, black in the upper part, and with long wing cases and ample, membranous, transparent, brownish wings; elsewhere of a shining, coppery-green color. The powder is grayish-brown, and contains green, shining particles. Odor strong and disagreeable; taste slight, afterwards acrid. Cantharides should be thoroughly dried at a temperature not exceeding 40° C. (104° F.), and kept in well-closed vessels."

The Spanish fly inhabits the earth in the form of a larva, and comes forth in the state of a fly in the month of May. It infests various trees, as the elder, rose, plum, willow, poplar, and elm, but more especially the privet, lilac, ash, and honeysuckle. They are caught during the month of May, either early in the morning or late at night, when the cold renders them less active; to undertake their removal in the daytime would be a serious measure. Those who gather them cover their faces and guard their hands with gloves, then shake them from the bushes over sheets, and kill them immediately by immersion in vinegar, or by exposure to the vapor of vinegar, spirit, or oil of turpentine. Hager recommends the use of carbon disulphide for this purpose; 7 Cm. to each liter of cantharides in bulk. Thus they are left in a closed vessel for one day. They are then quickly dried in the sun, or with artificial heat which, as stated above, should never rise above 40° C. (104° F.). They are best dried by placing them over caustic lime at a temperature of from 25° to 30° C. (77° to 86° F.).

In the dried state the flies may be known by the preceding descriptions as to color, form, odor, and taste; they are easily reduced to a dirty, grayish-brown powder, dotted with numerous brilliant green points. These points consist of the elytra, head, etc., and do not readily decompose, even when mixed with decaying animal matters. Orfila has recognized these particles in a body nine months after interment. The vesicating property of the flies may be preserved for many years, if they are kept from moisture in well-stoppered bottles, powdering them only as required. If purchased in powder they may have lost their activity, or suffered from adulteration with euphorbium, capsicum, or with some other insects. To preserve them from insects, various means have been advised, as the introduction of a few lumps of camphor into the vessel containing them, or the addition of carbonate of ammonium, or a few drops of strong acetic acid. Chloroform vapor is said to excel them all. Exposing them for $\frac{1}{2}$ hour in glass bottles, to the heat of boiling water, destroys the insects and eggs, without impairing the virtues of the flies; of course they must not be allowed to come in contact with the water. The properties of the fly are much diminished by the insects which feed upon them.

Chemical Composition.—Cantharides powder yields its active properties to boiling water, acetic acid, alcohol, proof-spirit, ether, the fixed and volatile oils. The active principle is a white, crystalline substance termed *cantharidin*. It is in small, white, pearly prisms, or scaly crystals, which are neutral, practically insoluble in water and cold alcohol, but soluble in ether, benzol, chloroform, acetone (E. Dietrich), alkaline solutions, acetic acid, acetic ether, the oils, wood alcohol, and in boiling alcohol, which deposits it upon cooling, and is insoluble in carbon disulphide; it fuses at 98.8° C. (210° F.), volatilizes at a higher heat without decomposition, and evaporates slowly at ordinary temperatures. It is said to exist principally in the trunk and soft parts of the body, and may be obtained by exhausting powdered cantharides with cold rectified spirit by percolation, concentrating the tincture till most of the alcohol is expelled, and allowing the residue to rest for a long time until crystals form. It may be freed from impurities by elutriation with a little cold rectified spirit, which scarcely acts on crystallized cantharidin; and it may be obtained quite pure by redissolving them in boiling rectified spirit, adding animal charcoal, and recrystallizing them by rest and cooling. Ether is, however, preferred to alcohol in preparing these crystals, as it dissolves less of the green oil, which is very difficult to separate. E. Dietrich (in 1880), has obtained cantharidin in brilliant white crystals by dialysis. The yield was above 0.28 per cent. The composition of cantharidin is represented by $C_{10}H_{12}O_4$, or according to Krafft (1877), $C_{10}H_{14}O_4$. It may likewise be prepared by macerating, at three consecutive times, very finely bruised cantharides, for

24 hours, in a sufficient quantity of chloroform, and then removing this by distillation. The green, thick residue is then treated by carbon disulphide, which dissolves the fatty matter. Throw the whole on a filter, which retains the crystallized cantharidin, which may be purified by several solutions in chloroform (W. Procter, A. Fumouze, M. Mortreux). Baudin (*Am. Jour. Pharm.*, 1889), found 1 per cent total cantharidin, of which 0.72 per cent is abstracted by pure chloroform and 0.3 per cent by chloroform acidulated with 2 per cent of hydrochloric acid. M. Fumouze does not consider cantharidin to be the active vesicating principle of the flies; some cantharides 8 or 10 years old, from which he could obtain no appreciable amount of cantharidin, nevertheless, produced prompt vesication when applied to the skin.

Cantharides contain, besides cantharidin, a green oil, soluble in alcohol, black matter, soluble in water, insoluble in alcohol; a fatty matter, insoluble in alcohol, a yellow viscid substance soluble in water and alcohol, yellow matter soluble in ether and alcohol, free acetic and uric acids, phosphates of calcium and magnesium, etc. (P.). Formic acid is said to be present also (E. Dietrich, 1883). This acid is the best solvent for cantharidin, and this fact may explain why decoctions and alcoholic preparations of cantharides are active, as cantharidin, which is generally believed (against Fumouze) to be the vesicating agent, is practically undissolved by water or by cold alcohol. Others explain the solvency of cantharidin in decoction and tincture as being due to its being combined in the beetle, with the yellow matter, which is dissolved by both alcohol and water. The best menstruum (for ordinary use), for cantharides, is chloroform, or ether, which dissolves only the active constituents. Cantharides, in powder or tincture, is sometimes used criminally for aphrodisiac purposes, and is administered to the female victim in coffee, chocolate, brandy-punch, wine, porter, ale, etc. If any particle of the flies is present, the microscope will detect it; otherwise, the only resource left is to ascertain whether cantharidin is present in the suspected liquid. The best test in such a case is to demonstrate its vesicating power. According to C. B. C. Tichborne, Esq., this may be accomplished by the following process: To $\frac{1}{4}$ pint of the suspected fluid add 1 fluid ounce of chloroform (or in like proportion with smaller quantities), and allow it to stand 24 hours, frequently agitating; then allow the mixture to subside, carefully separate the chloroform with a funnel, and filter it through bibulous paper; evaporate the chloroformic solution, spontaneously, in a watch glass, to dryness. A small pellet of lint about half the size of a pea, made loose by teasing out the fibers, and moistened with a drop of olive oil, is gently rubbed over the surface of the watch glass so as to mop off the whole of the film of extractive matter, then applied upon the arm, covered with a piece of goldbeater's skin, and allowed to remain on the arm for 3 or 4 hours. Then remove the lint, wipe off the surface of the arm upon which it had been applied, with chloroform, and if the suspected fluid contained cantharides, rubefaction and vesication will be observed. By this process, 1 grain of cantharides, equal to about $\frac{1}{12}$ of a grain of cantharidin, may be detected in solution.

Cantharidin ($C_{10}H_{12}O_4$), is an anhydride of *cantharidic acid* ($C_{10}H_{14}O_5$), which forms a line of salts called cantharidates. When these salts are warmed with an acid, cantharidin is regenerated as an insoluble compound. Cantharidin, by prolonged heating with hydriodic acid, is converted into *cantharic acid* ($C_{10}H_{12}O_4$), a crystalline monobasic acid to which the double formula ($C_{10}H_{14}O_5$), was assigned by Kraft, its discoverer. A solution of this substance in glycerin does not vesicate. All these compounds are derivatives of the hydrocarbon $C_6H_4(CH_3)_2$, which is a hydrogen addition product of *ortho-xylene* or *ortho-dimethyl benzene*.

Action, Medical Uses, and Dosage.—In large doses cantharis is narcotic and irritant; in medicinal doses, stimulant and diuretic. The earliest symptom produced by the smaller dose is irritation of the genito-urinary tract, and if continued, or the dose be larger, strangury with burning pain, and voiding of bloody and albuminous urine results. In large doses, its use is dangerous, being attended often by constriction and difficulty in swallowing, and by violent inflammation of the alimentary canal and urinary organs, strangury, irritation of the sexual organs, and in the female, abortion; also, redness of face, heat, hurried respiration, quick, small pulse, headache, delirium, tremors, tetanic convulsions, and coma. Burning pain is felt in the stomach, and nausea and vomiting follow, with

abdominal tenderness, violent griping and purging, the stools being bloody or fibrinous. Ptyalism is excessive, there is a cadaverous odor to the breath, and burning thirst is prominent. Upon the genito-urinary tract its effects are very severe, causing severe burning pain in the kidneys and bladder, with first an increased, then a diminished, flow of urine, with constant urging to urinate, and the act attended with great difficulty, the water passing drop by drop. In the male priapism occurs, and occasionally satyriasis and seminal emissions. In the female, genital heat and irritation are characteristic, and sometimes abortion occurs. Genital gangrene may also result. Applied externally, heat, redness, pain, serous effusion, and vesication occur. The serum is albuminous, of a yellowish hue and alkaline reaction. If continued too long, or even until complete vesication has occurred, serious sloughing, and often gangrenous ulceration may occur, and particularly so after measles, typhoids, and in low vital states. Post-mortem examination reveals enlarged and engorged kidneys, with desquamative nephritis generally, though the parenchymatous form is sometimes observed. The bladder membranes are red, blistered, or ulcerated, or coated with false membranes. The gastric, as well as the urinary surfaces, are bloody, congested, or inflamed, and present exudates, or are gangrenous. Twenty-four grains of the powder or 1 ounce of the tincture have produced alarming symptoms, and even death. The smallest dose of the tincture of cantharides which has been known to destroy life was 1 ounce, equal to 6 grains of powdered cantharides. There is no known antidote to its poisonous effects, which must be treated on general principles.

Internally, cantharis, in small medicinal doses, acts as a stimulant to the urinary organs. In minute doses it relieves vesical irritation, and this is its best use. Cantharis is sometimes given in chronic gonorrhœa, gleet, leucorrhœa, seminal weakness, paralysis, and chronic inflammation of the bladder. In cystitis it is valuable to relieve teasing and tenesmus; and in the daytime enuresis of women, due to partial sphincter paralysis, it serves a useful purpose when given in minute doses. R Specific cantharis gtt. x; aqua, fl̄iv. Mix. A teaspoonful every hour. It has also been reputed useful in the anasaruous swellings succeeding scarlatina, diabetes, scaly cutaneous eruptions, chronic eczema, incontinence of urine, amenorrhœa, etc. Thirty drops of solution of potassa, given every hour, is said to be an effectual remedy in cantharidal strangury (see *Tinctura Cantharidis*).

Externally, cantharides cause redness, vesication, suppuration or sloughing, according to the length of contact with the integuments. Their most general use is to produce vesication. Blisters are sometimes beneficial in tic-doloreux, sciatica, local chronic inflammations, diseases of the brain, chest, and abdomen, to excite the languid action of vessels, in retrocession of exanthematous affections, and to rouse from general defective sensibility, as in typhoid fever. In their application to children, much care should be observed, especially in typhoid conditions, exanthemata, and where a tendency to sloughing exists. As a rule, blisters are not well thought of by the majority of our practitioners, though occasionally they are deemed of value. A piece of white paper soaked with cantharidin, which is greenish and liquid, laid on the part, and covered with a compress, and confined by means of a bandage, will vesicate in 3 or 4 hours. A vesicating oil has been recommended by E. Dupuy, prepared as follows: To 1 part of pulverized cantharides add, in a close vessel, a mixture of chloroform and castor oil, of each, by weight, 1½ parts; after some hours, transfer the ingredients to a glass apparatus, and displace the liquid in the usual way; it will amount to about two-thirds of the original bulk of the liquid employed. A few drops of this vesicating oil applied to the arm of an adult will produce a perfect blister in about 8 hours. It is easy of application on any surface, holds the vesicating agent free from the disagreeable concomitants of the ordinary fly blister, and retains the cantharides in a soluble state. Its action will probably be favored by the use of oil silk over the application of it to the skin. Cantharidal collodion is now generally preferred to other vesicating preparations of cantharis.

The dose of powdered cantharides is from ½ to 2 grains; of specific cantharis, 3 to 10 drops in water; tincture of cantharis, 10 to 60 drops, 4 times a day. For specific purposes the minute dose is preferred.

Specific Indications and Uses.—Vesical irritation, partial sphincter paralysis, with dribbling of urine and teasing desire to urinate, accompanied with tenesmus.

Vesicating and Other Medicinal Insects.—*Cantharis vittata*, Latrille; *Potato fly*.—The potato fly is common to this country, being found principally below 39° north latitude; it appears in July and August, and feeds upon the potato plant. Some seasons the fly exists in great numbers. It resembles the Spanish fly, though somewhat smaller, generally not exceeding half an inch in length. The potato fly, though not so much employed as the Spanish fly, is an excellent substitute for it; indeed, its effects are found to take place more promptly than with the foreign insect, which is probably due to its more recent state. There are several other species of the blistering fly in the United States, which are probably not at all inferior to cantharides, as the *Cantharis cinerea*, *C. atrata*, *C. marginata*, *C. vulnerata*, *C. melana*, *C. Nuttalli*, and other species. The *Mylabris bifusciata*, from the Cape of Good Hope contains a large amount of cantharidin (Braithwaite, *P. J. Proc.*, xviii, p. 246). *Mylabris cichorii* and *M. lunata* are also vesicant. The former is reputed, in Salamis, a cure for *hydrophobia*, and is thought to have been the ancient cantharis. This species and *M. phalerata*, have occurred in commerce as *Chinese blistering flies*. The *Lytta Gigas* of the East Indies has also been a commercial commodity. These species all contain considerable cantharidin.

These insects may be used in all cases as substitutes for the Spanish fly, as the property they all possess of blistering the skin when in contact with it, is due to the same constituent. The doses will also be the same.

Enas aser, of Spain, an insect of the beetle order, is said to be fully as great a vesicant as cantharis, and possesses besides, the advantage of operating almost painlessly and without any irritant action upon the renal organs (*Br. Med. Jour.*, 1882).

Blatta orientalis, Linné, *Cockroach*.—A revived ancient remedy, having been of late years brought forward in Russia as a non-irritating diuretic for *albuminuria* and other *dropical complaints*. The ancients employed a preparation of the insect in oil in various *cutaneous maladies*. The active principle, which is crystalline, and known as *antihydrotin* (or *turacantin*), is said to have been isolated by Bogomolow in 1876.

Formica rufa, Linné, *Red ant*.—This insect, which contains formic acid, and from which the latter was first isolated, enters into some European pharmaceutical preparations. Thus the German *Pharmacopœia* has *Spiritus Formicarum*: Alcohol 70, water 26, and formic acid 4 parts. Mix. Dose, 20 to 60 drops. It forms an acid liquid without color. A *Tinctura Formicarum* is made by taking alcohol 3 parts, and fresh, bruised red ants 2 parts. Digest. This produces a tincture having a brown color. Baths prepared by adding to the water a decoction of red ants was once used in *rheumatic* and *gouty complaints*. The *spiritus formicarum* is employed in Germany internally and locally in *paralytic* and other *nervous disorders*.

CAPSILLA.—SHEPHERD'S PURSE.

The dried plant of *Capsella Bursa-pastoris*, Moench (*Thlaspi Bursa-pastoris*, Linné).

Nat. Ord.—Cruciferae.

COMMON NAMES: *Shepherd's purse*, *Shepherd's sprout*.

ILLUSTRATION: *American Dispensatory*, 8th ed., Plate 5.

Botanical Source.—This is an annual weed, the stem of which is erect, striate, about 12 inches high, where the plants grow apart, but in rich soil, where they are in patches, the stems are often over 2 feet long, and reclining, but the thickness is increased very little. The branches are few, remote, and generally simple. The leaves are mostly borne in a thick radical cluster, at the base of the stem, and recline on the ground. They are from 3 to 6 inches long, and pinnatifid, with from 9 to 15 acute, wedge-shaped segments. The stem leaves are few, shorter than the internodes, and clasp the stems at the base of the branches. The lower stem-leaves are sagittate and dentate; the upper, linear and entire. The flowers are small, white, and borne in terminal racemes, which elongate as the flowers expand. The sepals and petals are 4, and the stamens are 6 and tetradynamous. The fruit is a flat, wedge-shaped pod, notched at the end, and divided by a narrow partition, into 2 cells, which contain numerous minute, oblong seeds.

History.—Shepherd's purse is a native of Europe, but is naturalized in almost every country of the world. In the United States it has become among the most common of yard weeds, growing in all sections of the country, and often forming large patches in waste grounds. It is especially luxuriant in the spring months, but the stem dies and the weed entirely disappears by the middle of summer. It is often eaten in the spring as "greens."

Capsella Bursa-pastoris has been used in domestic medicine since an early day. Culpepper refers to it in his *English Physician*, and the article is copied almost verbatim in subsequent works, until Lewis' (1761) *Materia Medica* cast discredit upon it as an astringent.

Description and Chemical Composition.—Shepherd's purse has been described above (*Botanical Source*). It has an herbaceous, unpleasant odor when fresh, if bruised, and a pungent, biting taste, which is lost by drying. The herb contains a resin and a volatile oil; the seeds yield proteid substances, a fixed oil, and a volatile oil said to be identical with the volatile oil of mustard.

Fig. 55.

Capsella Bursa-pastoris.

Fig. 56.

Fruit of Capsella.

But no satisfactory analysis has yet been made of its chemical constituents.

Action, Medical Uses, and Dosage.—Shepherd's purse appears to possess mild stimulating, astringent, and diuretic properties, and the fresh herb is decidedly more active than the dried. In *urinary derangements* of renal or cystic origin, and in *hematuria*, an infusion, and especially a tincture of the herb, will be found very efficient. It has likewise been used with some success as an expectorant and for the promotion of the catamenial flow in cases of *simple amenorrhœa*. It is a remedy for *chronic*

menorrhagia, with too frequent and too long-continued or constant, but almost colorless, flow. Associated with this condition is a frequent urging to urinate, and a deposit of phosphates. *Atonic dyspepsia* and *chronic diarrhœa* have been successfully treated with it. In *bleeding piles*, *diarrhœa*, and *dysentery*, it is stated to have been found beneficial. The dose of the infusion is from 2 to 4 fluid ounces, but its best forms for administration are the specific medicine, a tincture, or fluid extract of the herb; the dose of the tincture is 1 or 2 fluid drachms every 2 or 3 hours; of the fluid extract, from 20 to 60 minims; of specific capsella, 1 to 30 drops. The fresh herb, bruised and applied locally, has been effectual in *ecchymosis*, the result of blows, bruises, etc., and has been of service in *rheumatic pains*.

Specific Indications and Uses.—Chronic hemorrhages; menorrhagia with too frequent and long continued, or constant, colorless discharge; indigestion from atony; chronic diarrhœa; constant desire to urinate, with deposits of phosphates.

Related Species.—*Lepidium virginicum*, Linné, *Pepper-grass*, *Tongue-grass*.—An allied weed found in similar locations, has often been confounded with capsella, and has been lately figured for it in one of the medical journals. *Pepper-grass* has an erect, much-branched stem, about a foot high. The leaves are numerous and much more toothed than the stem leaves of capsella. The fruit is an orbicular, flattened pod, divided into 2 cells by a narrow partition, and containing 2 rather large seeds. *Pepper-grass* has a much sharper and more pungent taste than capsella. This and the next species probably contain a sulphuretted essential oil.

Lepidium intermedium, Gray; North America. *Wild pepper-grass*.

Lepidium sativum, Linné, *Garden pepper-grass*, *Garden cress*.—Habitat, Asia. Cultivated in Europe and America for table use. Contains a volatile, sulphuretted oil, and myrosin.

Lepidium campestre, Linné, *Yellow-seed*, and *Lepidium rudemale*, Linné, *Pepper-grass*.—Acrid plants with the same constituents as the preceding species.

Lepidium Iberis, Linné, *Pepper-grass*.—Southern Europe to northern Asia. Contains *lepidin*, a bitter, amorphous body obtained from the flowers and seeds (Leroux, 1837), and a volatile, sulphuretted oil.

Lepidium latifolium, Linné, *Broad-leaved pepper-wort*.—Properties similar to last species.

Thlaspi arvense, Linné, and *Thlaspi campestria*, Linné; Europe and America; known as *Penny cress* and *Mithridate mustard*; have brown, alliaceous seeds which yield an oil which Pless declares to be a mixture of oils of mustard and garlic.

Iberis amara, Linné, *Bitter candy-tuft*.—This plant has a herbaceous stem about a foot in height, with lanceolate, acute, somewhat toothed leaves, and white flowers, corymbed, but

becoming racemed. Siliques obcordate, narrowly emarginate; cells 1-seeded (W). This is a small annual, common to Europe, where it is admired as an ornamental plant; its beautiful white flowers appearing in June and July. The whole plant is reputed medicinal, the seeds more especially. In overdoses it occasions vertigo, vomiting, and purging, without accomplishing any valuable result. Medicinally, it appears to control nervous and vascular excitement, and has been found efficient in enlargement of the heart, and some affections of the air-tubes. It is also said to have been beneficially administered in rheumatic, gouty, and dropsical affections. The dose is from 1 to 5 grains of the powdered seeds.

Cochlearia officinalis, Linné, *Scurry-grass*, *Spoonwort* (*Herba cochleariae*). Europe. An acrid, bitterish, pungent plant when fresh. It contains the common plant constituents with a bitter body, tannin, salts, and gives rise to an essential oil (oil of scurry-grass), not pre-existent in the plant. A. W. Hoffmann demonstrated that it was composed mainly of butyl-iso-sulphocyanide ($\text{CSN}_2\text{C}_4\text{H}_9$). An oil of like composition, but having a different odor, is synthetically prepared from butylamine ($\text{C}_4\text{H}_9\text{NH}_2$). It differs also in the fusing point of the addition compound it forms with ammonia, 80°C . (192°F .), while the corresponding compound of the former ($\text{CS}[\text{NH}_2]\text{NH}[\text{C}_4\text{H}_9]$), melts at 135°C . (275°F .). The plant is sometimes used as a salad. It is stimulant, antiscorbutic, and diuretic. It is very valuable in scurry when eaten fresh, and the juice in water makes a good wash for spongy gums and buccal ulcerations.

Cardamine pratensis, Linné, *Cuckoo-flower* (*Herba nasturtii pratensis*).—A bitterish, pungent perennial found in Asia, Europe, and sparingly in North America. The showy flowers are of a white or rose color. The virtues of the plant are due to an essential oil, probably analogous to oil of mustard, as the seeds are said to contain myronic acid. The characteristics of the plant are lost upon drying. Diuretic, antispasmodic, and antiscorbutic. Has been used in chorea, asthma, dropsy, bronchitis, intermittent fever, laryngitis, and scaly skin affections, and locally to cancer and other sores.

Cardamine hirsuta, Linné. *Small bitter cress* of Europe and North America, and *Cardamine amara*, Linné, *Bitter cress* of Europe, have properties somewhat like the preceding.

Dentaria diphylla, Linné, of North America, and several other species of *Dentaria*, are known as *Toothwort* and *Peppercress*, the rhizomes of which have a pungent taste. Of the European species there may be mentioned the *D. enneaphylla*, Linné, and *D. bulbifera*; of the American, *D. laciniata*, Mühlenberg, *D. heterophylla*, Nuttall, and *D. maxima*, Nuttall.

Barbarea vulgaris, Robert Brown, *Yellow scurry-grass*, *Winter cress*, *Yellow rocket*.—Frequently cultivated as a salad, as is also the *Barbarea præcox*, R. Brown, or *Early winter cress*. Both are found in Europe and North America.

Nasturtium officinale, R. Brown (*Sisymbrium Nasturtium*, Linné), *Water cress*.—Common in wet places. Pungent and bitterish when fresh, and contains a sulphuretted essential oil analogous to that of mustard. A plant having similar properties is the *Nasturtium palustre*, De Candolle, or *Marsh cress*.

Capparis spinosa, Linné. *Nat. Ord.*: Capparidaceæ. *Caper*.—The caper bush is a trailing shrub growing in northern Africa and Southern Europe. Formerly the root-bark was official. It has a bitterish, sub-acrid, aromatic taste. The bluish-green, entire, round-oval leaves also possess the bitter, acrid taste. The plant is chiefly cultivated, however, for its flower buds, which, when prepared with salt and pickled in vinegar, form a much esteemed condiment. The buds are about the size of a pea, have 4 each of petals and sepals, many stamens, a single ovary, and a sharp, hot taste. When pickled they are sour and burning to the taste. Besides tannin and a bitter body, the root-bark contains a pungent, saponin-like principle. The buds contain an alliaceous, volatile oil, and a yellow coloring body thought to be rutin (*rutic acid*) (see *Ruta*). Pickled capers were formerly employed in scurry, and the root-bark in rheumatic complaints and amenorrhæa.

Capparis ferruginea, Linné, and *Capparis cynophallophora*, Linné. West Indies. Root-bark vesicant and diuretic; fruit used in scurry; all parts have been used in hysteria and to expel worms. The Eastern species, *Capparis Egyptiaca*, Lamarck, and *Capparis coriacea*, have similar uses. The African fruit of *Capparis lodada*, Robert Brown, and other species, are used as substitutes for pepper.

Reseda luteola, Linné. *Nat. Ord.*: Resedaceæ. *Dyer's weed*, *Weld*. Europe. Naturalized in the United States. The root of this plant is conical, and resembles in taste and odor the garden radish. It contains allyl-sulphocyanate ($\text{C}_3\text{H}_5\text{CNS}$), or volatile oil of mustard (Volhard). A persistent bitter taste is imparted by the herb. It contains silky yellow crystals of a coloring body, *luteolin* ($\text{C}_{20}\text{H}_{14}\text{O}_5$). It is feebly bitter and somewhat astringent. It is quite soluble in alcohol, and less so in ether and water. Fused with caustic potash it yields protocatechuic acid, phloroglucin, and carbon dioxide. It is now used only in dyeing; formerly it was employed to increase the renal and cutaneous secretions.

Reseda odorata, Linné, *Mignonette*. Its root also contains the volatile oil of mustard, or allyl-sulphocyanate.

Polunisia graveolens, Rafinesque. *Nat. Ord.*: Capparidaceæ. North America, from Vermont to Arkansas, in gravelly soil. An annual bearing small yellowish-white flowers and ternate leaves, and many-seeded, oblong-lanceolate pods. The whole plant is viscid-pubescent and has a pungent taste and disagreeable odor. It is an irritant.

Gynandropsis pentaphylla, De Candolle. *Nat. Ord.*: Capparidaceæ. East Indies. Naturalized in this country, growing in waste places from Virginia to Georgia. Flowers white; capsule linear and containing numerous seeds, which have been used like mustard.

Tropæolum majus, Linné, and *Tropæolum minus*, Linné. *Nat. Ord.*: Geraniaceæ. *Garden nasturtium*, *Indian cress*. Natives of Peru. Cultivated for ornament and for the buds and immature fruits, which are used in pickling.

Other Cresses.—*Spilanthes oleracea*, Jacquin (Compositæ), is *Para cress*; *Arabis lyrata*, Linné (Cruciferae), is *Rock or wall cress*; and *Senebiera didyma*, Persoon, is *Wart cress* and *Swine cress* (see also *Sinapis*).

CAPSICUM (U. S. P.)—CAPSICUM.

"The fruit of *Capsicum fastigiatum*, Blume" (U. S. P.), (*Capsicum minimum*, Roxburgh).

Nat. Ord.—Solanaceæ.

COMMON NAMES: *Cayenne pepper*, *African pepper*, *Bird pepper*, *Guinea pepper*, or *Chillies* (in England), *Red pepper*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 188.

Botanical Source.—This plant differs from the next species in being a shrub instead of an herbaceous annual, and in having the corolla lobes more sharply pointed, and differs also in fruit and seed. The fruits, 2 or 3 in number, are borne where the branches fork. They are from $\frac{1}{2}$ to less than 1 inch long, narrow, somewhat oblong-ovoid, erect, sub-cylindrical, of bright scarlet-red color, and are borne on a flat cup-like calyx. The fruit is hot, extremely pungent, or biting, and has a characteristic odor. Its seeds are smaller than those of *Capsicum annuum*, Linné, a description of which is here added.

Capsicum annuum, Linné, *Pod pepper*.—An annual plant, of a dark-green color, almost smooth, and growing 1 or 2 feet high. The stems are herbaceous, angular, furrowed, and branched. The leaves are ovate or oblong, acuminate, entire, on long petioles, and sometimes hairy on the veins underneath. The flowers are white, solitary, axillary, pendulous, with dark-colored oblong anthers; the calyx angular, erect, persistent, with 5 short acute lobes; the corolla hypogynous, rotate, 5-lobed; the corolla-tubes very short; the lobes spreading. Stamens 5; ovaries ovate; style filiform; stigma blunt. The fruit is of various forms, round, oblong, cordate, or horned, and either of scarlet or yellow pods, smooth, shining, and 2-celled, containing numerous flat, dry, reniform, very acrid seeds (L.).

History.—There are several species of *Capsicum*, all varying more or less in their degrees of pungency. The only plant now recognized by both the *United States Pharmacopœia* and the *British Pharmacopœia* is the *C. fastigiatum*, Blume. The botanical description of the *Capsicum annuum*, Linné, is here included, because often employed for the same purposes as the official species, and on account of its being largely cultivated in American gardens. Furthermore, it is the official species of the *Pharmacopœia Germanica*. It undoubtedly forms a large part of ground red pepper. The official capsicum grows on the Guinea coast and the East Indian Isles.

There are several other species of *Capsicum*, as the *C. frutescens*, Linné; *C. longum*, Linné; *C. cordiforme*, Miller; *C. grossum*, Willdenow; *C. chlorocladum*, De Candolle; *C. cerasiforme*, Willdenow, etc. Many of them, however, are regarded as mere varieties. They are natives of the East and West Indies, and of most hot climates throughout the globe. Several species are cultivated in the United States, flowering from June to September, and maturing their fruit in the latter part of autumn. A good variety is found indigenous in Texas. They all agree in producing a shining vesicular berry of a greenish, yellowish, cherry-red, or most generally scarlet color, consisting of a thin, fleshy, inflated, bilocular, or trilocular capsule, and many small, flat, reniform seeds. The Bird pepper (*C. fastigiatum*, Blume) is usually deemed the best. The *C. annuum*, Linné, is the most extensively used in this country. The large ovate peppers are pickled while green. All the varieties of capsicum have a faint, characteristic odor, and an extremely hot, acrimonious taste, which in some is so intense that the smallest fragment, when chewed, will excite a sensation of intolerable burning in the mouth. This acidity is imparted to hot water, ether, spirit, vinegar, and fixed oils. Powdered cayenne pepper, of good quality, is of a bright color, varying from a beautiful red to a brown or yellow, which is considerably discolored by the action of light. Insects will attack it.

Adulterations.—Powdered capsicum is sometimes adulterated with pulverized woods or barks, red ochre, and minium (red lead). This last may be discovered, by steeping the capsicum in nitric acid diluted with water, then adding

sodium sulphate to the filtered solution, which gives a white deposit, if the metallic oxide is contained in it.

Description.—"Oblong-conical, from 10 to 20 Mm. ($\frac{1}{2}$ to $\frac{3}{4}$ inch) long, supported by a flattish, cup-shaped, 5-toothed calyx, with a red, shining, membranous and translucent pericarp, enclosing 2 cells, and containing flat, reniform, yellowish seeds attached to a thick, central placenta. It has a peculiar odor, and an intensely hot taste"—(U. S. P.).

Chemical Composition.—In 1816 and 1817, Braconnot and Bucholz extracted what they believed to be the active constituent and called it *capsicin*. According to Hager (*Handb. Pharm. Praxis*, 1886), Braconnot gives the following composition of 100 parts of Spanish pepper: Pungent oil, 1.9; wax, combined with red coloring matter, 0.9; brown amylaceous matter, not blued by iodine (pectic acid, according to Berzelius), 9.0; gum, 6.0; nitrogenous matter, 5.0; woody fiber, 67.0; potassium citrate, 6.0; potassium phosphate and chloride, 3.4. *Capsicin* of Braconnot and Bucholz is obtained by making an alcoholic extract of capsicum, and then digesting this in ether, filtering and evaporating the ethereal solution. It is a thick liquid, of a yellowish-red, or reddish-brown color, of an overpowering acrid taste, volatilizes at a moderate elevation of temperature, and disengages so acrid a vapor, that $\frac{1}{2}$ grain will cause every person in a large room to cough and sneeze violently. Water and vinegar slightly dissolve it, but ether, oil of turpentine, alcohol, chloroform, and the caustic alkalies readily dissolve it. With barium oxide it forms a solid, acrid combination (P.—T.). F. Victor Heydenreich (*Amer. Jour. Pharm.*, 1858), concluded that the *capsicin* of Braconnot consisted of two active oils with an inert fatty substance, and that the true *capsicin* consisted of these oils without the fatty matter. In 1873, Buchheim pronounced *capsicol* to be the active principle which, however, was probably not quite pure (Flückiger). Mr. J. C. Thresh (*Pharm. Jour. and Trans.*, 1876) succeeded in isolating the probably pure acrid principle—a colorless crystalline substance present in small amount only, and difficult to obtain pure—to which he gave the name *capsaicin* ($C_{26}H_{48}O_2$). It is intimately associated with a fatty material, composed largely of palmitic acid. It is extremely rubefacient, fuses at 59° C. (138.2° F.), sublimes at 115° C. (239° F.), and, when heated, gives off intensely acrid fumes. Alcohol, ether, hot disulphide of carbon, benzin, diluted alkalies, and amylic alcohol dissolve it. In 1889, Arthur Meyer demonstrated that the placenta of *Capsicum annuum* is the carrier of the acrid principle (*capsaicin*). This isolation was effected by extracting with boiling ether, evaporating the solvent, mixing the residue with oil of sweet almonds (to retain the red coloring matter), extracting with 70 per cent alcohol, evaporating and dissolving the residue in solution of caustic potash free from carbonate, filtering and passing into the filtrate carbonic acid to saturation. After standing for some days the *capsaicin* crystallizes out and is purified by washing with water and cold benzin. This method (which is that of Thresh) yielded 0.9 per cent of *capsaicin* in 110 Gm. of placenta, obtained from 5000 Gm. of red pepper (*Amer. Jour. Pharm.*, from *Pharm. Zeitung*). Felleter (1868), also Thresh (*Amer. Jour. Pharm.*, 1876), and later Flückiger, isolated a volatile, but non-acrid alkaloid of coniine-like odor. A very small portion of a crystallizable fat, occurring in white crystalline tufts, and associated with essential oil, to which the odor of capsicum is probably due, was obtained by Flückiger (*Pharmacognosie*, 1891). It had a non-acrid, spicy taste, and resembled parsley oil.

Action, Medical Uses, and Dosage.—Capsicum is a pure, energetic, permanent stimulant, producing in large doses vomiting, purging, pains in the stomach and bowels, heat and inflammation of the stomach, giddiness, a species of intoxication, and an enfeebled condition of the nervous power. The infusion is much used in *colds*, *catarrh*, *hoarseness*, etc. In *atonic dyspepsia* and *catarrhal gastritis* it stimulates the nerves of the stomach, promotes the secretion of the digestive juices, and assists peristaltic motion. As an internal remedy some have advanced the theory that it is destroyed during digestion. Perhaps, when ingested with food, this may be partially true, but, if so, how do we account for its remarkable activity in sustaining the nervous system when given in *delirium tremens*, and the power it has in steadying the patient and promoting sound sleep? That its effects are partly due to its stimulating action upon the gastric membranes is unquestionable, but its entire effects can not be due to this cause alone. The same may be

said of its action in *congestive intermittent* and *remittent fevers*. Some have thought to attribute its action in *congestive chill* to its effects upon the solar plexus. It forms an excellent addition to quinine in *intermittents*, where there is a deficiency of gastric susceptibility, and it has been asserted that but one-half the quinine will be needed when combined with capsicum.

Capsicum is the very best agent that can be used in *delirium tremens*. It enables the stomach to take and retain food, and the best form of administration is a strong beef tea, or strong soup made hot with red pepper. There is no danger of giving an overdose, as a wonderful quantity (even a drachm of red pepper) may be swallowed with evident pleasure and without ill results by a confirmed dipsomaniac. In the *atonic dyspepsia of dipsomania* it takes the place of alcoholic stimulants, removing the craving for alcoholics and sense of sinking at the pit of the stomach, prevents the morning sickness and vomiting, restores gastric tone and promotes the digestion of wholesome food. It should be administered whenever the desire for drink comes on. Prof. Locke recommends for *delirium tremens* doses of 10 to 40 grains of capsicum every 3 hours, or liberal doses of compound tincture of myrrh and capsicum. When the craving for drink occurs he administers 20 drops of the following in water: R Comp. tinct. of myrrh, flʒj; specific nux vomica, flʒss. Mix.

Capsicum is said to reduce irritation and increase capillary activity in *chronic renal congestion*. It affects the bladder and rectum similarly and may accordingly be a remedy for *diarrhœa*, *constipation*, *piles*, and in *dysentery*, where the stools are bloody, the mucus tenacious, with tenesmus and burning, and associated with tenesmic action of the bladder. These cases are those in which there is a lax habit of body with feeble digestion. Other indicated remedies may be given with it. For *hemorrhoids*, with torpor, constipation, or relaxation, it is a good remedy. Prof. Locke suggests for this state, when not recent nor associated with rectal burning: R Capsicum, gr. ij; aloes, gr. ʒ. Mix. Make 1 pill.

Capsicum should not be forgotten in *low fevers*, where there is dryness and constriction of the tissues, and the tongue is dry and harsh and there is but little buccal or salivary secretion. Here it is a very valuable adjuvant to other indicated drugs. Though a stimulant, the general circulation is but little increased by capsicum. *Paralytic states*, without organic lesions, and with great digestive and nervous torpor, are often greatly improved by capsicum. In *Asiatic cholera* and *angina pectoris*, with cold extremities, cool perspiration, and great nervous prostration, it is asserted a saving agent.

Capsicum meets the debility of young and old, but is particularly useful in old people when the body-heat is low, vitality depressed, and reaction sluggish. *Tired, painful muscles*, *stiffened joints*, and relaxation of any part are common conditions in the elderly that are, in a measure, rectified by capsicum. Homœopaths suggest its use in *pneumonia* when abscesses threaten. *Flatulence* in dyspeptic states may be dispelled by capsicum.

A preparation made by adding ½ ounce of powdered capsicum and 2 drachms of salt, to ¼ pint each, of vinegar and water, has been found an excellent anti-emetic, in all cases of *vomiting* or *nausea*. To be given in tablespoonful doses as often as required. It has received the name of ANTI-EMETIC DROPS. Capsicum has been also used in *spasmodic affections*, *passive hemorrhages*, especially uterine, and, when combined with the compound powder of ipecacuanha will, in many instances, promptly arrest *hemorrhage after parturition*.

Externally, the infusion and tincture have been found valuable as a stimulating gargle in the *ulcerated throat of scarlatina*, or in *chronic cynanche tonsillaris*; also as a counter-irritant, as an application to *indolent ulcers*, in *chronic ophthalmia*, and in *chronic or indolent ulceration of the cornea*. If used early in *tonsillitis*, with relaxation, it may abort the trouble, but if it does not its use should be discontinued until the active inflammation has subsided. *Hoarseness*, from atony of the vocal cords, is relieved by it, and it is a remedy for *relaxed uvula*. It enters into various tinctures and liniments. The concentrated tincture of capsicum has been highly recommended in the treatment of *chilblains* and *toothache*. In the former, a piece of sponge or flannel must be saturated with it, and rubbed well over the seat of the chilblain, until a strong tingling and electrical feeling is produced. This application should be continued daily, until the disease is removed; relief

will be experienced on the very first application, and frequently there will be a total removal of the disease after the second or third application. This, however, will depend upon the severity of the case.

Powdered capsicum, sprinkled inside the stockings, was a favorite prescription with Prof. Scudder for *cold feet*. This medicine possesses an extraordinary power in removing congestion by its action upon the nerves and circulation; if the skin is not broken, it never causes excoriation by rubbing with it. For *toothache* from dental caries, place 1 or 2 drops of the tincture on cotton, and apply to the affected part; the relief will be immediate. *Tinctura Capsici Concentrata* is prepared by macerating 4 ounces of capsicum in 12 fluid ounces of rectified spirit for 7 days; then filter.

The *etheral oil of capsicum*, prepared by the evaporation of a saturated ethereal tincture of the pods, is sometimes used as a rubefacient. It is of a brilliant yellowish color, with a peculiar odor and aromatic taste, and filled with crystals of solid fatty oil of curious dendroid forms (see *Oleoresina Capsici*).

Capsicum may be used wherever a pure stimulant is indicated, in all cases of diminished vital action, and may be combined beneficially with other remedies, in order to promote their action, as emetics, cathartics, diaphoretics, tonics, etc. Dose of the powder, from 1 to 6 grains; of the tincture, from $\frac{1}{4}$ to 1 fluid drachm.

Specific Indications and Uses.—Marked depression and debility; atonic dyspepsia of drunkards; delirium tremens; colic, with abdominal distension; congestive chills; cold extremities, with blanched lips and small, weak pulse; congestion, with capillary atony; tongue dry and harsh, and buccal and salivary secretions scanty, in fevers; chronic hemorrhoids, from relaxation.

CARBO ANIMALIS (U. S. P.)—ANIMAL CHARCOAL.

“Charcoal prepared from bone”—(U. S. P.).

SYNONYMS: *Bone-black, Ivory-black, Spodium, Carbo ossium, Ebur ustum.*

Preparation and Chemical Composition.—When bones, or indeed any animal substances, are exposed to a red heat, with limited access of air, in covered iron vessels, or retorts, until they cease to emit any vapor, the residue is animal charcoal. *Bone spirit*, an ammoniacal fluid, is also obtained by this process of destructive distillation, from the vapor which passes over. The animal charcoal or bone-black thus obtained is impure, and though serviceable for some purposes in pharmacy and in the arts, yet it will be found unfit for many others unless purified. The impurities it contains are mainly phosphate and carbonate of calcium, with carbide and silicide of iron, and sulphides of iron and calcium. The amount of inorganic constituents is as high as 85 per cent, leaving for pure carbon not more than 15 per cent. Sand also is frequently present.

CARBO ANIMALIS PURIFICATUS (U. S. P.), Purified animal charcoal.—“Animal charcoal in No. 60 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; hydrochloric acid, three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; boiling water, a sufficient quantity. Introduce the animal charcoal into a capacious flask, add two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.], of hydrochloric acid, and one hundred cubic centimeters (100 Cc.) [3 fl. 3, 183 M], of boiling water, and connect the flask with an upright condenser. By means of a sand bath keep the mixture gently boiling during 8 hours. Then add five hundred cubic centimeters (500 Cc.) [16 fl. 3, 435 M] of boiling water, transfer the mixture to a muslin strainer, and when the liquid has run off, return the charcoal to the flask. Add to it one hundred cubic centimeters (100 Cc.) [3 fl. 3, 183 M] each, of hydrochloric acid and of boiling water, boil for 2 hours; again add five hundred cubic centimeters (500 Cc.) [16 fl. 3, 435 M] of boiling water, transfer the whole to a plain filter, and when the liquid has run off, wash the residue with boiling water, until the washings give only a faint cloudiness with silver nitrate test solution. Dry the powder in a drying oven, and immediately transfer it to well-stoppered vials”—(U. S. P.).

Description and Tests.—I. **CARBO ANIMALIS (U. S. P.), Animal charcoal.**—According to the Pharmacopœia, carbo animalis should be in “dull black, granular fragments, or a dull-black powder, odorless, nearly tasteless, and insoluble in

water or alcohol. When ignited, it leaves a grayish or yellowish-white ash, amounting to about 85 per cent of the original weight of the portion taken, which should have been previously dried at 120° to 125° C (248° to 257° F.), to a constant weight. The ash should be soluble in hydrochloric acid with the aid of heat, leaving not more than a trifling residue. If 1 Gm. of animal charcoal be boiled for several minutes, with a mixture of 3 Cc. of potassium hydrate T.S. and 5 Cc. of water, the filtrate should be colorless or nearly so (evidence of complete carbonization)"—(U. S. P.).

II. CARBO ANIMALIS PURIFICATUS (U. S. P.), *Purified animal charcoal*.—"A dull black powder, odorless, tasteless, and insoluble in water, alcohol, or other solvents. If 2 Gm. of the powder be ignited at a red heat with free access of air in a broad shallow porcelain or platinum dish, it should not leave a residue weighing more than 0.08 Gm., or 4 per cent of the original weight (limit of silicates and other fixed inorganic matter). If 1 Gm. of the powder be boiled with a mixture of 3 Cc. of potassium hydrate T.S. and 5 Cc. of water during 3 minutes, the filtrate should be colorless (evidence of complete carbonization)"—(U. S. P.).

Purified animal charcoal somewhat resembles vegetable charcoal, but is more dense, and less combustible. Upon long exposure to the atmosphere it absorbs moisture, and loses its decolorizing properties, for which it is chiefly employed. The nature of its decolorizing action is not well understood, though supposed to be largely owing to its peculiar porous texture. It not only removes the coloring principle of vegetable infusions and tinctures, but is likewise capable of absorbing bitter principles, and when purified, abstracts iodine and numerous salts from their watery solutions. When carelessly purified, animal charcoal may contain phosphate and carbonate of calcium; these impurities may be detected by effervescence with hydrochloric acid, and the precipitation of phosphate of calcium from the filtered solution by ammonia, or of carbonate of calcium by carbonate of ammonium. H. Leplay and J. Cuisinier have given a method of restoring, by easy and speedy methods, the absorbing properties that animal charcoal loses by use (*Amer. Jour. Pharm.*, 1862, p. 551, from *Chem. News.*, 1862).

Action, Medical and Pharmaceutical Uses, and Dosage.—Its principal uses are to decolorize various organic matters, as strychnine, cinchonine, etc., and to purify syrups and glucose. It is used extensively in sugar refineries for this purpose. It is also used to remove from spirit prepared from grain, its grain- or fusel oil. It has likewise been highly extolled as an internal remedy, in doses of $\frac{1}{2}$ grain to 3 grains, twice a day, in *scrofulous* and *cancerous affections*, *goitre*, *obstinate chronic glandular indurations*, etc. Not used in this country medicinally. Like vegetable charcoal, it destroys the odor of putrid animal matter. Dr. A. B. Garrod, in a paper read before the Medical Society of London, Nov. 17, 1846, recommended purified animal charcoal in cases of *poisoning* by opium, strychnine, aconite, belladonna, stramonium, tobacco, hemlock, etc. First remove as much of the poison as possible by means of the stomach pump, or emetics combined with the antidote, and then give a large quantity of the purified animal charcoal, diffused in warm water; a vegetable emetic must not be used, as the charcoal would destroy its emetic properties. He considered this agent useful as an antidote to arsenous acid. According to M. Lebourdais, animal charcoal may be used for the purpose of procuring many of the active constituents of vegetable medicines (see *London Pharm. Jour.*, 1851, p. 447).

Related Product.—CARBO CARNIS, *Meat charcoal*. This product is prepared by roasting 3 parts of lean veal with 1 part of bones (small ones preferred). The operation is conducted in a covered apparatus, and continued until inflammable vapors cease to be evolved. When cold, it is to be powdered and put into a well-stoppered vial.

CARBO LIGNI (U. S. P.)—CHARCOAL.

"Charcoal prepared from soft wood, and very finely powdered. It should be kept in well-closed vessels"—(U. S. P.).

SYNONYMS: *Carbo vegetabilis*, *Carbo preparatus*, *Wood charcoal*, *Carbo e ligno*.

Preparation and Purification.—Wood or vegetable charcoal for pharmaceutical or other purposes is made by the well-known process, too familiar to be

described. For medicinal purposes, charcoal as ordinarily prepared is not pure enough for internal use. It may be purified, according to Lowitz, by placing fine common charcoal in a crucible, and, when filled, cementing on a cover containing several orifices. This is to be exposed to a red heat, which must be continued as long as flame of a blue color emerges from the orifices of the cover, and when this has stopped remove from the fire, and when cold place the charcoal as soon as possible in glass vessels, which must be kept well closed. The best charcoal for medicinal purposes is that which is properly prepared from young willow shoots, and is known in trade by the name, "*Willow charcoal*."

Description.—In shape and texture charcoal resembles the particular wood from which it is prepared. As used in medicine and pharmacy it is in pulverized condition. According to the *U. S. P.* it should be "a black, odorless, and tasteless powder, free from gritty matter. If 1 Gm. of charcoal be boiled with a mixture of 3 Cc. of potassium hydrate T.S., and 5 Cc. of water for several minutes, the filtrate should be colorless, or nearly so (evidence of complete carbonization)"—(*U. S. P.*). Wood charcoal is an excellent conductor of electricity, but not of heat. It corrects the fetor from putrid animal matters, and decolorizes vegetable infusions, but not so promptly as the animal charcoal. It decomposes many metallic compounds, when heated with them, by depriving them of their oxygen. If kept in the air its weight is speedily augmented in consequence of its affinity for moisture, even to the amount of from 10 to 15 per cent. Combustion produces carbonic acid gas, leaving behind an ash composed of earthy matters and carbonate of potassium. Charcoal has the property of absorbing gases, which it accomplishes to an extent varying with the grade of charcoal, and with the gas absorbed. For this purpose it should be freshly prepared. Generally speaking, 1 volume of charcoal will absorb 10 volumes of oxygen, 35 volumes of carbonic acid gas, 55 volumes of hydrogen sulphide, and 100 volumes of ammonia. It is not so useful for decolorizing pharmaceutical preparations as animal charcoal.

Action, Medical Uses, and Dosage.—As a medicine, charcoal should always be purified. "Charcoal is generally described as possessing antiseptic properties, while the very reverse is the fact. Common salt, corrosive sublimate, arsenous acid, alcohol, camphor, creosote, and most essential oils, are certainly antiseptic substances, and, therefore, retard the decay of animal and vegetable matters. Charcoal, on the contrary, greatly facilitates the oxidization, and, consequently the decomposition of any organic substance with which it is in contact. It is, therefore, the very opposite of an antiseptic" (Dr. Stenhouse). It does, however, render the gases evolved latent. It acts as an absorbent (both fluids and gases) and disinfectant. Its internal employment will be found useful in those *digestive derangements* which are associated with offensive breath and disagreeable belchings; also to correct the fetid condition of the stools in *dysentery*. It is also useful in *acidity of the stomach*, *flatulency*, and in the nausea and constipation attending *pregnancy*. It is also very useful in internal heat and irritation of the stomach, with acidity; *sick headache*; *diarrhœa*; *cholera infantum*, etc. In cases of *sick headache*, due to gastric acidity or derangement, and which are ushered in with blurred vision, photopsia, and finally nausea and intense headache, I have found a drachm of charcoal mixed in a little syrup, to which is then added about a gill of water, and 10 or 12 drops of ether, to afford prompt relief; in very obstinate cases, the dose may require to be repeated 2 or 3 times, every 20 or 30 minutes (J. King). In some cases charcoal may be advantageously combined with the subnitrate of bismuth as a sedative; and where a laxative action is required, rhubarb may be beneficially added to it. *Bilious colic* is said to have been cured by it, in doses of 1 drachm in 2 fluid ounces of burnt brandy, repeated as required. Externally, it may be used in poultices to correct fetor of *ulcers*, arrest *gangrene*, etc., and is efficient in many *cutaneous diseases*. It absorbs foul gases generated in vaults, sewers, etc. It is also a useful hemostatic, having arrested *epistaxis* when subsulphate of iron had failed. "The specific use of charcoal," says Dr. Scudder (*Spec. Medication*) "is to arrest hemorrhage from the bowels. It has been used in enema, ʒss to ʒj, finely powdered, to 4 ounces of water, thrown up the rectum. Why this checks it I can not tell; that it does it, I have the evidence of my own eyes. For several years I have employed the second decimal trituration as a remedy for *passive hemorrhage*, with most marked benefit. I

employ it in threatened hemorrhage during *typhoid fever*; in *menorrhagia*, especially when chronic; in *prolonged menstruation*; the watery discharge that sometimes follows menstruation; *hemorrhage from the kidneys*; *hemorrhage from the lungs*; and in some cases of *leucocythemia*. A good indication for this remedy is a small, pallid tongue with lenticular spots, and with this it may be given in any form of disease." It occasionally enters into tooth-powders, and may be used with advantage to correct the fetor of the mouth, and cleanse the teeth. In such cases, the charcoal prepared from bread is the best, as it contains no gritty particles. Water may be purified by passing it through charcoal mixed with sand. The ordinary dose of charcoal is from 20 grains to 2 drachms, 2 or 3 times a day, in water, milk, or burnt brandy, repeating it according to indications. For specific uses the 1 x, or 2 x trituration, 5 to 10 grains, as often as necessary.

Specific Indications and Uses.—A pallid, expressionless tongue, with slight coat and lenticular spots, or slight coat lifting in patches; pallid skin; feeble pulse; tumid, doughy abdomen; tendency to hemorrhage; frequent, foul, hemorrhagic bowel discharges; passive hematuria; passive hemoptysis; salty taste in the mouth. The remedy for asthenic hemorrhage and profuse secretion.

Carbon and Its Modifications and Related Products.—CARBON. Symbol: C. Atomic Weight: 11.97. A quadrivalent, sometimes bivalent, element, widely diffused over the earth. It is found in the earth as free carbon, especially as *graphite* (plumbago), and in crystallized, transparent condition, as *diamond*. In an impure amorphous form it exists as *coal*. It combines with oxygen to produce carbonic anhydride (CO_2), or carbon dioxide, existing in this form in considerable quantity in the atmosphere, and in effervescing mineral waters. In mineral formations it exists combined with other substances, forming carbonates. It is found very extensively in organic matter, both animate and inanimate; in fact, the study of so-called organic chemistry may be said to be the study of carbon and its compounds and derivatives. The black residue left when organic matter is heated, with limited access of air, is produced by freeing the carbon, or the process of carbonization, as it is called. Carbon occurs in 3 allotropic forms, viz.: Diamond, graphite, and amorphous carbon.

I. DIAMOND, one of the hardest bodies known, is a crystallized carbon. Electricity is not conducted by it. If heated, excluded from the air, it remains unaltered at very high temperatures, but if heated in the air or to whiteness in oxygen, combustion ensues, with the production of carbon dioxide. The diamond is the purest form of carbon. Its density is 3.5. It is found chiefly in India, Borneo, Brazil, and South Africa, while some diamonds have been unearthed in North Carolina and Georgia. An impure carbon-mass, containing both oxygen and hydrogen, and known as *anthracite diamond*, or *black diamond*, is said to be even harder than the true diamond.

II. GRAPHITE. *Plumbago*, or *Black lead*.—This next purest form of carbon presents a totally different aspect from the diamond. It is found abundantly in some localities, especially in England, and in New York, Massachusetts, and Canada. The purest form is said to come from the Borrowdale mines in England. In granite and other mineral formations it occurs sometimes in large lumps. It is crystalline, forming plates, which are hexagonal, soft, unctuous to the feel, usually of a dull-gray, or grayish-black color, and has a density ranging from 1.9 to 2.25. Graphite is infusible, and is a good conductor of the electric current. It is largely employed in the arts in the making of lead-pencils, crucibles, stove-polish, etc. The name *black lead* should be discarded, as graphite has no connection chemically, or otherwise, with lead.

III. AMORPHOUS CARBON.—This form of carbon is well known as *coal*. The purest variety is known as *anthracite*, or *hard coal*. The next variety is known as *bituminous*, or *soft coal*, a form containing considerable hydrogen. When subjected to red heat in closed retorts, volatile hydrocarbons and tar are given off, leaving *coke* as a residue. Coke is a fairly pure carbon, intermixed with the mineral components of coal. Anthracite coal contains about 90 per cent of carbon; bituminous coal, about from 75 to 90 per cent; and amorphous carbon (*lignite*), about 65 per cent. *Lampblack*, another amorphous carbon, is the result of the imperfect combustion of resinous, fatty and waxy material, the *smoke* so produced condensing as finely divided carbon, or *lampblack*.

FULIGO LIGNI. *Soot*, *Wood soot* (*Fuligo splendens*).—The best soot for medicinal purposes is that which is gathered within an air-tight wood stove and its pipe; that which is collected from a clean chimney or ordinary stove-pipe, where hard wood alone is burned, will ordinarily answer, if it be free from ashes and calcium compounds. Soot has a peculiar odor, somewhat resembling that of creosote, and a nauseously empyreumatic, more or less bitter and acrid, saline taste. Its infusion in water is of a dark-brown color, with the characteristic odor and taste of soot. It is a complex mixture of distilled products from the imperfectly burnt wood, ashes, or other fixed matters, carried up the chimney by the current of air. It consists of an empyreumatic resin (*pyretin*), combined with *acetic acid*, which also saturates the bases, calcium, potassium, and magnesium, of the ashes carried up the chimney. Acetate of ammonium, chloride of calcium, sulphate of calcium, extractive matter, creosote, carbon, silica, sesquioxide of iron, and nitric acid, have all been found in soot. The solution of soot, evaporated, furnishes a dark-colored extract, which, on being re-dissolved in water, forms a dark-brown solution. About 0.44 of soot is insoluble. It probably owes its virtues largely to

creosote. Soot has deodorant and disinfectant properties, and may be employed in vaults, etc., to overcome foul effluvia.

Internally, soot was formerly much employed, and found valuable in all forms of disease attended with *acidity of the stomach*. A powder, composed of 1 part each of powdered rhubarb and soot, and half a part of bicarbonate of potassium, will be found invaluable in all such cases, removing acidity and a tendency to constipation. It may be given in doses varying from 3 to 12 grains, 3 times a day, or in sufficient quantity to cause 1 or 2 evacuations from the bowels daily. An infusion of soot, made so as not to be unpalatable, is very beneficial in *inflammation of mucous membranes*, and in *hysteria*. A strong decoction of soot, used as an injection into the rectum, has caused the expulsion of *ascarides*; its use should be continued for several days in succession; injected into the bladder it has been of service in *chronic inflammation of the bladder*; it should be injected twice a day for some days. It possesses no antispasmodic virtues, further than neutralizing the acidity of the stomach, to which the spasmodic action is owing. Combined with extract of geranium, in the proportion of 2 parts to 1 of the astringent, it will prove valuable in *diarrhœa* and *cholera morbus of children*; in *summer-complaint*, 1 part of the dried extract of leptandra, and $\frac{1}{2}$ part of camphor or ginger may be added to the above. The infusion or decoction may be made by adding 1 or 2 ounces of soot to a pint of water, macerate or boil for $\frac{1}{2}$ hour, and filter. Dose, 1 or 2 fluid ounces, 2 or 3 times a day.

Externally, Prof. King used the *Unguentum Fuliginis* in cases of recent and extensive burns, with almost immediate relief. It must be spread on raw cotton and applied over the part. The ointment is also efficient in various *cutaneous disorders*, especially those of an *erysipelatous character*, *tinea*, *fungus*, *cancreous* and *syphilitic ulcers*, *pruritis vulvæ*, *specks on the cornea*, *scrofulous ophthalmia*, *severe burns and scalds*, etc. In some of these diseases the decoction will answer. In many ophthalmic diseases, a strong decoction of equal parts of soot and hydrastis, will be found valuable. It may also be employed internally by mouth, or injection into the bladder or vagina, for *chronic mucous inflammation*. Soot is but little used at the present day.

FULIGOKALI.—A preparation called *Fuligokali* has been recommended in *scrofula*, *chronic rheumatism*, *rheumatic tumors*, and certain *herpetic affections*. It is made thus: To 2 or 3 parts of water add 50 parts of good, shining powdered soot, and 10 parts of caustic potash; boil the mixture for 1 hour, then dilute it when cold, and filter. The filtrate, when evaporated to dryness, yields a black powder, having a slightly alkaline taste, a burnt-like odor, and a ready solubility in water. It may be given 4 or 5 times a day, in doses of 2 to 3 grains. This substance should be kept in well-closed bottles (Deschamps). A stimulating discutient external application is made by triturating $\frac{1}{2}$ ounce of prepared lard with 8 or 16 grains of fuligokali (Gibert).

ANTHRAKOKALI.—A preparation occurring as a black powder, produced by boiling porphyzied coal with a strong solution of caustic potash, in an iron vessel. The mass is stirred, while cooling, until a powder results. This forms *simple anthrakokali*, but when sulphur in small amounts is added to the coal before it is put into the boiling potash solution, the resultant product is *sulphuretted anthrakokali*. These preparations were introduced by Dr. Polya, who applied them externally, and also administered them in doses of 1 to 1 $\frac{1}{2}$ grains, disguised in licorice-root powder. *Chronic rheumatic complaints*, including *rheumatic arthritic swellings*, as well as *scrofula*, and *skin diseases* of an herpetic character, were treated with it. An ointment (16 grains to 1 ounce of lard) was employed locally twice a day.

CARBONEI DISULPHIDUM (U. S. P.)—CARBON DISULPHIDE.

FORMULA: CS_2 . MOLECULAR WEIGHT: 75.93.

SYNONYMS: *Disulphide of carbon*, *Bisulphide of carbon*, *Carbonei bisulphidum* (U. S. P., 1880), *Alcohol sulfuris*.

Preparation and History.—Carbon forms two compounds with sulphur, a disulphide and a monosulphide; the former alone is of use in medicine or the arts. The latter is a more recent discovery, and is obtained by exposing the disulphide in sealed tubes to the sun's rays for several months (see Watts' *Dictionary*, 1888). Lampadius, in 1796, discovered carbon disulphide accidentally, while heating iron pyrites with charcoal, and, in 1802, Clement and Desormes obtained it by heating charcoal and sulphur. It is prepared upon a large scale by passing the vapor of sulphur over red-hot charcoal, in which case an impure carbon disulphide distills, and is collected in a cooled receiver beneath water. This crude article is always impure, containing dissolved sulphur and several sulphur compounds, which impart an offensive odor to the commercial article.

Purification.—Formerly, it was purified by repeated distillations from oil or fat, but, at present, the impure carbon disulphide is at first agitated with mercury until it ceases to blacken the bright surface of the metal, and then it is distilled from white wax; or it is allowed to remain a long time in contact with corrosive sublimate, or litharge, with frequent agitation, and is then distilled from bleached wax. M. Yvon, of Alfort, proposed the addition of copper turnings to the disulphide, in order to deodorize it, stating that it is not necessary to agitate

it; the disulphide soon loses its offensive odor, and gives out an ethereal odor, free from all unpleasantness.

Description.—The *U. S. P.* describes carbon disulphide as follows: "Carbon disulphide should be kept in well-stoppered bottles, or in tin cans, in a cool place, remote from lights or fire. A clear, colorless, highly refractive liquid, very diffusive, having a strong, characteristic, but not fetid odor, and a sharp, aromatic taste. Soluble in 385 parts of water at 15° C. (59° F.); very soluble in alcohol, ether, chloroform, fixed and volatile oils. Specific gravity, 1.268 to 1.269 at 15° C. (59° F.). Carbon disulphide vaporizes rapidly at the ordinary temperature, is highly inflammable, boils at 46° to 47° C. (114.8° to 116.6° F.), and, when ignited, burns with a blue flame, producing carbon and sulphur dioxide. It should not affect the color of blue litmus paper moistened with water (absence of sulphur dioxide. A portion evaporated spontaneously in a glass vessel should leave no residue (absence of dissolved sulphur). Lead acetate T.S. agitated with it should not be blackened (absence of hydrogen sulphide)"—(*U. S. P.*). Its flash ing point is stated differently by different authorities: 149° C. (300.2° F.), Frankland; 170° C. (338° F.), Braun; 160° C. (320° F.), Wagner's *Handbuch*, 1889. Its vapor, mixed with nitric oxide, burns with a bright-blue flame which is rich in actinic rays; and when mixed with oxygen or atmospheric air, the mixture explodes with great violence when inflamed. It evaporates so rapidly in the open air as to condense and congeal the moisture contained in the air on its surface; when evaporated in vacuo, a cold of -60° C. (-76° F.), may be obtained. It freely dissolves such bodies as essential oils, sulphur, phosphorus, iodine, bromine, camphor, gutta percha, caoutchouc, fats, wax, etc., and substances that are usually soluble in ether. It is insoluble in water, but soluble in alcohol, ether, and fats; its alcoholic solution becomes very readily changed, but if some essential oil of mint be added to it, it prevents its decomposition, and lessens any unpleasant odor. Under the action of the solar rays it assumes a yellow color. It is poisonous, and its vapor destroys small animals exposed to its action. When inhaled for some time, even in very small amount, it produces serious effects upon the nervous system. According to Zoller, meat may be preserved in an atmosphere which contains its vapor. It is used largely in various branches of the arts, as in india-rubber and woolen factories. Carbon disulphide has been employed in the process of the extraction of alkaloids to eliminate the fats, resins, chlorophyll, etc., present; to extract croton oil, bay oil, butter of cocoa, butter of nutmegs, oil of male-fern, oil of spruce, fir, etc.; to extract the fat from wool, bones, etc.; to manufacture soluble spices; to purify paraffin; to destroy certain noxious insects and animals; to preserve meats, fruits, etc.; also used to extract sulphur from certain minerals. It forms no solution with water, and advantage has been taken of this fact to determine the amount of moisture in commercial iodine. Berzelius found that it unites with metallic sulphides to form salts called *thiocarbonates*, or *sulphocarbonates*, in reality the salts of *thiocarbonic acid* (H_2CS_2), which is analogous to carbonic acid, the oxygen of which merely is replaced by sulphur. Carbon disulphide combines with *triethylphosphine* ($\text{P}[\text{C}_2\text{H}_5]_3$) to form a solid which crystallizes in beautiful red crystals ($\text{P}[\text{C}_2\text{H}_5]_3\text{CS}_2$). The formation of these crystals serves as a sensitive test for carbon disulphide. Another test not quite as sensitive consists in the formation of potassium xanthate by the combination of carbon disulphide with alcoholic potassa solution. Carbon disulphide, for medicinal use, should not possess a repulsive odor; the feter of the commercial article, as we have said, is owing to its impurity. It should likewise be neutral to litmus paper, and should not blacken mercury, nor precipitate a solution of plumbic acetate when agitated with it (Hoffman). As frequent contact with air occasions its deterioration, carbon disulphide, for medicinal use, should be placed in small, well-stoppered bottles, and kept in a cool place; it should not be handled nor poured out in the vicinity of flame.

Action, Medical Uses, and Dosage.—Disulphide of carbon was first used as an anæsthetic, in 1848, by M. Harald Taulow, of Christiania, Norway. Subsequently, Dr. Simpson, of Edinburg, confirmed the fact of its anæsthetic properties, and published his experiments to the profession (*Pharm. Jour.*, VII, p. 517). Its unpleasant odor, the disagreeable symptoms following its inhalation, as frequent pulsations, headache, vertigo, emesis, and annoying visions, together with

its brief anæsthetic influence, have proved objections to its coming into general use. Inhalation of air saturated with the vapor of the disulphide has been found injurious, as observed in the manufactories where it is employed for dissolving caoutchouc. The symptoms resulting from such inhalation have been described, by those physicians who have investigated this point, as follows: Headache, vertigo, wakefulness, impairment of the mental faculties, over-excitement of the nerves, neuralgic pains, cramps, bluntness of the senses of touch, sight, and hearing, impotency, derangements of the digestive functions, dyspnoea, palpitation, debility, emaciation, and occasionally, delirium. The period of excitation will be manifested in various ways, by vehement laughter, boisterous talking, rambling singing, weeping, etc. Mansfield, Wurtz, and others, have advised its internal use, in doses of 2 drops in milk, or in sweetened water, repeated every 2 hours, as an emmenagogue; it has also been proposed as a stimulant and sudorific in *rheumatic* and *gouty affections*, and in certain *cutaneous maladies*, but the uncertainty of its effects, and the serious symptoms apt to follow the ingestion of even a few drops, as intense burning sensation in the mouth and fauces, sickness at stomach, emesis, gastralgia, flatulency, and difficult micturition, will undoubtedly prevent its general use as an internal therapeutic agent. Dr. J. T. Whittaker has reported to have found its internal administration of considerable efficacy in the treatment of *carcinoma*, and especially that of the stomach; he administered it in doses of 2 drops in alcohol or almond oil, repeated every 2 or 4 hours. Although not curing the disease, it promptly mitigated the severe symptoms, improved the health and strength, and prolonged the life of his patients.

Its application, externally, has been found of great value in certain diseases. Its vapor, directed through a tube upon the eye, or upon the outer surface of the drum-membrane, for a few seconds, or until a glow of heat is experienced, acts as a stimulant and promotes absorption in the parts; employed in this manner, it has proven efficient in *deafness* due to deficient nerve power, lack of cerumen, in purulent discharges from the meatus auditorius, in tinnitus due to indurated cerumen with dryness of the canal, and in *eczema* of the ear; also in *chronic inflammation of the conjunctiva*, *ulceration of the cornea*, *lachrymal suppression*, *muscle*, *scleritis*, and in *scrofulous ophthalmia*, *phlyctenular formations*, etc. In *rheumatism*, *lumbago*, and other painful affections, benefit will often follow the application of the disulphide, on cotton or on a compress, over the painful parts; it should be allowed to remain in contact until a smarting sensation is produced. When it occasions pain, as will sometimes be the case, the vapor may be directed upon the part, instead, and be continued until the smarting sensation is complained of. If the disulphide be sprayed upon the part, allowing it to evaporate from time to time, before a renewal of the spray, in a few minutes local anæsthesia will result, pain will be relieved, and, if necessary, deep incisions may be made without any pain being felt. In this manner, it will likewise frequently be found useful in *gout*, *lupoid growths*, *glandular enlargements*, and *indolent tumors*. In many of the maladies just referred to, the efficacy of the remedy may be increased by the addition of iodine to the disulphide. Under the local anæsthesia that may be produced with the spray of carbon disulphide, such minor operations as the *evulsion of nails*, *opening of abscesses*, etc., may be painlessly performed. Topically applied it is also reputed a good remedy for various forms of *neuralgia*, particularly that associated with *locomotor ataxia* (applied upon the spine), and in neuralgic forms of *headache*, and in *toothache*.

In *atonic wounds* and *chronic ulcers*, its local application has proven very beneficial, as well as in *ulcerations* of a *scrofulous* or *syphilitic* character. A camel's hair pencil, or a pledget of lint, moistened with the fluid, is quickly and lightly passed over the surface of the wound or ulcer, which may then, if necessary, be immediately covered with a layer of finely pulverized subnitrate of bismuth or starch. This may be repeated once every 1, 2, or 3 days, according to the degree of inactivity of the ulcer. Its application is followed by intense pain, which, however, does not last longer than from 20 seconds to 3 or 4 minutes. Applied to *ulcers of the cervix uteri*, the pain continues but a few minutes, while that produced by other agents, as, for instance, acid nitrate of mercury, frequently continues for many hours. The pain gradually becomes less and less with each application, and as the cicatrizing process becomes confirmed, it diminishes and

disappears. Dr. Dorrington considers it by far the best local application known, for *indolent ulcers*. This fluid has also been applied in the form of a liniment, composed of 1 part of the disulphide to 4 parts of olive oil; also an ointment in *parasitic cutaneous diseases*, consisting of 1 part of the disulphide to 4 or 8 parts of lard. These should be kept in well-closed vessels.

Insects, frogs, lizards, dissected or not, and parts of animals, suspended from hooks, or deposited upon perforated shelves, may be preserved indefinitely in a perfectly air-tight vessel containing 5 drops of disulphide of carbon for every quart of air capacity. Strawberries, raspberries, cherries, beans, currants, cucumbers, peaches, radishes, etc., may be completely preserved in the same way, the only change noticeable being a fading of the color, and an exudation of juice from the berries. A short exposure to the air on removing these articles from the vessel, will render them fit to eat, and with a flavor the same as when fresh. The preservative powers of this fluid are chiefly due to its coagulation of albuminoids, and its lessening the quantity of free water in the article preserved in it. Seldom used internally. Dose, $\frac{1}{2}$ to 2 drops in alcohol, almond oil, milk, or sweetened or mint water.

CARBONEI TETRACHLORIDUM.—CARBON TETRACHLORIDE.

FORMULA: CCl_4 . MOLECULAR WEIGHT: 153.45.

SYNONYMS: *Carbonii tetrachloridum*, *Tetrachlor-methane*, *Carboneum chloratum*, *Chlorocarbon*.

History and Preparation.—Regnault discovered chlorocarbon, in 1839, but it did not become prominent until Simpson, of Edinburgh, suggested its use as an anæsthetic, in 1865. To prepare it, dried chlorine gas is made to pass through disulphide of carbon, then through a copper-wrapped tube of porcelain, filled with fragments of porcelain and maintained at a red heat, whereby a reaction ensues, in which sulphur chloride and carbon tetrachloride are produced, thus: $3\text{Cl}_2 + \text{CS}_2 = \text{S}_2\text{Cl}_2 + \text{CCl}_4$. Then, by the aid of ice, or other means of refrigeration, the vapors are condensed to a yellow-red liquid, treated to an excess of solution of caustic potash, or milk of lime, added slowly to decompose and dissolve the sulphur chloride. The chlorocarbon sinks to the bottom, and is distilled to effect its purification. It is also produced when chloroform, or marsh gas (CH_4), are acted upon by chlorine in direct sunlight, the result being chlorocarbon and hydrochloric acid.

Description.—Chlorocarbon (CCl_4) is a chlorinated derivative of methane or marsh gas. It is sometimes alluded to under the old name, bichloride of carbon, given it under the old chemical notation. It is a thin, colorless, oily fluid, of an agreeably fragrant odor, soluble in ether and alcohol, but not in water. Its density is 1.599; its boiling point 77°C . (170.6°F .). If carbon disulphide be present it may be removed by solution of caustic potash, which does not decompose the chlorocarbon at ordinary temperature.

Action and Medical Uses.—This agent is pleasant in odor, and, when inhaled, first produces a cooling sensation in the fauces, followed by a general glow of warmth throughout the body. If its administration be stopped short of anæsthesia, a prolonged sense of calm is experienced, followed by a refreshing sleep. Anæsthesia is quickly produced by it, but complete consciousness returns very shortly after ceasing inhalation. It was experimented with by Drs. Sansom and Harley, in 1864, and introduced into general medicine, as an efficient anæsthetic, by Simpson, of Edinburgh, in 1865. Owing to its depressing action upon the heart, it has been practically discarded, being considered a dangerous agent, even when skillfully handled.

Related Compound.—CARBON TRICHLORIDE, or *Hexachlorethane* (C_2Cl_6). When in direct sunlight dry chlorine gas is made to pass into either ethylene chloride ($\text{C}_2\text{H}_4\text{Cl}_2$), or ethyl chloride ($\text{C}_2\text{H}_5\text{Cl}$), until the fluid solidifies, a crystalline mass of carbon trichloride forms, which may be purified by recrystallizing with alcohol. It forms in white or colorless prisms of the rhombic system, is almost tasteless, has an aromatic and camphor-like odor, and is brittle and easily reduced to a powder. Alcohol, fats, essential oils, and ether easily dissolve it, but it is not soluble in water. Its density is 2.0. At the temperature of the air it slowly volatilizes; at 160°C . (320°F .) it fuses; and at 182°C . (359.6°F .) it forms a crystalline sublimate. Burned with alcohol it exhibits a red flame.

CARDAMOMUM (U. S. P.)—CARDAMOM.

"The fruit of *Elettaria repens* (Sonnérat), Baillon"—(U. S. P.). (*Elettaria Cardamomum*, Maton; *Alpinia Cardamomum*, Roxburgh; *Anomum repens*, Sonnérat; *Anomum Cardamomum*, White; *Renalmia Cardamomum*, Roscoe; *Matonia Cardamomum*, Smith).

Nat. Ord.—Scitamineæ.

COMMON NAMES AND SYNONYMS: *Cardamom seeds*, *Malabar cardamoms*; *Cardamomum Malabaricum*, *Cardamomum minus*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 267.

Botanical Source.—*Elettaria repens* has a knobbed, perennial rhizome, with many fleshy radicles. The stems are numerous, erect, simple, jointed, enveloped in the spongy sheaths of the leaves, and about 4 or 6 feet high. The leaves are bifarious, subsessile on their sheaths, lanceolate, fine-pointed, somewhat villous above, sericeous underneath, entire, 1 or 2 feet long, and nearly $\frac{1}{2}$ foot broad; the sheaths are slightly villous, with a rounded ligula rising above the mouth. There are from 3 to 5 scapes proceeding from the base of the stem, which are from 1 to 2 feet long, lying upon the ground, flexuous and jointed; the branches or racemes are alternate, 1 from each joint of the scape, sub-erect, and 2 or 3 inches long. The solitary bracts are oblong, smooth, membranous, striated, sheathing, and but 1 at each joint of the scape. The flowers are alternate, short-stalked, solitary at each joint of the racemes, opening in succession as the racemes lengthen. The calyx is monophyllous, funnel-shaped, 3-toothed at the mouth, about $\frac{2}{3}$ of an inch long, striated with fine veins, and permanent. The tube of the corolla is slender, as long as the calyx; limb double, exterior of 3 oblong, concave, nearly equal, pale, greenish-white divisions; inner lip obovate, much longer than the exterior divisions, somewhat curled at the edge, with the apex slightly 3-lobed, and marked chiefly in the center with purple-violet stripes. Filament short and erect; anther double and emarginate. Ovary oval and smooth. Style slender. Stigma funnel-shaped. Capsule oval, somewhat 3-sided, size of a small nutmeg, 3-celled, and 3-valved; seeds pale-brown, coriaceous, and numerous (L.).

History and Description.—*Elettaria repens* inhabits the mountainous parts of the coast of Malabar, where it grows both cultivated and uncultivated, the cultivated plants generally yielding the commercial cardamoms. (For account of culture, see *Pharmacographia*). The fruit, which is the official part, is not obtained until the shrub has reached its utmost height, which requires 4 years. The *Pharmacopœia* describes cardamoms as "ovoid or oblong, from 10 to 15 Mm. ($\frac{3}{8}$ to $\frac{1}{2}$ inch) long, obtusely triangular, rounded at the base, beaked, longitudinally striate; of a pale-buff color, 3-celled, with a thin, leathery, nearly tasteless pericarp, and a central placenta. The seeds are about 4 Mm. ($\frac{1}{4}$ inch) long, reddish-brown, angular, rugose, depressed at the hilum, surrounded by a thin, membranous arillus, and have an agreeable odor and a pungent, aromatic taste"—(U. S. P.). They contain about 75 per cent of the seeds which contain the active properties, while their covering, which has very little smell or taste, should be rejected; the aromatic, camphoraceous flavor of the seeds is soon lost when deprived of the capsules covering them.

The length of the commercial cardamoms varies, and on this account dealers have denominated, *longs*, *mediums* (*short-longs*), and *shorts*. The *Malabar*, as well as *Aleppi* fruits, constitute the ovoid varieties, while the longer and more acuminate seeds are the *Madras cardamoms*.

Chemical Composition.—Water or alcohol takes up the virtues of the seeds, which Trommsdorff found, in 1834, to be due to a colorless, strongly fragrant, volatile oil, of sp. gr. 0.943, which is very soluble in alcohol, ether, oils, and acetic acid; insoluble in potash-lye. It has a hot, camphoraceous, bitter taste, and exists to the extent of 5 per cent and less in Malabar cardamoms (Flückiger, 1891). By keeping, it becomes yellow, viscid, and loses its peculiar taste and smell. It consists chiefly of terpene bodies, whose constitution is $C_{10}H_{16}$. Crystalline *terpin hydrate* ($C_{10}H_{16} \cdot [H_2O]_3$) was obtained by Dumas and Péligot from oil that had been kept for a considerable length of time. The seeds contain also about 10 per cent of fatty oil, and the ash contains a marked amount of manganese, some starch, gum-like extractive, coloring material, and potassium salts—(*Pharmacographia*).

Action, Medical Uses, and Dosage.—Cardamom seeds are very warm, grateful, pungent and aromatic, and form an agreeable addition to bitter infusions, and other medicinal compounds. They are chiefly employed as a carminative in flatulency, and to flavor syrups, tinctures, etc. Dose of the powder, from 10 grains to 2 drachms; infusion (bruised seeds, $\mathfrak{z}\text{ij}$ to boiling water, Ossi), a wineglassful. As the powder rapidly loses its aromatic property, the seeds should be pulverized from time to time, as they are required for present employment.

Other Cardamoms and Related Seeds.—The following cardamoms are used in Oriental countries, but are not often seen in American commerce:

I. **CEYLON CARDAMOM.**—This variety is variously known as *Long*, *large*, and *wild cardamom*. In the East it is incorrectly termed *Grains of Paradise*. It is the product of a Ceylon plant, the *Elettaria major*, Smith, now regarded merely as a variety of *Elettaria repens*. The fruits are from 1 to 2 inches long, lance-oblong, have 3 flat sides, are sometimes arched, and of a deep gray-brown color. They are terminated with a prolonged apex. They contain more seeds than the Malabar cardamom, and are larger, and differ in taste and odor, being less agreeable. Its properties are similar to those of cardamom, having essentially the same chemical components, besides, according to Flüchiger, a dextrogyrate body, apparently like ordinary camphor.

II. **ROUND CARDAMOM.**—Known also as *Cluster cardamoms*. This variety is the fruit of *Amomum Cardamomum*, Linné, growing in the East Indies and in Siam. They grow in compact clusters, are globular or ovate, about the size of a common cherry, and have a somewhat hairy, buff-colored pericarp. The seeds resemble those of Malabar cardamom, but have a more strongly aromatic, camphoraceous taste. They are consumed considerably in South Europe.

III. **XANTHOID CARDAMOM.**—This is the fruit of *Amomum xanthioides*, Wallich, growing in Siam and Tennasserim, and is variously known in English markets as *Cardamom seeds*, *Bastard* or *Wild cardamom of Siam*. They have received their specific name from the fact that the pericarp is thickly covered with fleshy, spinous projections, as in the species of *Xanthium*. The seeds only appear in market, and resemble those of cardamom, being, perhaps, more finely wrinkled, but differ in flavor.

IV. **NEPAL CARDAMOM.**—This corresponds almost exactly with the following variety, except that it terminates in a tube-like calyx, of at least the length of the fruit itself, and differs also in being sometimes borne on a short stalk (*Pharmacographia*). It is produced by an undetermined species of *Amomum*.

V. **BENGAL CARDAMOM.**—This variety is known as *Morung elachi*, *Buro elachi*, and *Winged Bengal cardamom*. The fruit has a brown color, is about an inch in length, of ovoid or sub-obconic form, rounded at the lower end, and has 9 jagged, ridge-like wings near the distal extremity, the latter terminating in a truncated, nipple-like projection. It contains from 60 to 80 highly aromatic and camphoraceous seeds, imbedded in a viscid, sweet pulp. The wings are more readily seen if the seeds be soaked in water. Bengal cardamom is the fruit of *Amomum subulatum*, Roxburgh.

VI. **JAVA CARDAMOM.**—A Java plant, the *Amomum maximum*, Roxburgh, furnishes this variety. They are borne in a globe-like group, each scape having from 30 to 40 fruits. They are conical, or ovoid, stalked, $1\frac{1}{2}$ inches in length, by 1 inch in breadth (when fresh), have 9 or 10 conspicuous wings passing the whole length of the fruit, and coarsely dentated, except in the lowermost portions. They are faintly aromatic, and their essential oil is of an inferior quality. They have an edible pulp which is prized by the Javanese.

VII. **KORARIMA CARDAMOM.**—True cardamomum majus, Korarima, Heil, Gurhji spice, Habhal-habashi, Heel habashee. Conical, perforated fruits, resembling inverted figs, and having aromatic, angular seeds resembling in taste and odor those of Malabar cardamoms. They are perforated by the natives so that they may be strung to dry, and in this manner are occasionally used by the Arabs for rosaries. The plant which produces them inhabits eastern Africa, and has not been described by botanists, but Pereira proposed for it the name *Amomum Korarima*.

VIII. **CHINESE CARDAMOM**, or *Rouma Chinese cardamom*.—This is the fruit of the *Amomum globosum*, Loureiro, and is characterized chiefly by having a rounded side.

IX. **MADAGASCAR CARDAMOM.**—This fruit is believed to be derived from the *Amomum angustifolium*, Sonnerat. It is ovate, striated, has one flattened side, is pointed, and presents at the base a broad scar, circular in outline, and surrounded by a raised, wrinkled, and notched border. The taste and flavor resemble those of the official variety.

GRANA PARADISI.—*Grains of Paradise*, *Guinea grains*, *Melegueta pepper*, *Piper melegueta*. At least 7 species of fruits have at times received the name of *grains of Paradise*. That now recognized as the true variety is the fruit of *Amomum Melegueta*, Roscoe, a reed-like plant growing widely distributed along the tropical portions of western Africa. The botanical source of this plant has given rise to much confusion, but as Mr. Daniel Hanbury raised well-developed specimens (from the commercial seeds), which bloomed and bore the perfect fruit, the botanical origin above given seems clear from doubt. It is stated that there are two grades or varieties of seed in market, according to some authorities, both being the fruit of the same plant, while others believe one variety to be derived from *Amomum granum paradisi*, Afzelius, said to be a Sierra Leone plant. It is the smaller of the two kinds. The commercial *grains of Paradise* resemble cardamom seeds both in appearance and size, but do not possess a rugose surface. The seeds are variable in shape, but generally are $\frac{1}{4}$ inch in diameter. They are somewhat rounded, or blunt-angular, hard, shining, and of a red-brown color. The hilum is

not so deeply colored, and that sort referred to as *melegueta pepper* or *Guinea grains*, has an elevated, tufted, beak-like hilum, while the smaller kinds present a broad, depressed hilum. Both are faintly aromatic in odor, but have a very hot, peppery taste. Under the name of "*grains*" they were used as pepper, and as an ingredient of a spiced wine—*hippocras*—containing also ginger and cinnamon, they were quite popular in the middle ages. Grains of Paradise contains a volatile oil having a fragrant, but non-acrid taste. It is neutral, yellowish in color, and possesses the agreeable odor of the seeds. It dissolves sparingly in alcohol, but is soluble in carbon disulphide. Iodine is dissolved by it. Its formula, according to Flückiger, is $C_{20}H_{32}O$, and density 0.825 at 15.5° C. (60° F.). The ash is colored greenish through the manganese present. Gum, tannin, starch, and a viscid, brown resin, soluble in acetic acid, have also been obtained from the seeds. Thresh (1884) announced the discovery of the active constituent as a viscid, pale-yellow fluid, without odor, but having a pungent taste, not so peppery, however, as capsaicin. Grains of Paradise are employed almost wholly in giving fictitious strength to liquors, and in compounding certain veterinary powders.

CARDUUS MARIANUS.—ST. MARY'S THISTLE.

The ripe seeds of *Carduus marianus*, Linné (*Cnicus marianus*, *Silybum marianum*, Gärtner).

Nat. Ord.—Compositæ.

COMMON NAMES: *Mary thistle*, *Milk thistle*, *St. Mary's thistle*.

Botanical Source.—Mary thistle is an annual, or biennial plant, glabrous, or but slightly wooly, growing to a height of 2 or 3 feet, and branching but little. Its leaves, which are shining and smooth above, are marked with white veins; the lower leaves are deeply pinnatifid, the lobes being broad and very prickly; the upper ones clasp the stem by prickly auricles, and are scarcely decurrent. The large, drooping flower-heads, with purple florets, are solitary and terminal upon the branches. The involucre bracts are very broad at the base and have a stiff, spreading leaf-like appendage, terminating in a long spine, and bordered at its base with prickles. The fruit is an achenium. The pappus hairs are simple.

FIG. 57.

Carduus marianus.

History and Description.—Mary thistle is indigenous to southern Europe. The part used in medicine is the fruit known as *Fructus silybi*, or *Semen cardui marie*. The achenia are from $\frac{1}{8}$ to $\frac{1}{4}$ of an inch long, obovate, smooth, shining, and pale-brown in color, with striæ of a black, or blackish hue. At the apex they are oblique and have a marginal crown of a yellowish color, from the center of which the style-base projects. They have no odor, but a mucilaginous and oleaginous, as well as bitterish, taste. They yield their virtues to diluted alcohol. The Homœopathic mother tincture is prepared by covering the whole ripe seeds (1 part by weight) with diluted alcohol (2 parts), and letting stand in a dark, cool place in a well-stoppered bottle for 8 days, shaking twice a day. It is then decanted, strained, and filtered. The introduction of this medicine into Eclectic therapeutics is due chiefly to Prof. H. T. Webster, M. D. (*Dynam. Therap.*), and to Prof. Finley Ellingwood, M. D. (*Ecl. Annual*, Vol. I).

Action, Medical Uses, and Dosage.—*Carduus marianus* is an old remedy, which had nearly passed out of use and has more recently been revived. Rade-macher valued the seeds in *hemorrhages* associated with *splenic* or *hepatic disorders*. That it influences the parts supplied by the coeliac axis, particularly the distribution of the hepatic and splenic arteries, especially the latter, seems well established. *Congestive conditions of the splenic circulation* are those most benefited by it. To a lesser extent, the whole venous apparatus is influenced by this drug, giving power to the veins, and preventing *varicose*s and other dilatations. But little effect, however, is observed upon the hemorrhoidal circulation, as piles do not seem to be directly benefited by it. Dull, aching, splenic pain passing up under the left scapula, and associated with pronounced general debility and despondency is the indication for its use. It controls splenic pain even where no enlargement can be detected, and it is the remedy for *hypertrophy of the spleen* when non-malarial in character. *Congestion of the liver, spleen and kidneys* is relieved by its use. *Bilious states*, with stitches in the side and pain in the abdomen, hard and tender right hypochondrium, *gall stones*, *jaundice*, *hepatic pain and swelling*,

vomiting of pregnancy, and leucocythemia, are conditions in which it is reported useful. *Amenorrhœa*, with wrong of the portal circulation, *melæna*, *hemoptysis*, and *uterine hemorrhage*, have all been successfully treated with it. *Hematuria*, with weight and pain in the pelvis, has been promptly met by 25-drop doses in water, twice a day. *Painful dysuria*, from *urethral caruncle*, and *pelvic congestion* have also been quickly relieved by it. A strong tincture (seed, 3viii to alcohol Oj), or the homœopathic mother tincture, in doses of from 1 to 20 drops.

Specific Indications and Uses.—Splenic, hepatic and renal congestion, face sallow, appetite capricious; nervous irritability; despondency; physical debility; pain in either hypochondriæ; pelvic tension and weight; congestion of the parts supplied by the coeliac axis; and non-malarial splenic hypertrophy.

CARICA PAPAYA.—PAPAW.

The juice of the fruit, and *Papain*, the digestive ferment, obtained from *Carica Papaya*, Linné (*Papaya vulgaris*, De Candolle).

Nat. Ord.—Passifloraceæ.

COMMON NAMES: *Papaw*, *Pawpaw*, *Mamæiro*.

ILLUSTRATIONS: *Botanical Register*, Plate 459; *Botanical Magazine*, 2898 and 2899.

Botanical Source.—*Carica Papaya* is a tree indigenous to South America, where it is met with in its wild condition, as well as under cultivation, and varies in height, according to its wild or cultivated state, from 5 to 30 feet, and is about 1 foot in diameter (Rees' *Cyclopædia*). The trunk or stem is simple, erect, without branches, and gradually tapers from the base to the summit, where it terminates in a cluster of leaves, after the manner of a palm. Its entire length is thickly covered with the scars of the fallen leaves. The leaves are large, alternate, close together, palmately divided into from 5 to 7 irregularly cut lobes, and are borne on leaf-stalks 1 or 2 feet in length, and which are peltately attached. The flowers are dioecious, rarely monœcious, and are grouped at the top of the trunk; the male flowers are borne on long peduncled racemes; the female flowers are solitary and axillary on short stalks, and consist of a small, 5-parted calyx, 5 twisted, pale-yellow petals and a large ovary, bearing 5 dilated, subsessile stigmas. The ovary is globular, 1-celled, and contains numerous ovules attached to 5 parietal placentæ. As the ovary enlarges and develops, the leaves gradually fall off, and the fruit, when matured, appears suspended to the highest part of the smooth trunk (L.).

History.—The *Carica* constitute a family of phanerogamous plants, which grow in the East Indies and in South America, either in a natural state or cultivated. The following species have properties similar to those of *C. Papaya*: *Carica spinosa*, Well, a native of the provinces of Pernambuco, Rio de Janeiro, etc.; and *Carica dodecaphylla*, or *jaracatia*, a tree of high stature, with a trunk furnished with spines. When incised, this last gives a milky juice. Its fruit is smaller and longer than that of the *Carica Papaya*.

The *Carica Papaya* is cultivated throughout the greater part of Brazil, and its fruit bears some resemblance to that of the Cucurbitaceæ, especially to the genus *Cucumis*. The fruit, when ripe, is yellow, irregularly ovoid, with 5 rib-like projections; it is pulpy, enclosing numerous blackish seeds, and has a rather agreeable, sweetish taste. The root is said to have an odor resembling that of rotten cabbage. In Brazil, the common name of the plant is *mamæiro*, and the fruit is called *mamao*. The juice or milk proceeding from the bark or fruit is the part that has attracted attention. In 1850, Hoeferk stated that the juice was milky, bitter, and possessed the property of an irritant poison, and that, when mixed with water, it was used to soften tough meats, by macerating them in the liquid. A. Pinto, A. Camara, and Martius have made nearly the same statements; and Pinto also remarks that it is used to render the skin of the hands soft, and to remove freckles from the face. In 1875, Dr. Roy, an English physician, instituted some experiments with the milky juice, and found that it had the property of softening and dissolving meats; a microscopic examination of the meats thus dissolved showed a complete disintegration of the muscular fibers, the fasciculi being dissociated, and the ultimate fasciculi in a fair way for separation. The

entire fluid mass was swarming with vibriones. Other investigators have arrived at the same results.

Chemical Composition.—The milk of *mameiro*, whether from the bark or from the fruit, is so small in amount that a sufficient supply for instituting a regular chemical analysis can not be procured; the greatest quantity that has been obtained from a large number of trees and fruit is in all about 1 fluid ounce. Another circumstance which antagonizes analysis and interferes with investigation of its physiological and therapeutical effects, is the extraordinary rapidity with which it enters into fermentation, and which commences a few seconds after its extraction. The seeds of the fruit contain a resinous acid, which is probably their active principle. Dr. T. Peckolt obtained it by treating the fresh seeds with boiling alcohol and hydrate of lime, and then separating it by means of hydrochloric acid. It forms a yellowish powder, possessing a pungent taste.

The active principle or ferment of *Carica Papaya*, a true vegetable pepsin, formerly termed *caricine*, is now known as *papain*, or *papayotin*. Mauriac obtained it (from the leaves) by extracting the juice from those recently gathered and filtering it. To the turbid and yellowish-green filtrate, double its volume of absolute alcohol was added, and, gradually, a flocculent precipitate of *papain* formed upon the filter, slightly greenish and amorphous. This may be purified by new solutions and precipitations, and then carefully drying at a temperature not to exceed 40° C. (104° F.). *Papain* is obtained from the leaves in the proportion of 4 parts to 100. It is insoluble in alcohol, and perfectly soluble in distilled water. Nitric and hydrochloric acids, bicarbonate of sodium, or of potassium, and caustic potash have no action upon it. It may be employed as a solvent of albuminoid materials in certain forms of dyspepsia, and as an anthelmintic.

PAPAIN is an amorphous powder, white, or yellowish-white, practically odorless when pure, and has a feeble taste, almost imperceptible, yet faintly suggestive of pepsin. Its composition, further than the fact that it contains 10.6 per cent of nitrogen, has not yet been determined. It dissolves in water and glycerin, the aqueous solution becoming turbid when boiled. Its peptonizing powers are said to be greater than those of pepsin, 0.1 part being capable of dissolving from 100 to 200 parts of moist blood fibrin (see Wurtz, *Amer. Jour. Pharm.*, 1881). It acts under all conditions, whether in neutral, acid, or alkaline media, and is most energetic in the presence of a small amount of fluid. A considerable portion of the *papain* on the market is said to be practically inert.

In 1890, Dr. Greshoff, in Batavia (Java), discovered a new alkaloid in the leaves of *Carica Papaya*, which he named *carpaine*. It exists to the extent of 0.25 per cent in the dried and young leaves, but only in an amount of 0.07 per cent in old leaves; has a bitter taste, and a melting point of 121° C. (249.8° F.). The formula is $C_{11}H_{12}NO_3$, and its physiological properties were investigated by Dr. von Oefele, who found that, with the exception of the caffeine group, *carpaine* was the only digitalis substitute which, by subcutaneous injection, did not cause local irritation or abscesses, while internal doses of 0.025 Gm. per day did not show any advantage over digitalis (*Amer. Jour. Pharm.*, 1893).

Action, Medical Uses, and Dosage.—Without entering into a description of the varied experiments that have been made with the milk of *carica*, and concerning which an excellent account is given by Dr. Moncorvo, of Rio de Janeiro, in his translation of an article in the Portuguese language, entitled: "Note on the Physiological and Therapeutical Action of *Carica Papaya*," by Dr. E. Mauriac, we will simply refer to the conclusions drawn therefrom. This substance exerts a real dissolving or digestive action upon nitrogenized substances; this action is likewise obtained with it in aqueous solution, while its solution in alcohol appears to render it wholly inert. It has no action upon feculent substances. Applied upon the skin, it renders it softer and more smooth, and appears to destroy the projections formed at certain points by a greater or less thickening of the epidermis. Upon the skin deprived of its epidermis, and upon the subcutaneous cellular tissues, it has an extremely irritating action, provoking intense inflammation; and, in addition, the formation of abscesses, rapidly followed by a putrid infection when 30 grains were hypodermatically injected, these symptoms being preceded by severe pain, moaning, and great difficulty of motion. Upon the digestive mucous membrane it acts as a caustic and corrosive substance, its effects

being rapid, violent, deep-seated, and occasioning energetic purgation. According to Desjardins, boiling removes these corrosive effects, and it then proves the most active vermifuge of the *Materia Medica*, in doses of 1 or 2 drachms, mixed with an equal quantity of castor-oil, a single dose being sufficient to cause the expulsion of an astonishing number of the *lumbricoids*. The seeds possess an identical property, and will probably be found preferable for administration. It is likewise said to cause the destruction and expulsion of the *tapeworm*. Various preparations of carica are reputed abortifacient and galactagogue.

The chief property of the milk of the carica is its action upon food, similar to that of pepsin, exercising, like this latter article, a digestive influence upon albuminoid substances. But the difficulty of procuring and preserving a sufficient amount of it for therapeutical use, together with its deeply irritating action, will prevent it from coming into use as a remedy for *dyspepsia* or *gastric affections*. To overcome these obstacles, Dr. Mauriac instituted a series of experiments with the leaves of the tree, and found that a concentrated decoction of them exerted upon albuminoid substances an action analogous to that of the milky juice of the tree and of the green fruit, without any appreciable irritation of the gastric mucous membrane. This decoction must be administered in small doses. Dr. Mauriac and others, however, prefer papain, the action of which does not appear to be interfered with by an acid or neutral condition of the stomach, and which, being more energetic than pepsin, must be given in smaller doses, and in aqueous solution. Papain has been used in *atonic* and *fermentative dyspepsia*, with painful acid eructations, flatulence, and constipation.

The softening and disintegrating qualities of papain (generally in alkaline combination, as with borax or potassium carbonate), have been taken advantage of in the treatment of warts, corns, sinuses, and chronic forms of scaly eczema, cutaneous tubercles, and other hardness of the skin, produced by irritation, etc., and injected into indolent glandular tumors to promote their absorption. *Epithelioma* has been similarly treated, but this painful procedure is not to be commended. Glossal fissures and ulcerations, and particularly syphilitic ulcerations of the throat, mouth, and tongue, are asserted to have yielded to alkaline solutions of papain. Papain, in 5 per cent solution, when pure, is credited with the power to dissolve the false membranes of diphtheria and membranous croup. This can be accomplished only when the solution can be brought into contact with the membrane by means of a brush or spray. It must be frequently applied as it has no power to prevent a subsequent formation of the membranous exudate. A 5 per cent solution of papain, with sodium bicarbonate, 5 grains, warmed and instilled into the ear in quantities of 10 or 15 drops, and allowed to remain 1 hour, has given good results in chronic suppurative inflammation of the middle ear, with scanty, offensive discharge; the 5 per cent solution alone has been employed to remove hardened secretions from the auditory canal. The dose of papain is from 1 to 5 grains.

CAROTA.—WILD CARROT.

The root and fruit of *Daucus Carota*, Linné.

Nat. Ord.—Umbelliferae.

COMMON NAME: Wild carrot.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 135.

Botanical Source.—Wild carrot is a biennial herb, with a slender, yellowish, aromatic, spindle-shaped and sweetish root. Its stems are 2 or 3 feet high, round, branched, erect, furrowed, leafy, hairy, or bristly. The leaves are alternate, on broad, concave, ribbed footstalks, bipinnate, cut, narrow, acute, and distantly hairy; the leaflets are linear and acute. The flowers are small, white or cream-colored, except the one central, neutral flower, which is blood-red. The umbels terminate the long, leafless branches, and are solitary, large, dense, concave, and many-rayed. The general involucre is pinnatifid, slender, and large, though not so long as the umbel; the partial involucre is undivided, or partly 3-cleft, and membranous at the edges; the petals, 5 in number, are obovate and emarginate, with an inflected point. Fruit small, oval, somewhat compressed, and pale dull-brown; the half-fruits or mericarps with the 5 primary ridges, filiform and bristly,

the 3 middle ones at the back, the lateral on the plane of the commissure; the 4 secondary equal, more prominent, winged, and split into a single row of spines. The vittæ are solitary in the channels below the secondary ridges (L.—W.—G.).

History.—Wild carrot is indigenous to Europe, and is extensively naturalized in this country, growing in old fields and by roadsides, flowering from June to September. By cultivation it becomes somewhat changed, as in the garden carrot. The root of the wild variety, and the seeds of both kinds are employed.

Description.—**CARROT SEEDS.** The seeds or mericarps are oval, with plano-convex surfaces, slightly ciliated, and marked with 5 ridges, from 1 to $1\frac{1}{2}$ lines long, of an agreeable, aromatic smell, and a moderately pungent, bitter taste (*Ed.*). Their medicinal properties are owing to a volatile oil, which is colorless, or slightly tinged with yellow, and which may be procured by distilling them with water. They yield their virtues by infusion, to water, at 100°C . (212°F .); boiling dissipates them. No particular analysis has been made of them.

CARROT ROOT.—The root is fusiform, slender, yellowish-white, occasionally branched, rather woody, possessing a peculiar aromatic odor, and an unpleasant, bitterish taste, with some acrimony. The root of the garden carrot is fusiform, from 9 to 12 inches in length, white, orange, yellow, or reddish-colored, transversely wrinkled, with scattered radicles, having a reticulated bark or fleshy parenchyma, and a round or angularly radiated medulla; they are quite thick, have an agreeable, peculiar odor and a rather pleasant, saccharo-mucilaginous taste.

Chemical Composition.—According to Wackenroder, the expressed juice of carrot root contains fixed oil, with some volatile oil, a coloring matter termed by him *carotin*, uncrystallizable sugar, with some starch and malic acid, mannit, albumen, and ashes composed of salts of aluminum, calcium, and iron. It also contains *pectose*, a substance insoluble in water, alcohol, or ether, which gives the hardness to green fruits, and which may be converted into *pectin*. The volatile oil is of sp. gr. 0.8863 at 12.2°C . (54°F .), is very soluble in alcohol or ether, less so in water, is colorless, and has the odor and strong taste of carrots. *Carotin* ($\text{C}_{40}\text{H}_{56}\text{O}$, according to Husemann), is a ruby-red, crystalline, tasteless, odorless, neutral substance, heavier than water, fusible, combustible, soluble in fixed and volatile oils, benzol, and carbon disulphide, slightly so in alcohol, chloroform, and ether, insoluble in water; and its solutions are not decolorized by solar light. The solution in carbon disulphide is blood-red, and yields *carotin* as a precipitate upon the addition of alcohol. It undergoes a complete change when exposed to light, becoming colorless and amorphous, and much less soluble in carbon disulphide, but easily soluble in alcohol and ether (Husemann).

Another body, in the juice of the root, was investigated by A. Husemann, in 1860, named by him *hydrocarotin* ($\text{C}_{40}\text{H}_{56}\text{O}$), which is the same substance as that found by Brimmer in angelica root. From hot alcohol it crystallizes upon cooling in silky, colorless crystals, devoid of taste. Arnaud also obtained a body related to cholesterin, differing but little from the animal product of that name, but agreeing with the phytosterin obtained from the calabar bean (*Comptes Rendus*, cii, 1319). After repeated alcoholic purification it was obtained, combined with a molecule of water, in foliaceous condition.

Pectin or *vegetable jelly* is found universally scattered over the vegetable kingdom, being in considerable quantity in many fruits, roots, etc. It may be obtained from the juice of all fruits by (1) the cautious addition of oxalic acid to throw down their calcium salts; (2) then adding a concentrated solution of tannin so long as a precipitate occurs, of coagulated albumen; (3) separating the albumen by filtration, and then adding alcohol to the clear liquid, and leaving the solution for a couple of days to spontaneous evaporation, when the pectin is deposited in a gelatinous coagulum; to obtain it in purity, subject it to gradual pressure, and wash it with weak alcohol. It is translucent like isinglass, swells in 100 parts of cold water, forming a mass like starch, but not colored blue by iodine; boiling water has less action upon it than cold. It is insoluble in alcohol or ether, and has no action on polarized light. The least trace of a fixed alkali instantly converts it into pectic acid, forming a pectate of the alkali, the addition of another acid decomposes it, and sets the pectic acid free. *Pectic acid* has the form of a transparent and colorless jelly, with a perceptible acid taste, reddens litmus, and forms salts with alkalies (T.).

Action, Medical Uses, and Dosage.—Both the root and seeds are mildly stimulant and diuretic. Used in infusion with much success, in *dropsy*, *chronic nephritic affections*, and *gravel*. Also as a carminative, and to relieve *strangury* from cantharides. Carrot is said to possess emmenagogue properties, and the juice is reputed to relieve *pruritis*, accompanying some forms of skin disease. Externally, scraped or grated, it forms an excellent application as a poultice to *phagedenic*, *cancerous*, *malignant*, and *indolent ulcers*—relieving the pain, correcting the fetor, lessening the discharge, and altering the morbid condition of the parts. Dose of the infusion (3j to water Oj), from 2 to 4 fluid ounces, 3 or 4 times daily; of the powdered seeds, 20 to 60 grains.

CARTHAMUS.—DYER'S SAFFRON.

The florets of *Carthamus tinctorius*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES AND SYNONYM: *Safflower*, *Bastard saffron*, *Dyer's saffron*, *African saffron*, *False saffron*, *American saffron*; *Flores carthami*.

Botanical Source.—*Carthamus tinctorius* is an annual plant, with a smooth stem, growing from 1 to 2 feet high, striate, and branching at the top. The leaves are alternate, ovate-lanceolate, sessile, spinose-denticulate, subamplexicaul, smooth and shining. The flowers are numerous, long, slender, orange-colored, and borne in large, terminal, discoid heads. The florets are tubular; the corolla infundibuliform and 5-cleft (W.).

Carthamus tinctorius.

History and Description.—This plant is cultivated in this country and Europe, though inhabiting Egypt and the countries surrounding the Mediterranean Sea. The orange-red florets are the medicinal parts, and are generally met with in commerce in laminated masses, with the yellow filaments accompanying. Their odor is peculiar and aromatic, and the taste slightly bitter. Dyer's saffron is sometimes used to adulterate genuine saffron, but may be detected by the cannular form of the flowers, the reddish-yellow color of their stamens and pistils, and the absence of the white ends belonging to the true saffron. The cultivated safflower in this country is usually sold unpressed, as American saffron.

Chemical Composition.—Safflower contains 2 coloring matters: the first, which is soluble in water, is yellow (called *Safflor yellow*); the other has a beautiful red color, greenish in reflected light, is insoluble in water, fixed and volatile oils, ether, and in diluted acids, is slightly soluble in alcohol, but readily soluble in alkaline solutions, in which, however, it readily decomposes, with discharge of the color, and is termed *carthamin*, or *carthamic acid* ($C_{14}H_{16}O_7$). Its acid properties are feeble. Dried and mixed with French chalk, it constitutes rouge, which is used as a cosmetic. *Carthamin* is the valuable dye constituent. Both *carthamin* and *safflor yellow* were investigated particularly by Schlieper. The former exists in small amount (0.3 to 0.6 per cent); the latter is abundant (25 to 30 per cent).

Action, Medical Uses, and Dosage.—Dyer's saffron, when the warm infusion is used, is said to restore the menstrual discharge which has been recently suppressed by cold; also when taken largely, to produce an action on the bowels. The warm infusion is often employed as a diaphoretic in domestic practice among children and infants in *measles*, *scarlet fever*, and other *eruptive maladies*. It may be given tolerably freely. The infusion may be made by infusing 1 or 2 drachms of the flowers in $\frac{1}{2}$ pint of boiling water. The seeds are white and angular, and have been much used as a purgative and emmenagogue. They yield an oil by expression, which has been used as a local application in *rheumatic* and *paralytic affections*; also for *bad ulcers*.

CARUM (U. S. P.)—CARAWAY.

The fruit of *Carum Carvi*, Linné (*U. S. P.*) (*Carum Carui*, Linné).

Nat. Ord.—Umbelliferae.

COMMON NAMES: *Caraway-seed*, *Caraway-fruit*.

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 121; Köhler's *Medizinal Pflanzen*, Vol. I, Plate 91.

Botanical Source.—*Carum Carvi* (*Carui*) is a biennial plant, with a fusiform, fleshy root, and a stem about 2 feet high, erect, branched, leafy, angular, and furrowed. The lower leaves are nearly a span long, bright-green, petioled, doubly pinnate, with numerous opposite, finely-cut leaflets, of which the pairs next the midrib cross each other; those on the stem are much smaller, opposite, and very unequal. The umbels are numerous and erect. General bracts, if present, capillary, connected, when more than 1, by a membranous base. The flowers are numerous, white, or pale flesh-colored; marginal ones only perfect and prolific. Peduncles very small and convex. Calyx extremely minute; petals 5, obovate, inflexed. Stamens as long as the petals; anthers small, bilobed; ovary ovate. Fruit, or mericarps, narrow, bright-brown, elliptic-ovate, about 2 lines long, with pale, elevated, filiform ridges, and shining convex channels (L.).

History.—Caraway is indigenous to Europe, growing in the meadows and on the mountains of the South of France, and flowering from April to July. It is cultivated and appears wild also in Iceland, Scandinavia, throughout Russia, in Siberia, Persia, and the Caucasus. It grows wild in the Himalayas, and a peculiar form, an *annual*, differing in many ways, yet belonging to this species, is cultivated near Morocco. Caraway is also cultivated in Great Britain, Germany, Holland, and the United States. Its seeds are completed in the second year of its growth, when they mature in the latter part of summer. They are procured by beating the plant, after it has been removed from its place of growth. They are termed mericarps.

Description and Chemical Composition.—"Oblong, laterally compressed, about 4 or 5 Mm. ($\frac{1}{8}$ to $\frac{1}{4}$ inch) long, usually separated into the 2 mericarps, which are curved, narrower at both ends, brown, with 5 yellowish, filiform ribs, and with 6 oil tubes. Caraway has an agreeable odor, and a sweetish, spicy taste"—(*U. S. P.*). The virtues of caraway fruit are due to a volatile oil (see *Oleum Carui*), and are readily yielded to alcohol or ether. The oil is at first pale, becomes darker by age, and has the peculiar fragrance and taste of the seed. The immature fruits are rich in tannin. Resin, wax, mucilage, sugar, and a greenish fixed oil, were shown by Trommsdorff to exist in the fruit.

Action, Medical Uses, and Dosage.—Caraway is an aromatic carminative, used in *flatulent colic*, especially of children, and to improve the flavor of several medicinal compounds. The oil (*Oleum Carui*) is more generally used. The seeds are frequently added to cakes and confectionaries, to render them more agreeable, while, at the same time, they gently excite the digestive powers. Dose of the seeds, from 10 to 60 grains.

CARYOPHYLLUS (U. S. P.)—CLOVES.

"The unexpanded flowers of *Eugenia aromatica* (Linné), O. Kuntze"—(*U. S. P.*). (*Eugenia caryophyllata*, Thunberg; *Caryophyllus aromaticus*, Linné; *Myrtus caryophyllatus*, Sprengel).

Nat. Ord.—Myrtaceae.

COMMON NAME AND SYNONYM: *Cloves*; *Caryophylli aromatici*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 112.

Botanical Source.—*Eugenia aromatica* is a beautiful tree, rising to the height of 15 or 20 feet. It is of a conical or pyramidal form, evergreen, and the whole plant is glabrous. Its branches are numerous, slender, opposite, and more or less virgate. The wood of the stem is hard; the bark grayish and smooth. The leaves are opposite and decussate, persistent, somewhat coriaceous and shining, minutely punctated, about 4 inches long and half as broad, ovate-lanceolate, more or less

Fig. 59.

Eugenia aromatica, with fruit; and mother clove (to the left).

almost cylindrical, and 2-celled, with many small ovules in each cell. The berry is purplish, elliptical, and 2-seeded. The seed is covered with a thin integument of a soft texture (L.).

History.—A tall and beautiful tree, growing in tropical climates, extinct in its first habitat (Clove Islands), but introduced and extensively cultivated on the East Africa coast, and in the East and West Indies, and Brazil. The cultivated tree, from which the cloves are gathered, is not so tall as in the wild state, but its aromatic properties are much more pronounced. The flowers are collected twice yearly, in June and December, before they are fully developed, and just as they become bright-red, being either hand-picked or knocked from the tree with bamboo poles, falling upon a cloth outstretched to receive them. They consist of a tubular calyx, bearing a roundish bud of unexpanded petals; they are quickly dried in the sun, becoming thereby brown. The finest kinds are plump, heavy, and dark, and give out oil when squeezed with the nail. These are usually from East Africa and the Moluccas. A lighter-colored, shrunken variety comes from South America and the West Indies. Occasionally cloves from which the oil has been partially extracted, appear in market mixed with the better qualities. As a rule, they are deprived of their heads, and are in a moist state.

Description.—"About 15 Mm. ($\frac{1}{2}$ inch) long, dark-brown, consisting of a sub-cylindrical, solid and glandular calyx-tube, terminated by 4 teeth, and surmounted by a globular head, formed by 4 petals, which cover numerous curved stamens, and 1 style. Cloves emit oil when scratched, and have a strong, aromatic odor, and a pungent, spicy taste"—(U. S. P.). They yield their virtues to alcohol, spirit, and ether; water merely acquires their aroma.

Chemical Composition.—Cloves contain volatile oil, fixed oil, a peculiar tannin, gum, resin, fiber, water, and two crystalline principles called *caryophyllin* ($C_{20}H_{32}O$) and *eugenin* ($C_{10}H_{12}O_2$) (Trommsdorff). *Caryophyllin* is a camphor-like body which occurs in silky, needle-like prisms, without taste or odor, and of neutral reaction. It was isolated by Lodibert in 1825. *Eugenin* occurs in pearly white laminae, without taste. It was obtained in 1833, from the aqueous distillate of cloves, by Dumas, and named by Bonastre. *Caryophyllin* may be prepared by treating cloves previously deprived of the greater part of their volatile oil by means of a small quantity of alcohol, with hot ether. When treated with nitric acid it yields crystalline *caryophyllinic acid* ($C_{20}H_{32}O_6$) (E. Mylius, 1873). The active properties reside in the volatile oil, which is colorless or of a pale-yellow color, darkens by age, and is heavier than water. The yield from cloves is from 16 to 20 per cent. It is extremely pungent and acrid, and its principal constituent is *eugenol* ($C_{10}H_{12}O_2$), a fluid body (see *Oleum Caryophylli*).

Action, Medical Uses, and Dosage.—Aromatic, stimulant, and irritant. Used to allay vomiting and sickness at stomach, to stimulate the digestive functions,

and to improve the flavor or operation of other remedies, and prevent a tendency to their producing sickness or griping. Dose, from 5 to 10 grains.

Substituted Drugs and Related Species.—**CLOVE STALKS.** The dividing flower-stalks of cloves are frequently powdered to adulterate ground cloves, and occasionally are met in commerce intact. They have a pale-brownish hue, are about a line in thickness, and possess the characteristic clove taste and odor, though in feeble degree as compared with genuine cloves. They yield about $\frac{1}{4}$ as much essential oil as the latter, and are used to some extent in the distillation of clove oil. Their presence in powdered cloves may be shown microscopically by stone-cells (examined in glycerin after being treated with caustic potash), which are not found in clove-buds.

MOTHER CLOVES, *Anthophylli*.—Nearly ripe, dried clove-fruits. Oblong-oval, calyx-crowned, nearly an inch in length, resembling cloves to some extent, though yielding much less clove-oil. Microscopically detected in ground cloves by starch-cells of large size.

ROYAL CLOVES, *Caryophyllum regium*.—A monstrosity clove, small, having imperfect floral organs, sepals abnormal, and calyx-tube with bracts at base. Rare (*Pharmacographia*).

ALLSPICE (see *Pimenta*).—Occasionally used as an adulterant of ground cloves. Microscopically shown by starch-cells, together with stone-cells.

***Dianthus Caryophyllus*.**—The clove pink, selecting the deep-red and most fragrant flowers, is used in Europe to flavor and color a syrup.

CASCARILLA (U. S. P.)—CASCARILLA.

“The bark of *Croton Eluteria*, Bennett” (U. S. P.) (*Clusia Eluteria*, Linné).

Nat. Ord.—Euphorbiaceae.

COMMON NAMES AND SYNONYMS: Sweet-wood tree, Cascarilla-bark tree, *Eleuthera-bark tree*; *Cascarilla cortex* (Br.), *Cortex eluteriae*, *Cortex thuris*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 238.

Botanical Source.—*Croton Eluteria* is a small tree, said to rise to the height of 20 feet, and branching thickly at the top. The branches and twigs are angular, rather compressed, striated, downy, and ferruginous. The leaves are petiolated, alternate, ovate, with a short, but obtuse point, entire, slightly nerved, bright-green above, with a few scattered leprous dots, silvery, and very downy beneath. The petioles are short and scurfy. The racemes are axillary and terminal, branched or compound; the branches short, divaricating, and covered with numerous, closely-parted, subsessile, whitish, moncecious flowers. The sterile flowers are above and smallest; the fertile ones below, few, and on short stalks. The stamens, 10 to 12. The capsule is roundish, minutely warted, scurfy, and not much larger than a pea, with 3 furrows, 3 cells, and 6 valves (L.).

History.—The tree from which cascarilla is obtained is a native of the West Indies, and is found plentifully in the island of Eleutheria, from which it derives its name. It was, for a time, supposed to have been derived from the *Croton Cascarilla*, a small tree growing in the Bahamas, Hayti, Peru, and Paraguay, but this is now ascertained by botanists to have been an error. Cascarilla bark is imported from the Bahama Islands, Jamaica, etc. At one time it was known as *China nova*, on account of the resemblance of the external portion of the bark to that of cinchona, the latter having been adulterated and even substituted with cascarilla bark. The name *China nova* was subsequently applied to the bark of *Beuna magnifolia*, Weddell, a South American tree, noted for the magnificence of its foliage and the fragrance of its flowers (*Pharmacographia*). Our Pharmacopœial name—*Cascarilla*—is scarcely known in the Bahama Isles, the drug being there known as *Eleutheria*, or *Sweet-wood bark*. The name *Cascarilla* was first used in connection with cinchona bark, to which, by priority, it should apply, but it is now applied wholly to the sweet-wood bark. It signifies (Spanish) “little bark” (*Ibid*).

Description.—Cascarilla bark occurs “in quills, or curved pieces, about 2 Mm. ($\frac{1}{4}$ inch) thick, having a grayish, somewhat fissured, easily detached, corky layer, more or less coated with a white lichen, the uncoated surface being dull brown, and the inner surface smooth. It breaks with a short fracture, having a resinous and radially striate appearance. When burned, it emits a strong, aromatic, somewhat musk-like odor; its taste is warm and very bitter”—(U. S. P.). On account of its agreeable odor when burned, resembling that of musk, vanilla, or amber when heated, it is often added in small portions to tobacco, by smokers, to render the fumes more fragrant, but it produces unpleasant symptoms if used.

too freely. Water or spirit readily extracts its active principles, but diluted alcohol is the preferable menstruum.

Chemical Composition.—Trommsdorff found the bark to contain volatile oil, bitter resin, gum, and bitter matter with a trace of chloride of potassium, and woody fiber. Messner found oxide of copper in its ashes. Brandes detected a peculiar substance, *cascarilline*, which he took to be an alkaloid. Duval has found a neutral principle which he calls *cascarillin*, a disagreeable, fatty substance, an acid very much resembling tannic acid, etc. *Cascarilla* resembles salicin in many respects (*Amer. Jour. Pharm.*, Vol. XVII, 1845). In 1882, Alessandri, by abstracting the bark with a 2 or 3 per cent solution of oxalic acid, obtained a substance similar in behavior to Duval's *cascarillin*, with the difference, however, that Alessandri's substance was basic, evolving ammonia by warming with caustic potash, and forming salts with acids. R. A. Cripps, in 1886, could not obtain such a body. C. and E. Mylius, in 1873, confirmed Duval's observation as to the absence of nitrogen in *cascarilline*, for which they establish the formula $C_{12}H_{10}O_4$. Naylor and Littlefield obtained a purified *cascarillin*, having a melting point of $203.5^{\circ}C$. ($398.3^{\circ}F$), and the formula $C_{12}H_{10}O_4$. It yields a distillate related to anthracene ($C_{14}H_{10}$), when heated with zinc dust (*Amer. Jour. Pharm.*, 1896). Conrady found *vanillin* in *cascarilla* bark (1895).

Action, Medical Uses, and Dosage.—Tonic and stimulant. Used in *dyspepsia*, *flatulency*, *chronic diarrhæa*, in *debility* attending chronic diseases, convalescence from acute diseases, and to arrest *vomiting*. When cinchona produces nausea, the addition of *cascarilla* will prevent it. Dose of the powder, from 20 to 40 grains; of the tincture, from 1 to 4 fluid drachms; of the infusion, from 1 to 4 fluid ounces. On account of its musky odor, it is a common ingredient of fumigating pastiles.

Related Species.—*Croton pseudo-china*, Schlechtendal (see *Aspidosperma*), *Croton Malambo*, Karsten, *Malambo bark*. Venezuela. Bark resembles *cascarilla* in taste and odor. It is quilled, brown externally, and transversely grooved. Grayish-brown internally, and finely marked with striae. The cork-layer is nearly white, soft, not thick, and fissured lengthwise. It has an abrupt splintery fracture. Used by the natives in *dysentery*, *atonic dyspepsia*, *worms*, *spasms*, *yellow and intermittent fevers*, *asthma* and *trismus nascentium*.

CASSIA FISTULA (U. S. P.)—CASSIA FISTULA.

"The fruit of *Cassia Fistula*, Linné" (U. S. P.) (*Bactrylobium Fistula*, Willdenow; *Cathartocarpus Fistula*, Persoon).

Nat. Ord.—Leguminosæ.

COMMON NAME AND SYNONYM: *Purging cassia*; *Fructus cassiæ fistulæ*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 87.

Botanical Source.—*Cassia fistula* is a tree growing from 20 to 40 feet high, with many spreading branches toward the summit. The wood is hard and heavy. The leaves pinnate, alternate, from 12 to 18 inches long, and deciduous; the leaflets opposite or nearly so, from 4 to 8 pairs, the lower ones broad-ovate, smooth, obtuse, or emarginate, polished on both sides, on short, round petioles, from 2 to 6 inches long, and from $1\frac{1}{2}$ to 3 broad. The flowers are large, fragrant, bright-yellow, and borne on long, slender, smooth pedicels. The racemes are axillary, pendulous, simple, and 1 or 2 feet long. The calyx is composed of 5 nearly equal, oblong, obtuse, smooth sepals. The corolla consists of 5 petals, which are oval, unequal, concave, spreading, and waved. The 3 lower filaments, much longer than the others, have a double curve, but no swelling. The anthers on the 3 long filaments are oblong, opening by 2 lines on the face, while the other 7 are clavate, with pores at the small end. The ovary is filiform, smooth, cylindrical, curved, and 1-celled, containing numerous seeds. The fruit is a woody, dark, blackish-brown, cylindrical pod or legume, a foot or more in length, about an inch in diameter, terete, smooth, blunt, indehiscent, filled with a viscid, reddish-black, sweetish pulp, divided into many cells by hard, transverse phragmata; the cells 1-seeded; and the seed oval, glossy, and somewhat flattened (L.).

History.—*Purging cassia* inhabits Egypt and the Indies, and has become extensively diffused in various tropical countries, as China, Hindustan, West Indies, Brazil, etc. The part used in medicine is the fruit or pods, and those are to be preferred which are heavy and new, and do not, when shaken, make a

rattling noise from the seeds being loose within them. The pulp should be of a bright, shining, black color, and have a sweet taste, neither harsh, from the fruit being collected before it is fully ripe, nor at all sourish, which it is apt to become on keeping, nor at all moldy, which is frequently the case when kept in damp cellars, or moistened to increase its weight (*Ed.*) To obtain the pulp, the pods are pounded, so as to break their outer coat, and then they are infused in boiling water, which dissolves the pulp; the infusion is then strained, and evaporated to the proper consistence.

Description.—"Cylindrical, 40 to 60 Cm. (16 to 24 inches) long, nearly 25 Mm. (1 inch) in diameter, blackish-brown, somewhat veined, the sutures smooth, forming two longitudinal bands; indehiscent, internally divided transversely into numerous cells, each containing a reddish-brown, glossy, flattish-ovate seed imbedded in a blackish-brown sweet pulp; odor resembling that of prunes"—(*U. S. P.*).

Chemical Composition.—The pulp has a feeble, nauseous odor, a mucilagino-saccharine taste, and contains, according to Henry, sugar, gum, impure tannic acid, coloring matter, a gluten-like matter, and moisture. It keeps longest when preserved in the pod. It is largely soluble in water, and its active parts are taken up by alcohol.

Action, Medical Uses, and Dosage.—One or two drachms act as a mild and effectual laxative; 1 or 2 ounces are cathartic, but excites nausea, flatulence, gripings, etc. (*Ed.*). It tints the urine brown or green. It is generally employed only in the electuary of senna.

Related Species.—*Cassia moschata*, Kunth (*Cathartocarpus moschatus*, Don). Central and northern South America. Yields a purging cassia, resembling the official, though not quite so uniformly straight, and is from a foot to nearly 20 inches long, and of a light color. Its pulp is sweet, subastringent, and of a reddish-brown color. A sandal-wood fragrance is emitted when the crushed legumes are heated in a water-bath (*Pharmacographia*).

Cassia bacillaris, Linné filius (*Cathartocarpus bacillus*, Persoon).—Yields a drug essentially corresponding with the preceding.

Cassia brasilianna, Lamarck (*Cassia grandis*, Linné filius; *Cathartocarpus brasilianna*, Persoon; *Cassia mollis*, Vahl), *Horse cassia*.—Brazil and Central America. Larger than purging cassia legumes; sutures prominent, and pulp astringent, bitter, and purgative. They are compressed, may be curved, and have dividing veins running transversely.

Ceratonía siliqua, Linné.—Mediterranean countries. An evergreen tree bearing purple, apetalous flowers, and producing a fruit known as *St. John's bread*, somewhat resembling purging cassia. Employed in Europe in connection with demulcents and pulmonary mixtures. Besides sugar and glucose, mucilage, tannic acid, and proteids, the fruit contains free isobutyric acid ($[\text{CH}_3]_2\text{CH.COOH}$). A more recent analysis of *Ceratonía siliqua* is recorded in the *Amer. Jour. Pharm.*, 1893, p. 131.

CASSIA MARILANDICA.—AMERICAN SENNA.

The leaves of *Cassia marilandica*, Linné.

Nat. Ord.—Leguminosæ.

COMMON NAMES: *American senna*, *Wild senna*.

Botanical Source.—*Cassia marilandica* is an American, perennial herb, growing from 4 to 6 feet high, with round, striated, smooth, or slightly hairy stems.

The leaves are alternate, on long petioles, at the base of which is a large, ovate, shining green gland, terminating in a dark point at top, which is sometimes double; each petiole contains from 8 to 10 pairs of leaflets, which are oblong, smooth, entire, mucronate, somewhat hairy at the edges, 1 or 2 inches long, and from 5 to 10 lines broad. The flowers are bright yellow, in axillary racemes, extending quite to the top of the stem; the peduncles are slightly furrowed, and marked with minute, blackish, glandular hairs; sepals 5, oval, obtuse, the lateral ones longest. Petals 5, concave, and very obtuse. Stamens 10, the 3 upper have short abortive anthers; to these succeed 2 pairs of deflexed, linear, brown anthers; the remaining lowermost 3 taper into a sort of beak, the middle one being shortest. The fruit is a legume, from 2 to 4 inches long, pendulous, linear, curved, swelling at the seeds, furnished with slight hairs; seeds many (L.). It is sometimes called wild senna.

Fig. 60.

Cassia marilandica.

History and Chemical Composition.—This plant is frequently met with in alluvial soils, and in stony situations, from New England to North Carolina, flowering from June to September, about which time the medicinal parts of the plant should be gathered. The leaves yield their properties to alcohol or water; they are nearly odorless, have a senna-like, mawkish taste, and in medicinal power are equal to foreign senna. Mr. Martin, of Philadelphia, found the leaves to contain albumen, mucilage, starch, chlorophyll, yellow coloring matter, volatile oil, fatty matter, resin, lignin, salts of potassium and calcium, and a principle resembling cathartin (*Amer. Jour. Pharm.*, Vol. I, p. 22). It is also thought to contain chrysophan and cathartic acid (*Amer. Jour. Pharm.*, 1888, p. 231).

Action, Medical Uses, and Dosage.—An excellent cathartic, equal to the imported article, for which it may be substituted. But owing to the presence of argel leaves, much of the foreign senna has its activity increased; hence, in giving the American article, its dose must be somewhat increased. It may be given in powder or infusion, and should be combined with aromatics to prevent any proneness to griping. The dose in powder is from $\frac{1}{2}$ to $2\frac{1}{2}$ drachms. The infusion may be made by adding 1 ounce of the leaves, with 1 drachm of coriander seeds, to 1 pint of boiling water. Macerate for an hour in a covered vessel and strain; dose, 4 or 5 fluid ounces.

Related Species.—*Cassia Chamæcrista*, Linné. *Prairie senna* or *Partridge pea*, growing on the western prairies, is an excellent substitute for the above; it is likewise known as *Dwarf cassia* and *Sensitive pea*.

CASTANEA (U. S. P.)—CASTANEA.

"The leaves of *Castanea dentata* (Marshall) Sudworth; collected in September or October, while still green"—(*U. S. P.*). *Castanea vesca* (Gaertner), var. *Americana*, Michaux; *Castanea vesca*, Michaux (*Sylv.*, Vol. III, p. 11); *Fagus Castanea*, Linné; *Castanea vulgaris*, Lamarck; *Fagus Castanea dentata*, Marshall).

Nat. Ord.—Cupuliferae.

COMMON NAME: Chestnut.

ILLUSTRATIONS: *Flora of New York*, Plate 111; Michaux's *Sylv.*, Vol. III, Plate 104; Emerson's *Trees of Mass.*, p. 187.

Botanical Source.—This is a large, well-known tree, the flowers of which appear in June and July, after the leaves are full grown, and when all other forest

FIG. 61.

Castanea dentata.

trees have blossomed; they are small, apetalous, and monœcious. The sterile flowers are very numerous, in long, erect, white, rigid aments, which emit an unpleasant odor. The stamens are from 8 to 20, and have slender filaments. The fertile flowers are 2 or 3, enclosed in a scaly involucre. The fruit is a 4-valved burr, armed on the outside with stiff, sharp, bristles, and lined on the inside with a soft, velvety pubescence. It encloses 3 (or often, by abortion, 1 or 2) edible nuts. The leaves are alternate, lanceolate, and coarsely toothed, tapering to a slender point, and are borne on leaf-stalks about $\frac{1}{2}$ inch long; the veins are parallel, rigid, and terminate in the mucronate points of the teeth.

History.—The chestnut is a large tree, originally a native of Asia Minor, but introduced and extensively naturalized in the temperate parts of Europe. The

American tree (var. *Americana*, Michaux), differs slightly from the European, in having smaller fruit, and leaves acute at the base. It is found from Maine to the gulf states, being especially abundant in the Alleghany regions.

Chestnut leaves should be gathered in the fall, before frost, and carefully dried in the shade. They are of a greenish color, and exhale a pleasant, tea-

like odor. At first, slightly astringent to the taste, they become mucilaginous and sweetish when chewed, leaving an after-taste, very much resembling that of *Solanum Dulcamara*.

Description and Chemical Composition.—"From 15 to 25 Cm. (6 to 10 inches) long, about 5 Cm. (2 inches) wide, petiolate, oblong-lanceolate, acuminate, mucronate, feather-veined, sinuate-serrate, smooth; odor slight; taste somewhat astringent"—(*U. S. P.*). The chief constituent of chestnut leaves is a mucilaginous substance which is slowly extracted from the shredded leaves by means of cold water, and more freely by hot, but which is insoluble in alcohol. Any preparation of the leaves which does not contain this material will fail to relieve the paroxysms of whooping-cough, and, for this reason, but little alcohol is admissible in the fluid extract, and thus, undoubtedly, the best preparation is freshly prepared infusion or decoction. Chestnut leaves also contain an astringent principle, and a sweet substance, the other constituents, seeming to be simply those found in most plants. The ash consists of potassium, calcium, magnesium, and iron salts. The testa of the seeds is said to contain a bitter principle.

Action, Medical Uses, and Dosage.—Chestnut leaves appear to have been brought into notice, as a therapeutical agent, by Mr. G. C. Close, in a statement before the American Pharmaceutical Association, in 1862. Subsequently, they were employed by the late Dr. J. S. Unzicker, of Cincinnati, who valued them highly in the treatment of *whooping-cough*; since which, most favorable reports have been made by other physicians, as to their value. These leaves have, thus far, been employed mainly in the treatment of *pertussis*, in which malady they have proved remarkably efficient; but their manner of action has not yet been determined. It is very probable that they may be found useful in other irritable or excitable conditions of the respiratory nerves. Dr. Unzicker employed an infusion of the leaves, an ounce to a pint of boiling water, and administered this in tablespoonful, or small wineglassful doses, repeated several times a day. The fluid extract, when properly made, will be found reliable; its dose is from $\frac{1}{2}$ to 1 fluid drachm, repeated 3, 4, or 5 times daily. Chestnut bark appears to possess astringent and tonic properties, and is used in some sections of our country as a popular remedy for *fever* and *ague*. Other forms of paroxysmal or convulsive *cough* resembling *pertussis* have been cured with it. Prof. Scudder (*Spec. Med.*, p. 103), suggests a trial of the remedy in cases exhibiting unsteadiness of gait and a disposition to turn to one side.

Specific Indications and Uses.—Paroxysmal, convulsive cough; *pertussis*.

Related Species.—*Castanea pumila*, Michaux (*Fagus pumila*, Linné), an allied species commonly called "*Chincapin*," or "*Chinquapin*," is a shrub or small tree found in sterile places from Ohio southward. The flowers, leaves, and fruit of this species bear a close resemblance to those of *C. dentata*, but are all smaller. The fruit encloses but a single seed, which is not flattened as are the seeds of *C. dentata*. (For a monographic description, see Henry Kraemer, *A. P. A. Proc.*, 1896.)

CASTOREUM.—CASTOR.

The præputial follicles (dried), with their secretions, taken from the common beaver, *Castor Fiber*, Linné. (*Castor americanus*, Cuvier).

Class.—Mammalia. *Order.*—Rodentia.

Source, History, and Description.—This drug is a peculiar solidified secretion procured from peculiar follicles, two in number, connected with the external genital organs of the *Castor Fiber*, or *Beaver*. These follicles are filled with a thick fluid secretion, which slowly concretes when they are removed from the animal. Most of the castor of the present day is derived from the beaver of North America. It has much the appearance of a pair of dried testicles united by their spermatic cords, dark liver-brown and wrinkled externally, paler liver-brown internally, resinous in fracture, when perfectly dried of a strong, peculiar heavy odor, and an aromatic, bitter, offensive taste. Rectified spirit is its best solvent; though ether extracts a good part of its virtues.

The Russian castor, from the Russian dominions, is seldom seen in this country; it may be distinguished from the American by being more fully developed, weightier, and less cohesive, by its more powerful odor, resembling that of

Russian leather, and its taste, and by effervescing with hydrochloric acid. The American castor gives a white precipitate with aqua ammoniæ, the Russian, an orange-yellow. Castor deteriorates by age, which is hastened by elevated temperatures; a damp atmosphere readily spoils it. When kept in a cool situation, in well-closed vessels, its virtues will continue uninjured for some years. A tasteless and inodorous article is inert. A spurious castor is sometimes met with, which is composed of several drugs combined, intermixed with dried laminæ of mucous tissue, odorized by a small portion of good castor, and then placed within a goat's scrotum. The deficiency of the little follicles which hold a fatty substance, the faint smell, and the feeble castor taste, and the want of other determinate characters, will at once expose the imposture (P.—Ed.). On the other hand, W. Fossek observed a pathological specimen of Russian origin, which was decomposed and contained 21 per cent ash, as against only 2 per cent from good castoreum; this was due to the formation of globular pathological concretions containing calcium (Amer. Jour. Pharm., 1892).

Chemical Composition.—Castor is composed of numerous salts, mucus, a volatile oil, a resinous substance (to which its acrid bitterness is due), a horny matter, osmazome, and a peculiar crystalline, non-saponifiable principle called *castorin*. Wöhler detected *salicin* and *carbolic acid* in castor. The former is probably derived from the food of the beaver, which lives on salicin-producing barks; and carbolic acid is thought by Lehmann, to be derived from the birch-wood fires over which the drug is dried. Wöhler also found *benzoic acid* present. Pereira found salicyl-aldehyde in *Aqua Castorei* prepared from American castor.

Action, Medical Uses, and Dosage.—Mildly stimulant, antispasmodic, and emmenagogue. Used in *hysteria*, *amenorrhœa*, *epilepsy*, and many irregular *nervous affections*. Dose of the drug, from 10 to 20 grains; of the tincture, from $\frac{1}{2}$ fluid drachm to 2 fluid drachms.

Cramer, in 1888, claims to have discovered in the tincture of castor (castor 1, alcohol 5) a remedy for breaking off the *morphine habit* (Amer. Jour. Pharm., 1888, p. 177). It has also been used among the Cree Indians to prepare a poultice for *sprains* (Amer. Jour. Pharm., 1884).

CATALPA.—CIGAR TREE.

The bark of *Catalpa bignonioides*, Walter (*Catalpa syriacifolia*, Sims; *Bignonia Catalpa*, Linné; *Catalpa cordifolia*, Nuttall).

Nat. Ord.—Bignoniaceæ.

COMMON NAMES: *Cigar-tree*, *Catalpa-tree*, *Bean-tree*, *Indian bean-tree*.

ILLUSTRATIONS: Michaux, *F. Sylv.*, Vol. II, Plate 64; *Bot. Mag.*, Plate 1094.

Botanical Source.—This handsome tree has leaves that are large, heart-shaped, opposite or disposed in whorls of 3. The flowers appear in June and July, and are produced in large, showy, terminal, compound panicles. The corollas are about an inch long, white, tinged with purple, and studded with orange spots in the tubes. They are bell-shaped, with a swollen tube, irregularly 5-lobed and 2-lipped. The fruit is a slender, 2-celled capsule, about 1 foot long, $\frac{1}{2}$ of an inch thick, and hangs suspended until spring. The seeds are numerous and winged.

History.—This tree is a native of the southern United States, but is cultivated as an ornamental tree and frequently naturalized in the northern states. It belongs to the natural order *Bignoniaceæ*, and, except a western states species, the *Catalpa speciosa* of Warder, is the only indigenous species of *Catalpa*, although others are found in Asia and the West Indies. The tree is called "cigar-tree," or "bean-tree," names derived from the slender fruit. The fruit and seeds have also been used.

Description.—The bark of the trunk is scaly, brown, and from 3 to 6 lines in thickness. That of the young limbs, is smooth, dark-grayish, and spotted with lighter colored excrescences. The young bark, and the inner portion of the old, is bitter. *Catalpa* wood is very durable, rivalling cedar. It is hard, grayish, and of coarse fiber.

Chemical Composition.—In 1870, Eugene A. Rau (Amer. Jour. Pharm.) made an examination of the inner bark of the tree, and found it to contain tannin, and

a nauseating matter soluble in ether. When this substance was boiled with water and oxide of lead, and then filtered, a yellowish solution was obtained, free from alkaloids, and very bitter. The precipitate that separated with the oxide of lead, gave to boiling alcohol a crystallizable, white, neutral substance, which possessed the nauseating bitter taste of the bark, and was soluble in ether and chloroform. In addition to the above, an insipid resin and glucose were obtained. The seeds, when extracted with a mixture of alcohol, ether, and ammonia, yielded several crystallizable principles (Brown, 1887). Sugar, tannin, resin, and fixed oil are also constituents of the seeds.

Action, Medical Uses, and Dosage.—It is stated that poisonous emanations issue from this tree, but we have no knowledge of any serious effects resulting from an exposure thereto. The pods and seeds have been employed in decoction in *chronic bronchial affections, spasmodic asthma, and dyspnoea*, and certain forms of *functional heart disease*; 6 or 8 ounces to a pint of water, and given in tablespoonful doses, repeated every 1 or 2 hours. The leaves, bruised, and applied as a cataplasm, have been used in *irritable scrofulous ulcers*; they appear to possess anodyne properties. The bark has been employed internally, in powder, or in decoction, in *scrofulous maladies*, and as an anthelmintic. The juice of the leaves, as well as of the root, has been beneficially employed as a local application in the several forms of *strumous ophthalmia*, as well as in certain *cutaneous affections*. From the statements that have been made as to the toxic properties of this tree, and which have not yet been satisfactorily demonstrated, it would be advisable to use some prudence and care in the internal administration of any of its preparations. Dose of specific catapla, fraction of a drop to 20 drops.

Related Species.—*Bignonia cupreolata*, Linné. Southern United States. *Trumpet creeper*. A shrub of climbing habit, bearing large orange-colored flowers. Aqueous preparations of the stems and root of this species have been used, according to Porcher, for the same purposes as sarsaparilla—i. e., in *syphilis, chronic rheumatic complaints*, and other disorders dependent upon blood dyscrasia. It is reputed alterative, detergent, sudorific, and diuretic. A closely related plant is the *Tecoma radicans*, Jussieu, known as *Trumpet flower*.

CATAPLASMATA.—CATAPLASMS.

SYNONYM: *Poultices*.

Cataplasms, ordinarily called "poultices," are preparations designed to be applied externally for the purpose of producing relaxation, holding moisture, and allaying pain and inflammation. They are usually composed of substances capable of absorbing considerable fluid, and are applied either cold or warm, in a moist state. They should not be made so thin as to flow over the parts adjacent to their application, nor so thick as to become dry too rapidly; neither should they be composed of substances which stick too tenaciously to the skin and are not readily removed by water; nor of hard bodies. They should always be removed without being permitted to dry. Owing to the affections for which they are applied, and their influence upon these, they have received the several names of emollient, discutient, refrigerant, stimulating, etc. When applied to ulcers, tender and irritable parts, etc., it is customary to cover their surfaces with a little olive oil, in order to prevent adhesion to such parts. Poultices are commonly prepared by nurses, but physicians and druggists should be acquainted with their method of preparation.

Spongio-piline is sometimes applied to parts to absorb excessive moisture, or to prevent evaporation. It is a thick cloth composed principally of sponge, one side of which is applied to the skin in a wet or dry state, according to the action required; the other side being coated with some water-proof varnish, or with rubber. It may likewise be used to apply moisture to a part or may be saturated with medicated solutions and applied to the affected part.

CATAPLASMA CARBONIS.—CHARCOAL POULTICE.

SYNONYM: *Charcoal cataplasm*.

Preparation.—Macerate bread, 2 ounces, with water, 10 fluid ounces, for a short time near the fire; then gradually add and mix with it powdered flaxseed,

10 drachms, stirring so as to make a soft cataplasm. With this mix powdered charcoal 2 drachms, and when prepared for application, sprinkle 1 drachm of charcoal on the surface of the cataplasm (*Lond.*).

The *British Pharmacopœia* differs merely in directing $2\frac{1}{2}$ ounces of linseed-meal, and in employing $\frac{1}{2}$ ounce of wood charcoal.

Action and Medical Uses.—Charcoal, properly prepared, has the property of removing the fetid odor evolved by *gangrenous* and *phagedenic ulcers*, for which the above cataplasm is designed. It should be renewed 2 or 3 times in every 24 hours.

CATAPLASMA CONII.—HEMLOCK POULTICE.

SYNONYMS: *Hemlock cataplasm*, *Conium cataplasm*.

Preparation.—This poultice is official in the *British Pharmacopœia*, and is prepared as follows: One fluid ounce of hemlock juice is evaporated to $\frac{1}{2}$ fluid ounce, and this is added to a mixture of 4 ounces of linseed-meal in 10 ounces of boiling water, and the whole stirred together. Conium extract may be substituted for hemlock juice if so desired, though the juice only is directed by the above-mentioned authority.

Action and Medical Uses.—This poultice is desirable when a preparation of this class is needed with pain-relieving properties. It has been employed in *malignant sores*, being especially valuable in *cancer*.

CATAPLASMA DAUCI.—CARROT POULTICE.

SYNONYMS: *Cataplasma carotæ*, *Carrot cataplasm*.

Preparation.—Take of garden carrots, scraped, 4 ounces, Indian meal, 1 ounce, boiling water, a sufficient quantity to form a cataplasm of the proper consistence.

Action and Medical Uses.—This will be found a valuable application to *indolent* and *gangrenous ulcers*, and *painful tumors*.

CATAPLASMA FERMENTI.—YEAST POULTICE.

SYNONYM: *Yeast cataplasm*.

Preparation.—To $\frac{1}{2}$ pint of milk, tepid, add yeast, 2 fluid ounces, and fine slippery-elm bark, a sufficient quantity to form a cataplasm of the proper consistence (*Beach's American Practice*).

The *British Pharmacopœia* directs that 6 fluid ounces of beer yeast be mixed with 6 fluid ounces of water (at 37.7° C. [100° F.]), after which 14 ounces of wheat flour is stirred into the yeast mixture, and the mixture placed near the fire until fermentation ensues, causing it to rise through the liberation of carbon dioxide.

Action and Medical Uses.—This is valuable as an antiseptic application. It will be found especially serviceable in *gangrenous* and *phagedenic ulcerations*; it destroys the fœtor, often checks the sloughing, and assists the separation of the dead parts. It should be renewed 2 or 3 times a day. Five or 10 drops of carbolic acid stirred in this poultice, will augment its antiseptic virtues.

CATAPLASMA LINI.—LINSEED POULTICE.

SYNONYMS: *Flaxseed poultice*, *Linseed cataplasm*, *Flaxseed cataplasm*, *Cataplasma emolliens*, *Cataplasma communis*.

Preparation.—To boiling water, 10 fluid ounces, add gradually, powdered flaxseed, $4\frac{1}{2}$ ounces, or a sufficient quantity; stir constantly, so as to make a cataplasm (*Lond.*).

The *British Pharmacopœia* directs 4 ounces of linseed-meal. If American "cake-meal" be employed, the addition of about $\frac{1}{2}$ ounce of olive oil will be necessary. Some prefer a mixture of linseed-meal and cake-meal for this purpose.

Action and Medical Uses.—This is a valuable emollient cataplasm, to allay pain, inflammation, and favor suppuration. It is used for similar purposes with the elm poultice. If it should decompose, as it is apt to do, it may vesicate, or at least cause a pustular eruption, sweet oil, lard, glycerin, or olive oil may be mixed with or spread upon the poultice, both as a preservative and preventive. Flaxseed poultice causes the skin to be blanched, sodden, and wrinkled. Flaxseed poultice is frequently employed in *acute pulmonary disorders*.

CATAPLASMA LOBELIÆ.—LOBELIA POULTICE.

SYNONYM: *Lobelia cataplasm*.

Preparation.—To equal parts by weight of powdered lobelia and fine elm bark, add a sufficient quantity of weak lye, warm, to form a cataplasm.

Action and Medical Uses.—This forms an excellent application to *felons, white-swelling, wounds, fistula, inflammation of the breast and other parts, stings of insects, erysipelatous inflammations, and painful swellings or ulcerations*. It should be frequently renewed.

CATAPLASMA OXYCOCCL.—CRANBERRY POULTICE.

SYNONYM: *Cranberry cataplasm*.

Preparation.—Take of ripe cranberries, any quantity, and bruise them to form a cataplasm.

Action and Medical Uses.—Applied around the throat in *quinsy*, and in swelling of the glands of the throat in *scarlatina* and other diseases, its action is prompt. It has been likewise reputed useful in *cancerous ulcers, erysipelatous inflammation, and gouty rheumatism*. A split cranberry, secured in position by a daub of starch, is recommended for *boils* on the tip of the nose, when a poultice can not be retained in place.

CATAPLASMA PHYTOLACCÆ.—POKE-ROOT POULTICE.

SYNONYMS: *Phytolacca poultice, Poke-root cataplasm*.

Preparation.—Place fresh poke-root in hot ashes to roast, when sufficiently done, mash it and form a cataplasm.

Action and Medical Uses.—This may be applied to all kinds of *tumors* in order to discuss them; or if they be too far advanced, it will hasten suppuration. In the latter instance its action is accompanied with much pain. It is applicable when it is desired to hasten suppuration in *mastitis*. It is especially valuable in tumors of an indolent character, as *buboes*. It should be renewed 2 or 3 times a day.

CATAPLASMA SINAPIS.—MUSTARD POULTICE.

SYNONYMS: *Sinapiemus, Sinapism, Mustard cataplasm, Cataplasm rubefaciens*.

Preparation.—The *British Pharmacopœia* directs 2½ ounces of mustard (composed of both ground white and black mustard) to be mixed with 2 or 3 ounces of water (lukewarm). This is to be stirred into a mixture of 2½ ounces of linseed-meal, made with boiling water (6 or 8 ounces). Mustard should not be mixed with hot water, and it is altogether probable that, by mixing the above mixture of flaxseed and boiling water, the poultice is rendered less effective on account of the volatilization of a portion of the volatile oil of the mustard. The *French Codex* simply directs the preparation of 200 Gm. [7 oz. av., 24 grs.] of black mustard-meal, recently prepared, to be mixed with water (scarcely tepid) until a poultice-consistence is obtained. A simple method is to mix flour, or flaxseed, with ground mustard, and mix with sufficient water to form a poultice. Vinegar should not be employed in making mustard poultices.

Action and Medical Uses.—Mustard poultice is powerfully stimulant to the skin, the rubefacient effect being quickly produced, and, if long applied, vesication may ensue. A mustard plaster produces intolerable burning. Gangrenous ulcerations have been produced by the careless and prolonged application of these poultices. The black mustard is stronger than the white, and, as a rule, the former should not be left in contact with the skin longer than 20, nor the latter longer than 30 minutes. Care should be exercised in applying them to children. It is best to have a thin piece of gauze or other fabric between the surface of the poultice and the skin, the hairs of the latter having been previously shaved off. (For *Uses*, see *Sinapis*. For *Mustard plaster*, see *Charta Sinapis*).

CATAPLASMA SODÆ CHLORINATA.—CHLORINE POULTICE.

SYNONYMS: *Chlorine cataplasm, Chlorinated soda poultice.*

Preparation.—Gradually mix 4 ounces of linseed-meal with 8 fluid ounces of boiling water, and add to the mixture, with constant stirring, 2 fluid ounces of solution of chlorinated soda (Labarraque's solution).

Action and Medical Uses.—This poultice is official in the *British Pharmacopœia*, and may be employed where yeast poultice is indicated. It has a stimulant action on old *sloughing ulcerations*, and corrects the fetid emanations arising therefrom.

CATAPLASMA STRAMONII.—STRAMONTIUM POULTICE.

SYNONYM: *Stramonium cataplasm.*

Preparation.—Take of the fresh leaves of stramonium, *any quantity*, bruise them, and add a small quantity of hot water, to form a sufficiently moist cataplasm.

Action and Medical Uses.—I have found this a decidedly efficient application in *peritoneal inflammation*, the whole abdomen to be covered with it; likewise in *acute rheumatism*, and in *gastro-intestinal inflammations*. Applied to the perineum in *enlargement of the prostate*, for the purpose of securing the passage of the catheter in case of retention of urine, when it can not otherwise be entered into the bladder, I know of no better agent—it should remain on the parts about an hour before attempting the introduction of the catheter. It will be found valuable in *rheumatic or neuralgic pains* (Prof. J. King, M. D.).

CATAPLASMA ULMI.—ELM POULTICE.

SYNONYMS: *Elm cataplasm, Slippery-elm poultice.*

Preparation.—Take of powdered elm bark (*Ulmus fulva*) a *sufficient quantity*; stir it in hot water, or milk and water, to the consistence of a cataplasm (Beach's *American Practice*).

Action and Medical Uses.—This cataplasm is of almost universal application, and is superior, in many respects, to every other. As an application to *painful swellings, inflammations, ulcerations*, and to facilitate the separation of the slough produced by caustics, and for various other purposes, it stands, and justly, too, in high repute among American physicians.

Other Cataplasms.—I. **BREAD POULTICE.**—Take crumbs of bread, *any amount*, and heat with sufficient sweet milk to form a cataplasm. A little fresh lard may be added, which prevents the skin from becoming sodden and wrinkled. It forms a good emollient poultice, but should be frequently renewed.

II. **MOLASSES POULTICE.**—New Orleans molasses, a *sufficient quantity*, add wheat flour, enough to form a soft, easily-spreading mass. This is, according to Prof. J. U. Lloyd, one of the very best applications for *burns and scalds*, and his standard laboratory application, where scalds are not infrequent. It should be spread upon a cloth and the burned surface bound up in it.

III. **INDIAN-MEAL POULTICE.**—Corn-meal, a *sufficient quantity*. Stir gradually into boiling water until of the desired consistence. An excellent emollient application. In the form of a mush-jacket, it is much employed in *acute pulmonary and pleural inflammations*. When pre-

pared with a hot decoction of black-willow bark (*Salix nigra*), it forms an excellent application to surfaces poisoned by *Rhus Toxicodendron* and other species of poison vine.

IV. **POTATO POULTICE.**—Mashed boiled potatoes spread upon inflamed surfaces are often useful, being peculiarly effective in *acute arthritic rheumatism*. Grated raw potato is also a useful application for inflammatory disorders, and especially valuable in inflammations of the face and eyelids. It will stain clothing black.

V. **ALUM POULTICE.**—This is prepared by coagulating with 1 drachm of alum, the albumen, or fluid whites, of 2 eggs. It is employed where a cooling and astringent cataplasm is required.

CATARIA.—CATNIP.

The leaves and flowering tops of *Nepeta Cataria*, Linné (*Cataria vulgaris*, Moench).

Nat. Ord.—Labiatae.

COMMON NAMES AND SYNONYMS: *Catnip*, *Catmint*, *Catnep*; *Herba nepetae*, *Herba catariae*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 209.

Botanical Source and Description.—Catnip or catmint is a perennial herb, with an erect, square, hoary-tomentose, branching stem, 2 or 3 feet in height. The leaves are opposite, cordate, oblong, petiolate, coarsely crenate-serrate, and covered with a soft, hoary down, paler beneath. The flowers are many, white, or purplish, in whorled spikes, which are slightly pedunculated, the lower lip dotted with crimson. The calyx is dry, striate, tubular, obliquely 5-toothed. The corolla is naked and dilated in the throat, 2-lipped, twice the length of the calyx; upper lip rather concave, erect, notched, or 2-cleft; lower spreading, 3-cleft, middle lobe largest and crenate. The stamens are 4, ascending under the upper lip; anthers approximate in pairs, the cells divergent (G.—W.).

History.—Catnip is a very common, naturalized plant, growing about old buildings and fences, and on waste and cultivated lands, flowering from June to September. It is a native of Europe. The tops and leaves are medicinal; they have a strong, characteristic odor, not very grateful to many persons, and a peculiar, bitterish taste. Their virtues are imparted to boiling water by infusion. It is very much liked by cats, preventing, it is said, attacks of fits.

Catnip should be collected each year in June and July, when flowering, and the coarser stems and branches rejected. It deteriorates in value, hence the necessity of gathering it annually. A variety, *Nepeta Cataria*, Linné, var. *citriodora*, Becker, has the odor of lemon or balm.

Chemical Composition.—Its active constituents are an oxygenated essential oil, and tannic acid striking a green color with ferruginous salts. Mr. H. R. Gillespie, in 1889, detected in catnip both fixed and volatile oils, mucilage, sugar, dextrin, a crystallizable wax, and a bitter body, neither glucosidal nor alkaloidal in character, but having acid properties.

Action, Medical Uses, and Dosage.—Catnip is diaphoretic and carminative in warm infusion; tonic when cold. It is also antispasmodic, emmenagogue, and diuretic. In warm infusion it is used in *febrile diseases* as a diaphoretic, and to promote the action of other diaphoretics, as well as to allay spasmodic action and produce sleep; it is also given as a carminative and antispasmodic in the *flatulent colic* of children; and as an emmenagogue or uterine tonic, it has proved decidedly beneficial in *amenorrhœa* and *dysmenorrhœa*, and has likewise been successfully employed in *nervous headache*, *hysteria*, and *nervous irritability*. The leaves are reputed beneficial in *toothache*, when masticated and applied to the decayed tooth. A warm infusion of saffron and catnip is a very popular and beneficial remedy in *colds*, *febrile* and *exanthematous diseases* to which infants and young children are subject. The infusion is very efficient in allaying the *irritability* and *nervousness of dyspeptics*. A fluid extract of catnip, valerian, and scullcap forms an excellent agent for the cure of *nervous headache*, restlessness, and many other nervous symptoms. The expressed juice of the herb, given in doses of a table-spoonful 2 or 3 times a day, is decidedly a superior remedy in *amenorrhœa*, often restoring the menstrual secretion after other means have failed. The leaves are frequently used in fomentation as a local application to *painful and inflammatory affections*. Of the dried leaves in powder, 2 drachms may be given for a dose in

some liquid, as cold or warm water; the infusion (1 ounce of the recently dried herb to 1 pint of boiling water) may be drunk warm as freely as the stomach will permit. Specific nepeta cataria, 2 to 60 drops.

Specific Indications and Uses.—Abdominal pain, with constant flexing of the thighs, writhing, and persistent crying; colic. A remedy for children.

CATECHU (U. S. P.)—CATECHU.

"An extract prepared from the wood of *Acacia Catechu* (Linné filius) Willdenow"—(U. S. P.). (*Mimosa Catechu*).

Nat. Ord.—Leguminosæ.

COMMON NAMES: *Catechu*, *Black catechu*, *Cutch*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 95.

Botanical Source.—*Acacia Catechu* is a small-sized tree, from 15 to 20 feet high. The bark is thick, scabrous, rust-colored, slightly bitter, and exceedingly astringent; the branches are spreading, armed with strong, black, stipulary spines, and downy toward their extremities. The leaves are bipinnate; pinnae 10 to 30 pairs; leaflets 30 to 50 pairs, linear, bluntish, unequal, and auricled on the lower side of the base, and ciliated; the petiole angular, and channeled above, downy, with 1 orbicular urceolate green gland below the lowest pair, smaller ones between the two, and has 3 or 4 terminal pairs of pinnae. The spikes are axillary, 1 or 2 together, slender, cylindrical, and borne on downy stalks. The flowers are numerous, white or pale-yellow, and sessile. The calyx is downy, tubular, and 5-toothed; the teeth erect. Corolla rather longer than the calyx, 5-petaled, and glabrous. Stamens twice the length of the corolla, very numerous and distinct; anthers roundish. The ovary is green, glabrous, and shortly stipitate; the style capillary, and as long as the stamens; stigma simple. The legumes are flat, linear, thin, straight, glabrous, and contain about 6 orbicular, compressed seeds (L.).

History.—The catechu tree is common to the East Indian continent, thriving in Bengal, on the Coromandel and Malabar coasts, etc., and, according to Pereira, in Jamaica. According to Dr. Royle, the extract (catechu), is prepared by concentrating a strong aqueous decoction of the reddish inner wood, and pouring it into square clay molds to dry. Catechu is likewise obtained from the *Areca Catechu* (see *Areca*), and *Uncaria Gambier* (see below). There are several kinds of it met with in commerce, but the best are those which are the most astringent. It was named *Terra japonica* at a time when its source was unknown, the general belief being that it came from Japan.

Description and Tests.—Catechu is met with in square, round, and irregular pieces, pale-red, pale-brown, dark-brown, or blackish in color, friable, odorless, astringent, and sometimes having a sweetish after-taste. The specific gravity of catechu is 1.28 to 1.39. It is soluble in hot water, which takes up its tannic and catechuic acids, but a reddish matter is deposited as the solution cools. It is imperfectly soluble in cold water. The tannic acid of catechu is easily soluble in water and alcohol, but very slightly so in ether. Alcohol or ether dissolves its catechuic acid. Its solutions are not precipitated by alkalies. The official catechu is described as occurring "in irregular masses, containing fragments of leaves, dark-brown, brittle, somewhat porous and glossy when freshly broken. It is nearly inodorous, and has a strongly astringent and sweetish taste. If a portion of catechu be digested with 10 times its weight of alcohol, and the liquid filtered, the undissolved matter, after being dried at 100° C. (212° F.), should not exceed 15 per cent of the original weight. The tincture, diluted with 100 parts of water, acquires a green color on the addition of ferric chloride T.S. If 2 parts of catechu be boiled with 20 parts of water, a brownish-red, turbid liquid will be obtained which turns blue litmus paper red. Upon incineration, catechu should not leave more than 6 per cent of ash"—(U. S. P.). Catechu is incompatible with solutions of the pure earths, with sulphuric or hydrochloric acid, salts of aluminum, lead, copper, and with ferric salts; also with gelatin, opium, cinchona, and those salts of the vegetable alkaloids which form insoluble salts with tannin.

Chemical Composition.—Successive treatment of catechu with ether and absolute alcohol abstracts the two principal constituents, namely, from 13 to 33

per cent of crude *catechin*, also called *catechuic acid*, and from 22 to 50 per cent of a peculiar tannic acid, called *catechu-tannic acid*. Besides these are present water-soluble extractive matter, gum, and mineral substances. *Catechin* is not soluble in cold water. When pure, it forms minute, colorless crystals, which are acted on by alkalis, causing them to absorb oxygen, giving a yellow, then red, and finally a black color. Its formula is variously given as $C_{19}H_{15}O_8$ (Hlasiwetz), $C_{21}H_{15}O_8$ (Gautier), $C_{18}H_{13}O_8$ (Rochleder), $C_{21}H_{15}O_8 + 5H_2O$ (Liebermann and Tauchert). When subjected to dry distillation, it yields *pyrocatechin* ($C_6H_4O_2$), while *phloroglucin* and *protocatechuic acid* are produced by fusing it with caustic potash. By the action of sulphuric acid, *catechuretine* is produced.

The *catechu-tannic acid* of catechu, sometimes termed *mimnotannic acid* and *catechu-red*, differs from ordinary tannic acid by giving a greenish-gray precipitate with the iron salts, by not precipitating a solution of tartar emetic, and by not furnishing pyrogallic acid on exposure to heat. It is an amorphous, deep-red powder, dissolving in alcohol, alcoholized ether, and water, but little soluble in absolute ether, and is regarded as an anhydrid of catechin.

Quercetin was obtained from the aqueous solution of catechu by means of ether, by Löwe, in 1873.

Pyrocatechin ($C_6H_4O_2$), or *catechol*, may be obtained from many tannins and extracts by means of destructive distillation. It forms short, prismatic crystals, readily soluble in water, ether, and alcohol. Ferric chloride colors its solution in water a deep green, which, when treated with sodium bicarbonate, ammonia, or tartaric acid, changes to a violet hue. Catechol fuses at $104^\circ C.$ ($219.2^\circ F.$). Its boiling point is $245^\circ C.$ ($473^\circ F.$). Its methylic ether is *guaiacol*. Certain gum-resins, resins, and tannins, when fused with caustic potash, produce *protocatechuic acid* ($C_7H_5O_4$) (dioxibenzoic acid). It forms shining, acicular crystals, or may form scales, readily soluble in hot water, alcohol, and ether. When heated above $199^\circ C.$ ($390.2^\circ F.$) it is resolved into *pyrocatechin* and carbonic acid gas. When treated with ferric chloride its aqueous solution gives a deep-green color, changing successively to blue and red by sal soda solution much diluted.

Action, Medical Uses, and Dosage.—Catechu possesses strong astringent properties. It is used for arresting mucous discharges when excessive, for removing relaxation or congestion of mucous membranes, and for checking hemorrhages. In chronic diarrhœa, chronic catarrh, colliquative diarrhœa, and chronic dysentery, it has proved beneficial, especially when combined with opium. As a local application, it is a valuable agent for removing *cynanche tonsillaris*, aphthous ulcerations of the mouth, elongation of the uvula, and relaxation and congestion of the mucous membrane of the fauces, especially of the kind to which public singers are subject; it is also useful in congestion, tenderness and sponginess of the gums, particularly when the result of mercurial ptyalism. The tincture of catechu is often beneficial in fissure of the nipples, when applied twice a day with a fine hair pencil. An ointment composed of 4 ounces of catechu, 9 drachms of alum, 4 ounces of white resin, and 10 fluid ounces of olive oil, with a sufficient quantity of water, is in great repute in India as an application to ulcers (Thomson, *Lond. Dis.*). Chronic and phagedenic ulcers are frequently benefited by the application of catechu to them. Chronic gonorrhœa, old gleet, and fluor albus, as well as hemorrhage from the nose and other parts, have been cured by the local application of an aqueous solution of catechu. Powdered catechu may be given in a dose of from 5 to 20 grains, or more, repeated as often as required; it may be administered in pill form, in syrup, or in gum mucilage. The dose of the tincture is from 20 minims to $\frac{1}{2}$ fluid ounce. Dr. E. Hopkins states that catechu is not incompatible with opium and quinine, as no precipitate ensues when their respective solutions are united. He recommends, in diarrhœa, a compound of catechu 10 grains, opium 1 grain, sulphate of quinine 2 grains; mix, and make into 1 or 2 powders, according to the urgency of the case. CATECHU PALLIDUM (see below), has similar properties, but is less astringent.

Related Drugs.—CATECHU PALLIDUM. *Pale catechu* (Catechu of Br. Ph.).—This is also known as *Terra Japonica*, *Gambir*, *Gambier*, and *Gambeer*. Pale catechu is the official catechu of the *British Pharmacopœia*, and one of the official kinds of the *German Pharmacopœia*. It is extracted from the young leaves and shoots of *Uncaria Gambier*, Roxburgh (*Nauclea Gambier*, Hunter). *Nat. Ord.*: Rubiaceæ. This is a climbing plant bearing pink flowers, and grows in Sumatra, Ceylon, and in the countries bordering the straits of Malacca. At Singapore it is

extensively cultivated. A species thought to be a variety, *Uncaria acida*, Roxburgh, also furnishes a portion of pale catechu. Gambier is prepared by boiling the fresh young twigs and leaves for 1 hour, after which they are taken out and placed in a trough which allows the decoction to flow back into the boiling pan, and the liquor from the exhausted shoots and leaves is squeezed out by hand. The fluid is then evaporated to a thin, syrupy consistence, and dipped into vessels to cool, and instead of stirring round and round, the operator passes a soft piece of wood in and out of the liquid, in a sloping manner. This, he asserts, will cause it to thicken when ordinary stirring will have no effect on it. It is then poured into shallow, rectangular molds, and allowed to harden sufficiently to be cut into cubical blocks to be dried in a shady situation (see *Pharmacographia*). Gambier is an earthy-appearing mass of pale-brown color. It occurs in small cubes, or may come in irregular, compact masses. It is lighter in color than cutch, which it resembles, and when broken (for it is porous, dry, and friable), it presents an irregular surface of an earthy, brownish-gray hue, interspersed with darker streaks. It is odorless, but has a bitter, astringent, and afterwards sweetish taste. The microscope shows it to be made up of minute, crystalline needles. It dissolves in alcohol, giving a deep-brown solution. Water does not dissolve it wholly, and with hot water a turbid mixture is produced. Impurities to the extent of 15 per cent of the whole weight are allowed by the *German Pharmacopœia*. The same work limits its ash to not more than 6 per cent. Its chemical composition agrees with that of cutch (catechu), the proportion of tannin being less than in the latter. The coloring principle is *quercetin* and the chief constituent is *catechin*, which gives to it a crystalline appearance. *Quinovic acid* is probably present in gambir, having been found in other species of *Nauclea*. It contains from 25 to 38 per cent of tannin, and from 20 to 29 per cent of catechin. The ash consists largely of calcium and magnesium carbonates (*Pharmacographia*). Prof. Trimble (*Am. Jour. Pharm.*, 1888) making a comparative determination of catechin, catechu-tannic acid and other constituents in 3 representative samples each, of cutch and of gambier, finds a decidedly higher percentage of available tannin in gambier than in cutch. He therefore recommends the official use of gambier in preference to cutch for several reasons: Gambier, as he finds, has more available astringency, and being put up in the form of cubes, can not be so easily adulterated, and is not liable to contain mordants added for the use of dyes.

CAULOPHYLLUM (U. S. P.)—CAULOPHYLLUM.

"The rhizome and roots of *Caulophyllum thalictroides* (Linné), Michaux"—(U. S. P.). (*Leontice thalictroides*, Linné).

Nat. Ord.—Berberidaceæ.

COMMON NAMES: *Blue cohosh*, *Squaw-root*, *Pappoose-root*.

ILLUSTRATION: Lloyd's *Drugs and Med. of N. A.*, Vol. II.

Botanical Source.—This plant is a smooth, glaucous plant, purple when young, with a high, round stem, from 1 to 3 feet in height, simple from knotted

Caulophyllum thalictroides.

and matted root-stalks, dividing above into 2 parts, 1 of which is a triternate leaf-stalk, the other bears a biternate leaf and a racemose panicle of small, yellowish-green flowers. The leaves are biternate and triternate. The petiole is trifid, supporting 9 leaflets. The leaflets are oval, petiolate, and unequally lobed, the terminal one equally 3-lobed, paler beneath, and from 2 to 3 inches long. The panicle is small, and shorter than the leaves. The pericarps are thin, caducous, dark-blue, and resemble berries on thick stipes. Seeds 1 or 2, erect, globose, about the size of a large pea (W.—G.).

History.—This drug is one of our oldest indigenous Eclectic remedies. The Algonkin name (*cohosh*) is generally supposed to have been applied to this plant by the natives, but according to the statement of Mr. W. R. Gerard, this is hardly probable, as the native term, "applied by the whites to several plants, smooth in all their parts, means 'it is rough' (with hairs)." Among the Montagnais of Canada the name *cohosh* is applied to the bristly fruit of *Ribes lacustre*. (See *D. & M. of N. A.*) Still, there is

no doubt that the plant was later known to the American Indians, in common with *Cimicifuga racemosa*, *Actæa alba*, and *Actæa rubra* var. *spicata*, as cohosh. The true common name of the plant is *blue cohosh*, though it is known also in various parts of the country as *pappoose-root* (Smith), *squaw-root* (Smith), *false cohosh* (Eaton), and *blueberry*. Both Pursh (1814) and Barton (1818) call it cohosh, and state that it was known as such among the natives. The plant was introduced into medicine as blue cohosh by Rafinesque, in 1828, though it is but just to say that the Indian uses of the plant were first made known through an irregular publication entitled "*Medical Facts*," issued in Cincinnati, in 1813, by Peter Smith, an advertising "Indian herb doctor;" and, it is to Smith that Rafinesque refers as an authority on the subject. The first published botanical record of the blue cohosh is by Gronovius (1739), who received the plant from Clayton, a Virginian botanist, and the second by Cadwallader Colden (1743), an American botanist, afterward distinguished as governor of New York State. Its present botanical name (*Caulophyllum*) was given it in 1803 by the elder Michaux, who believed the genus to differ sufficiently from the European *Leonice*, with which it had been classed, to entitle it to a generic rank of which only the one species is now known, which is a native of America, and is found also in Japan. The term *Caulophyllum* is derived from two Greek words—*kaulos*, stem; and *phyllon*, leaf; hence, stem-leaf, so called because the leaves terminate in such a manner as to give them the appearance of being a mere continuation of the stem. Blue cohosh is widely distributed throughout this country extending from New Brunswick to the southern limits of the Appalachian system of mountains, and westward to the Mississippi valley. Contrary to published statements it is not found in low, moist grounds, swamps and marshes, along sea-coasts and on prairie lands and irrigated islands, but grows in rich, shady woods, and deep loam, in hilly and mountainous districts. It is plentiful along the Alleghany mountains, but it is not found in the adjacent lowlands in the southern states. *Caulophyllum* is a handsome plant of a peculiar bluish-green color. It blossoms in April and May and matures its fruit in August. A decoction of the roasted ripened seeds is said to resemble coffee. Although *caulophyllum* was first introduced by Peter Smith as early as 1813 and endorsed by Rafinesque (1828) and the botanics, there was but little call for it, except in domestic medicine for making infusions and decoctions, until 1852, when Prof. King, who first became acquainted with the drug in 1836, brought it out in his first edition of the *American Dispensatory*, giving a description of it and its uses, and introducing some preparations of it. From that time until the present day it has been in increasing demand in Eclectic practice, and has been adopted by the Homœopaths, though it is still largely ignored by the "regulars." Prof. E. M. Hale, M. D., of Chicago, states that *caulophyllum* was introduced to the Homœopaths by Prof. B. L. Hill, at one time Professor of Surgery in the Eclectic Medical Institute, of Cincinnati, O., in his lectures on obstetrics and gynecology before the Homœopathic College, at Cleveland, O. At the same time he introduced to them *hydrastis*, *cimicifuga* and other Eclectic drugs. Among the early preparations of this drug were the fluid extract of *caulophyllum*, compound tincture of *caulophyllum*, and the compound tincture of *mitchella* (mother's cordial), all exclusively Eclectic products. Blue cohosh partially yields its virtues to hot water and glycerin, and fully to alcohol. It may be employed in decoction, or the specific *caulophyllum*, which is reliable and more convenient, may be used. In purchasing, care must be taken that this root is not mixed with other roots, especially those of the *Hydrastis canadensis*, with which the pressed and wrapped article prepared for sale is apt to be associated. *Caulophyllin* added to drastic purgatives, as aloes, *podophyllin*, etc., will entirely prevent or relieve the tormina attending their action.

Description.—"Rhizome of horizontal growth, about 10 Cm. (4 inches) long, and about 6 to 10 Mm. ($\frac{1}{4}$ to $\frac{1}{2}$ inch) thick, bent; on the upper side with broad, concave stem-scars, and short, knotty branches; externally grayish-brown, internally whitish, tough and woody. Roots numerous, matted, about 10 Cm. (4 inches) long, and 1 Mm. ($\frac{1}{16}$ inch) thick, rather tough, nearly inodorous; taste sweetish, slightly bitter and somewhat acrid"—(*U. S. P.*).

Chemical Composition.—The most detailed chemical analysis to date of *caulophyllum* was made, in 1864, by Mr. A. E. Ebert. He found it to contain

albumin, starch, gum, coloring matters, calcium phosphate and sulphate, salts of iron, potassium and magnesium, phosphoric acid, silica, and 2 resins, one soluble in alcohol and ether, and the other not soluble in ether, and "a substance similar to saponin." The latter substance was, in 1863, identified and called *saponin* by Prof. F. F. Mayer, who claims also to have obtained a colorless alkaloid. This alkaloid Mr. Ebert failed to find, and inferred that Prof. Mayer's analysis was made with a drug adulterated with hydrastis, or some other alkaloid-yielding plants. He found also that the only substance of interest was the resinous, saponin-like body. Prof. J. U. Lloyd agrees with him in the main as to his analysis and especially with the latter's statement that the "substance similar to saponin" was the characteristic principle of the plant. This amorphous substance found by Mr. Ebert was at first sweetish, and then acrid to the taste, and irritated the nostrils, provoking sneezing. It was soluble in alcohol, both strong and dilute, and in alkaline aqueous fluids. It remained, however, for Prof. Lloyd to obtain this characteristic principle in a pure, crystalline form, for the white amorphous precipitate found by Mr. Ebert contained much foreign matter that was entirely eliminated, in Prof. Lloyd's experiments, by repeated crystallization. To this principle, which, by the way, is a glucosid, Prof. Lloyd applied the name *leontin*—a name derived from the old Greek botanical name *Leontice* (lion's foot), applied to the genus (*caulophyllum*) by Linnæus. This name, *leontin*, was given to it because the name *caulophyllin*, which could most appropriately be given it, had been applied already to the resinoid of *caulophyllum*.

LEONTIN, as obtained by Prof. Lloyd's process, is a glucosid, occurring in pure, snow-white, feathery, or silky crystals, resembling quinine. It is slightly soluble in cold alcohol, very soluble in boiling alcohol, from which it crystallizes upon cooling. It is slightly soluble in anhydrous alcohol, very soluble in boiling anhydrous alcohol, from which it also crystallizes upon cooling, the most perfect crystals being obtained from absolute alcohol. In sulphuric acid, both cold and boiling, its solubility is similar to that in alcohol. In chloroform it is practically insoluble. It is insoluble in water, and upon the addition of water to the alcoholic solution, immediate precipitation is the result. Acids precipitate it and alter its character, while alkaline aqueous solutions dissolve it freely and perfectly. *Leontin* is tasteless, but owing to the alkalinity of the saliva, it slowly dissolves, producing an acrid after-taste. Alcoholic solutions of it are acrid to the taste, while the alkaline aqueous solution is extremely acrid and irritating to the mouth and fauces, and for this reason should be administered in syrup, or in sweetened water, which somewhat obtunds these sensations. While odorless, the dust is acrid, producing irritation of the nostrils. *Leontin*, even in dilute solution, forms much froth when shaken. Prof. Lloyd has further shown that while Prof. Mayer did not obtain an alkaloid from *caulophyllum*, (which he claims to have done and named *caulophylline*), such an alkaloid does exist, and that he (Lloyd) has separated it as an amorphous, glassy substance, colorless, tasteless, and odorless, freely soluble in alcohol, and quite soluble in water. It does not possess the characteristics of *caulophyllum*, nor does it have any sensible properties. The name *caulophyllin* applied by Mayer must not be confounded with that of the resinoid, *caulophyllin*.

Shortly after 1835, when Prof. John King discovered podophyllin, macrotin, hydrastin, etc., he also brought forth the substance now known in commerce as *caulophyllin*. It was in great demand among Eclectics in times past, and is still sold in considerable quantities. But like nearly all of the so-called concentrations and resinoids of early Eclectic preparation, while they were better agents than preceding pharmacal products, yet at the present time they are too uncertain in composition and medicinal value, to hold a leading place among our more modern therapeutic preparations. The current statement in medical publications that *caulophyllin* is obtained by precipitation from a strong alcoholic tincture with water is, according to Prof. Lloyd, erroneous, as there is no evidence from manufacturers to support it. As prepared by Lloyd, whose process is given in "*Drugs and Medicines of North America*," *caulophyllin* is a powder of a grayish or brown color, and possesses the characteristic taste of the crude drug. The preparation known as *Lloyd's Leontin*, is a one per cent solution of the white crystalline emmenagogue principle above described.

Action, Medical Uses, and Dosage.—Of caulophyllum, Rafinesque states that "as a powerful emmenagogue it promotes delivery, menstruation, and dropical discharges," and that "it was employed by the Indians and their imitators for *rheumatism, dropsy, colic, sore throat, cramp, hiccough, epilepsy, hysterics, inflammation of the uterus, etc.*" Prof. King first employed blue cohosh for its beneficial influence on abnormalities of the mucous tissues, using it for *aphthous stomatitis* in decoction, alone or combined with *hydrastis*. Prof. Scudder believed that this agent exerted its influence through the hypogastric plexus, thus affecting the circulation, nutrition, and functions of the reproductive apparatus.

Blue cohosh is reputed antispasmodic, emmenagogue, and parturifacient, besides being diuretic, diaphoretic, and expectorant. Its use as a parturient originated in the custom of the Indian squaws of employing a decoction of the root for 2 or 3 weeks previous to labor to facilitate *child-birth*. This became known to the whites through Smith's publication. There is no doubt but that caulophyllum has a decided action upon the gravid uterus. During labor it relieves *false pains* and coördinates muscular contractions, at the same time increasing their power. Like *macrotys*, it is a better oxytocic than *ergot*. Unlike the latter agent it stimulates normal contraction instead of inducing spasmodic uterine action. It is most valuable in those cases where delay is due to debility, fatigue, or lack of uterine nervous energy, and for deficient contractions where the tissues feel full, as if congested. As a *partus preparator*, blue cohosh has enjoyed a well-merited reputation. When used by delicate women, or those who experience prolonged and painful labors, for several weeks previous to confinement, it gives tone and vigor to all the parts engaged in the accouchement, facilitating its progress, and relieving much suffering. Prof. Hale testifies that women who have taken caulophyllum previous to confinement, have overrun their time from 10 to 12 days, but all had very easy labors and made good recoveries. It is a good remedy for *after-pains*, especially when spasmodic in character. Caulophyllin has also been used for this purpose. It is a remedy for *hour-glass contraction* and for *spurious labor-pains*. Blue cohosh acts as an antiabortive by relieving the irritation upon which the trouble depends. King states that for this purpose it is fully equal to *viburnum*.

As a gynecian remedy it has been employed to relieve *irritation of the reproductive organs* as if dependent on congestion. It controls chronic inflammatory states of these organs and gives tone in cases of debility. In the sexual disorders of the female it is indicated by tenderness and pain in the uterus, in debilitated patients. It has been very successfully used in cases of *hysteria* to overcome the attack, and to relieve *ovarian, or mammary pain, or irritation* when accompanying that disorder. *Chronic corporeal, or cervical endometritis, metritis, ovaritis, ovariagia, uterine leucorrhœa, amenorrhœa, and dysmenorrhœa*, are conditions in which it has been most successfully employed. It has an established reputation as a remedy for *rheumatism of the uterus*, with nervous excitement, for *uterine cramps* attending menstruation, and for *menorrhagia*, depending on *uterine subinvolution*.

As an antispasmodic it has been employed in *chorea* and *epilepsy* due to diseased states of the sexual organs, but with varying results. It is better suited for *spasmodic intestinal affections*, as *flatulent* and *spasmodic colic*, and *cramps*. It is not without value in *obstinate singultus*. Its antispasmodic effects are permanent.

By lessening irritation it has been serviceable in *cystitis, urethritis, chronic nephritis, and albuminuria*. *Spasmodic retention of urine* is relieved by it. It is a good remedy for some cases of *rheumatism*, though not so valuable as *macrotys*. It effectually overcomes rheumatoid conditions of the uterus and of the stomach—in the latter instance when crampy pains follow the ingestion of food. While valuable in all chronic cases of *muscular rheumatism*, it is especially adapted to *articular rheumatism*, particularly when confined to the smaller joints, as of the toes and fingers. It is a remedy for *asthenic plethora*, and for rheumatic pains accompanying that condition. Associated with testicular support, it favorably influences *orchialgia*. By its sedative action it is valuable in some cases of *insomnia*, and has been suggested as a remedy for *bronchitis* and *catarrhal pneumonia*. It is also a remedy for *gastric nausea* and *vomiting*. Dose of the infusion (root ʒj to aqua Oj), from 1 to 3 ounces, every 3 or 4 hours; of specific caulophyllum, from 3 to 10 drops; of caulophyllin, from 2 to 4 grains.

Lloyd's Leontin (the 1 per cent solution of the emmenagogue principle of blue cohosh) has been very successfully employed in *amenorrhœa*, *dysmenorrhœa*, and *chlorosis*. The dose ranges from 5 to 15 drops in syrup or sweetened water.

Specific Indications and Uses.—The specific indications for caulophyllum are uterine pain, with fullness, weight, and pain in the legs; fullness of tissues as if congested; debility (irritability) of the nervous system, with impaired muscular power; spasmodic muscular pains; articular pain; rheumatic pains of asthenic plethora; epigastric and umbilical colicky pains; dull frontal headache; great thirst; as an oxytocic; to relieve false pains and uterine irritability; sexual debility, with excitability; spasmodic uterine contractions; dysmenorrhœa; irregular menstruation; crampy pains in stomach and bowels after eating; pain in toes and fingers not due to tissue changes.

Related Drug.—*Stylosanthes elatior*, Swartz. *Pencil flower*. United States. Reputed of value in relieving abdominal and uterine pains during pregnancy, and is said to be a tonic parturient.

CEANOTHUS.—RED-ROOT.

The root, root-bark, and leaves of *Ceanothus americanus*, Linné.

Nat. Ord.—Rhamnaceæ.

COMMON NAMES: *Red-root*, *New Jersey tea*, *Wild snowball*.

Botanical Source.—This plant has a large root, with a red or brown epidermis, containing many small,

Fig. 63.

Ceanothus americanus.

white veins, and tolerably thick; body of the root dark-red. The stems are from 2 to 4 feet high, slender, suffrutescent, with many reddish, round, smooth branches, the younger ones pubescent. The leaves are ovate or oblong-ovate, acuminate, serrate, 3-veined, rather smooth above, downy, with soft, reddish hairs beneath, and often heart-shaped at base. The flowers are minute, white, in long, crowded panicles from the axils of the upper leaves. Calyx 5-cleft, campanulate, cut round after flowering, with the base permanent and adhering to the fruit. Petals 5, saccate-arched, with long, spreading claws. Stamens 5, exserted, inclosed in the curiously vaulted corolla; anthers ovate, 2 celled; ovary, 3-angled. Fruit dry, obtusely triangular, 3-celled, loculicidal, with papery valves; cells 1-seeded; seed convex outside, concave within (G.—W.).

History.—*Ceanothus americanus* is indigenous to the United States, and is very abundant in the West; it grows in dry woodlands, barrens, etc., flowering from June to August. The leaves are astringent and slightly bitter, and have been used as a substitute for tea, to which they have a strong resemblance when dried, both in taste and odor. The root is the medicinal part, and has a taste and smell somewhat resembling those of the peach leaf. It has been occasionally used for coloring. Water extracts its active principle.

Description.—Red-root is a long, cylindrical, thick, irregularly contorted, branching root, with either a simple or branched head, with knotty tubercles. Its surface is finely corrugated, and of a rusty-brown color. The bark is thin, and breaks with a granular fracture; the wood, light brownish-red, and tough. To the taste red-root is astringent and bitter, but has no odor.

Chemical Composition.—The leaves are said to contain tannin, a soft resin, a bitter extractive, a greenish coloring matter almost identical in color and taste with green tea, gum, a volatile substance, lignin, and a principle called *ceanothine*, but which does not appear to exert as much therapeutical value as the infusion or fluid extract of the root-bark. When purified, *ceanothine* is white; its odor and taste is similar to that of green tea; it is soluble in water, but insoluble in alcohol, ether, and carbon disulphide. Chloroform is its best solvent. Clinch (*Amer. Jour. Pharm.*, 1884) found in the leaves a volatile oil. The bark contains considerable tannin and *ceanothine*.

F. C. Gerlach (*Amer. Jour. Pharm.*, 1891) found ceanothus-red, tannin, volatile oil, gallic acid, resin, vegetable wax, fixed oil, starch, saccharose, glucose, mucilage, albuminoids, calcium oxalate, and the alkaloid *ceanothine*, which he found to resemble caffeine in not forming salts, but differing in not being precipitated with Mayer's reagent (*A. P. A. Proc.*, 1892).

Action, Medical Uses, and Dosage.—Astringent, expectorant, sedative, antispasmodic, and antisyphilitic. It is used in *gonorrhœa*, *dysentery*, *asthma*, *chronic bronchitis*, *whooping-cough*, and other *pulmonary affections*. Dose of a strong decoction, 1 tablespoonful 3 or 4 times a day. It has likewise been successfully used as a wash and gargle in the *aphthæ* of children, *sore mouth* subsequent to *fever*, and in *ulceration of the fauces* attendant on *scarlatina*.

Besides the old uses, as given above, ceanothus has been found to be a useful gastric, hepatic, and splenic stimulant, and it is in splenic troubles that its action is most favorable. Scudder (*Spec. Med.*), states that it is indicated by *splenic enlargement*, with *sallow*, *doughy skin*, and *expressionless face*. Webster gives as indications, *deep-seated splenic pain*, though no enlargement be detectable, and for the *pain of splenic hypertrophy*, as well as for *sympathetic, painful conditions* depending upon splenic wrong. Its action is compared to that of *carduus marianus*, influencing the hepatic, and more so the splenic vessels, overcoming congestion. *Hypertrophy of the spleen* and *splenitis* of malarial origin are met with it. The cases of splenitis to which it is specially adapted are not acute, but rather sub-acute, after the active symptoms have passed, and when pressure does not markedly aggravate the pain. It was much used during the Civil War for *malarial splenitis*. Copious *catarrhal profluvia* in non-inflammatory conditions are benefited by its astringency. For hepatic and splenic disorders the tincture of the leaves is preferred. Dose: Strong decoction, fss 3 times a day; specific ceanothus, 1 to 10 drops.

Specific Indications and Uses.—Enlarged spleen; *sallow*, *doughy skin*; *expressionless countenance*; non-inflammatory, *catarrhal states*, with *profuse secretion*.

Related Species.—*Ceanothus ovalis*, Bigelow. United States, Vermont to Rocky Mountains. Has oval leaves, and is probably similar to above species.

Ceanothus reclinatus, De Candolle. Mexico and West Indies. Used by the natives in *gonorrhœa*, *syphilis*, *dysentery*, *ulceration of the mouth and fauces*, and *cancer*.

Ceanothus azureus, Desfontaines, and *Ceanothus cæruleus*, Lagasca. Mexico. Febrifuge.

CELASTRUS.—FALSE BITTERSWEET.

The bark of the root and the bark of *Celastrus scandens*, Linné.

Nat. Ord.—Celastraceæ.

COMMON NAMES: *Staff-tree*, *Climbing staff-tree*, *Staff-vine*, *False bittersweet*, *Climbing bittersweet*, *Waxwork*, *Fever-twig*.

Botanical Source.—This plant is a climbing, indigenous shrub, with a woody, twining stem, without thorns or prickles. The leaves are thin, oblong, acuminate, serrate, alternate, stipulate, petiolate, and smooth; the racemes small, terminal, and axillary; the flowers are greenish-white, or yellowish-white, fragrant, and dioecious. Calyx flat, 5-lobed; corolla spreading, of 5 sessile petals; capsule obtusely 3-angled, 3-celled, and berry-like; valves bearing the partitions on their centers; stamens standing around a glandular, 5-toothed disk; style thick; stigma 3-cleft. The seeds, which are covered with a scarlet aril, number 1 or 2 in each cell (G.—W.).

History.—This plant grows in woods and thickets, from Canada to the Carolinas, creeping on hedges and rocks, or twining about other trees, or each other, and ascending to a great height. It flowers in June and bears a scarlet berry, which remains through the winter. The plant thrives most luxuriously in a rich, damp soil. The root is very long, creeping, woody, of a bright-orange color, about

Celastrus scandens.

$\frac{1}{2}$ inch in thickness, with a thick red, or yellowish-red bark, which is the medicinal part. On account of the similarity of name, bittersweet, the plant has been confounded with the *Solanum Dulcamara*, from which, however, it essentially differs in appearance and therapeutic action. The bark has a bitter, afterward sweetish, rather nauseous taste, and imparts its medicinal properties to water.

Description.—The root-bark occurs in nearly smooth quills, orange-brown externally; whitish and marked with fine striæ internally. A second layer of an orange-red hue is exposed on the removal of the somewhat tough outer bark. The stem-bark resembles the above, except that its outer layer has an ashen-gray or brownish-gray color.

Chemical Composition.—Wayne (1872) obtained a white crystalline principle to which the name *celastrin* was given. Bernhard (*Amer. Jour. Pharm.*, 1882) found the bark to contain starch, gum, sugar, coloring material, volatile oil, two resins, one acid and the other neutral, and a body resembling caoutchouc. Mr. Jacob Hoch (1892), failed to find any volatile constituents (*A. P. A.*, 1892). The coloring matter of *Celastrus scandens* was investigated by Dr. Keller, who defined its chemical relation to the vegetable coloring matters, xanthin and carotin (*Amer. Jour. Pharm.*, 1896).

Action, Medical Uses, and Dosage.—Alterative, diaphoretic, and diuretic, with some narcotic powers. Used in *scrofula*, *secondary syphilis*, *chronic hepatic affections*, *cutaneous affections*, *leucorrhœa*, *rheumatism*, and *obstructed menstruation*. Externally an ointment has been successfully employed in *inflamed and indurated breasts of nurses*, in *pruritis vulvæ*, *burns*, *excoriations*, etc. Dose of the decoction, from 2 to 4 fluid ounces, 3 times a day; of the extract, from 5 to 10 grains.

CEPHALANTHUS.—BUTTONBUSH.

The bark of *Cephalanthus occidentalis*, Linné.

Nat. Ord.—Rubiaceæ.

COMMON NAMES: *Buttonbush*, *Buttonwood*, *Pond dogwood*, *Crane willow*, *Globe flower*.

Botanical Source.—This plant is a handsome shrub growing from 6 to 12 feet or more high, the bark being mostly rough on the stem and smooth on the branches. The leaves are opposite or in whorls of 3, oval, acuminate, entire, smooth, spreading, petioled, with short, intervening stipules, and from 3 to 5 inches by 2 to 3. The flowers are white, terminal, in spherical heads about an inch in diameter, resembling the globular inflorescence of the sycamore (*Platanus occidentalis*). Peduncles long; corolla tubular, slender, and 4-cleft; calyx tube inversely pyramidal, the limb 4-toothed; stamens 4; anthers yellow; style thread-form, much protruded; stigma capitate, yellow. The fruit consists of small, hard, and dry capsules, inversely pyramidal, 2 to 4-celled, separating from the base upward into 2 or 4 closed 1-seeded portions (G.—W.).

History and Description.—Buttonbush is indigenous to the United States, and is found in damp places, along the margins of rivers, ponds, etc., flowering from June to September. The bark is the part used, and possesses much bitterness. Water or alcohol takes up its virtues. Buttonbush bark occurs in market as short, curved pieces of a smooth, grayish-brown color marked with fine striæ externally. The smooth and white inner bark is tough, and changes to a pale, rusty-brown color. Old bark has sometimes a fissured, ashen-gray, corky layer upon the surface. It has a bitterish, sub-astringent taste, but no odor.

Chemical Composition.—Analysis has shown the bark to contain starch, sugar, gum, fatty matter, several resins, tannin, a saponin-like body, and an amorphous, bitter constituent readily soluble in both water and alcohol. A crystalline, fluorescent body has been obtained by precipitation with acetate and subacetate of lead. These acicular crystals are dissolved by alcohol, ether, and water (Hattan, *Amer. Jour. Pharm.*, Vol. XLV).

Mr. Edo Claassen has obtained three bodies from the bark, *cephalanthin*, *cephaletin*, and *cephalin*. The latter occurs as warty crystals, and is thought to be a glucosid, splitting up into glucose and *cephaletin* on evaporating the solution. *Cephalin* is in yellowish-white needles, strongly-refracting, acid in reaction, and otherwise tasteless. It is insoluble in petroleum ether, very sparingly soluble

in cold water, more soluble in hot water, and dissolving with greater ease in alcohol, ether, benzol, chloroform, and acetic acid. This body is strongly fluorescent in aqueous, alcoholic, and alkaline solutions, all well diluted. Even so minute a trace as 1 part in 2,000,000 of water exhibits this property, and if an alkali be added the blue coloration will be noticeable in a dilution of 1 to 20,000,000. The concentrated alkaline solution has a lemon-yellow color (*Proc. A. P. A.*, 1892).

Action, Medical Uses, and Dosage.—Tonic, febrifuge, aperient, and diuretic. The bark has been used with much success in *intermittent* and *remittent fevers*; and the inner bark of the root forms an agreeable bitter, which is often employed in *coughs*, and as a diuretic in *gravel*. The plant deserves further investigation. Tincture, 10 to 30 drops; infusion, fl̄ss to fl̄ʒi.

Cephalanthin is, according to Kobert (1892), distinctly poisonous to both cold and warm-blooded animals, producing emesis, spasms, and paralysis. It destroys the blood corpuscles, converting them into methæmoglobin and oxyhæmoglobin.

Related Species.—*Sarcocephalus esculentus*, Afzelius. Senegambia and Sierra Leone furnish this plant, which is known in its habitat as the *doundake*. The bark, under the names *Quinquina Africaine* and *Kina du Rio Nunez*, is employed by the negroes as a febrifuge. More properly it is an astringent tonic, and as such is useful in the *anemic state* following *typhoids*, and as a remedy for *loss of appetite*, and for *atonic dyspepsia*. No alkaloid is present, according to Heckel and Schlagdenhaufen, but its virtues seem to depend upon three resinous principles—an orange-yellow bitter soluble in water, alcohol, and solution of potassa; a pale-yellow body insoluble in water, but soluble in potassa solution; and the third insoluble in alcohol and water, but dissolving in the potassa solution.

CERA ALBA (U. S. P.)—WHITE WAX.

"Yellow wax bleached"—(U. S. P.) (see under *Cera Flava*).

CERA FLAVA (U. S. P.)—YELLOW WAX.

"A peculiar, concrete substance, prepared by *Apis mellifica*, Linné"—(U. S. P.).

Class: Insecta. *Order*: Hymenoptera.

Source, History, and Preparation.—Wax is a substance which exists in small quantities in various plants. It is chiefly obtained, however, through the agency of the common bee (*Apis mellifica*), which forms cells, in which its food and ova are contained. It is a natural product of the insect, being secreted upon the abdominal scales or rings. The wax produced by the bee is the official article, of which there are two kinds, yellow wax and white wax.

YELLOW WAX is procured directly from the comb, which, after having been deprived of its honey, is fused in boiling water, strained, again fused, and poured into appropriate vessels of various sizes.

WHITE WAX is prepared by exposing ribbons of yellow wax to air, sunshine, and moisture, for one or two weeks, or more, according to the weather, when it loses its color, nearly all of its odor, and becomes yellowish-white. To bring about this effect, it must be turned every day, and watered from time to time. The wax is then remelted, reribboned, and rebleached; it is subsequently refined by melting in water acidulated with sulphuric acid. When finished, it is cut or cast into flat, round cakes, to which a little spermaceti is generally added to improve the color (C.). Chlorine will also decolorize wax, but changes its character, causing it, when burned, to evolve irritating vapors of hydrochloric acid.

Description and Chemical Composition.—CERA ALBA, *White wax*. "A yellowish-white solid, somewhat translucent in thin layers, having a slightly rancid odor, and an insipid taste. Specific gravity: 0.965 to 0.975 at 15° C. (59° F.). Melting point about 65° C. (149° F.). In other respects white wax has the characteristics of, and should respond to the reactions and tests given under yellow wax (see *Cera Flava*)"—(U. S. P.). It readily dissolves in fixed and volatile oils, and combines by fusion with fats and resins; boiled with caustic alkaline solutions, it is imperfectly saponified.

CERA FLAVA.—*Yellow wax*. "A yellowish to brownish-yellow solid, having an agreeable, honey-like odor, and a faint, balsamic taste. Specific gravity:

0.955 to 0.967 at 15° C. (59° F.). Melting point: 63° to 64° C. (145.4° to 147.2° F.). It is brittle when cold, and when broken presents a dull, granular, not crystalline fracture. By the heat of the hand it becomes plastic. Yellow wax is insoluble in water, sparingly soluble in cold alcohol, but almost completely in boiling alcohol. It is completely soluble in ether, chloroform, and in fixed and volatile oils; partially soluble in cold benzol or carbon disulphide, and completely in these liquids at a temperature of 25° to 30° C. (77° to 86° F.)—(U. S. P.). Wax possesses considerable firmness and tenacity, though somewhat soapy, but not greasy to the touch. At a high temperature it boils, and in close vessels distills over with little alteration; at a red heat its vapor inflames, burning with a dense white brightness. Boiling alcohol dissolves about 20 per cent of it (cerotic acid), but deposits it upon cooling almost completely. Yellow wax is largely a mixture of 3 substances: *Myricin*, or *myricyl palmitate* ($C_{16}H_{31}O_2 \cdot C_{30}H_{61}$), which is the principal constituent, not soluble in boiling alcohol, and having its fusing point at 72° C. (161.6° F.); *cerin*, or *cerotic acid*, ($C_{27}H_{54}O_2$) (Brodie), extractible from wax by boiling alcohol, fusing at 78° C. (172.4° F.); and *cerolein*, an acid substance, soluble in alcohol, to which are also due the color and flavor of wax.

Adulterations and Tests.—Both yellow and white wax are liable to adulterations. Resin may be suspected by the fracture being smooth and shining, instead of granular; also by its solubility in cold alcohol. Insoluble mineral and organic substances, like clay, yellow ochre, starch, etc., may be separated by dissolving the wax in chloroform, whereby these substances remain behind. However, this kind of clumsy adulteration is not now liable to occur. Tallow and suet reduce the melting point of wax, and impart an unpleasant odor when melted. Fatty acids, e. g., stearic acid, may also be detected by the formation of a granular precipitate of calcium soap, when the chloroformic solution is shaken with lime water. If the wax contains starch, boil it in water, and add tincture of iodine to it, which will produce a blue color. (For *Myrtle wax* see *Myrica cerifera*). Paraffin is sometimes mixed with wax, which will reduce the specific gravity of the latter. Wax has the specific gravity of 0.955 to 0.967; the specific gravity of paraffin varies from 0.870 to 0.877. Wax, when placed in alcohol (specific gravity, 0.961), will fall to the bottom; should it float, we may suspect it to be mixed with paraffin. The U. S. P. directs the following tests for wax: "If 1 Gm. of yellow wax be boiled, for $\frac{1}{2}$ an hour, with 35 Cc. of a 15 per cent aqueous solution of sodium hydrate, the volume being preserved by the occasional addition of water, the wax should separate, on cooling, without rendering the liquid opaque, and no precipitate should be produced in the filtered liquid by hydrochloric acid (absence of fats or fatty acids, Japan wax, resin); nor should the same reagent produce a precipitate in water which has been boiled with a portion of the wax (absence of soap). If 5 Gm. of yellow wax be heated in a flask, for 15 minutes, with 25 Cc. of sulphuric acid, to 160° C. (320° F.), and the mixture then diluted with water, no solid, wax-like body should separate (absence of paraffin). If a portion of yellow wax be ignited on platinum, it should not emit the odor of acrolein (absence of tallow and other fats)"—(U. S. P.).

Besides the methods here indicated an extremely useful method of analysis of beeswax has been introduced within the last 15 years, and consists in the determination of the *acid number*, and of the *ether number*, also certain other numbers. The *acid number* denotes the number of milligrams of potassium hydroxide required to saturate the free acids contained in 1 gram of wax. The *ether number* is the number of milligrams of potassium hydroxide necessary to saponify the ethers of 1 gram of wax. As these numbers vary only between narrow limits for pure wax, it is evident that any admixture of an adulterant like rosin, for example, which has a high acid number, may be easily recognized by titration with an alkali. For an interesting and instructive article on the subject of wax analysis, along the lines briefly indicated, see L. F. Kebler, *Amer. Jour. Pharm.*, 1893, p. 585; compare *ib.* p. 380. Also see paper by Prof. Bedford in *Proc. A. P. A.*, 1877, p. 444.

Action and Medical Uses.—Wax exerts little or no influence upon the system, though it has been recommended, combined with olive oil and the yolk of egg, in *diarrhœa*, *dysentery*, and *inflammation of the alimentary mucous membrane*. Its principal employment is in the preparation of ointments, cerates, and plasters, of which it forms an ingredient, imparting to them due consistence and tenacity.

Related Products.—**JAPAN WAX.** *Insect white wax of China.*—This wax is said to be obtained in Japan from the *Rhus succedaneum*, and other trees, being produced, as is supposed, by an insect, *Coccus sinensis*, Westwood, which feeds upon the tree. Huber states that the insect has the power of transmuting sugar into wax, which latter is, in fact, a secretion. It is said, however, that the Japanese make candles from the oil of the seeds of the *Rhus succedaneum*; and Nees von Essenbeck states that the wax from this tree greatly resembles the Japanese wax found in commerce. Japanese wax closely resembles white beeswax, but is less white and more yellowish, with a more tender and friable consistence, and a crystalline appearance. It occurs in circular cakes of from 4 to 4½ inches in diameter, nearly an inch thick, flat on one side, and rounded off on the other, as if cast in a small saucer, and is also met with in large square blocks or cases, weighing from 100 to 150 pounds. Its fusing point varies from 45° to 48.8° C. (113° to 120° F.), and, when melted, it will unite with beeswax, lard, etc., and more perfectly incorporates with cacao butter than either spermaceti or wax. It has a rancid-like taste and odor; is far more soluble in alcohol than beeswax, and, unlike this last, it is saponified by caustic alkalis. It is chiefly palmitin, with a small quantity of glycerides of arachidic and stearic acids. It is said to be adulterated sometimes with water, samples containing from 15 to 20, and even 30 per cent of this fluid. When thus adulterated the wax loses its transparent and shining appearance, becomes opaque, white, and very brittle. The water may be separated by simple fusion, or by fusion in water acidulated with sulphuric acid, when the presence of an alkali in the water of falsification is suspected.

CARNAUBA WAX.—A wax from the north of Brazil, *wax of Carnahuba*, a product of the palm, *Copernicus cerifera*, has been introduced into commerce, which possesses the advantage over beeswax of not melting so readily, as it requires a heat of 84° C. (183.2° F.). It readily saponifies, yielding an acid upon the decomposition of the soap by an acid; treated with alcohol, it gives cerotic acid, which melts at 77° C. (170.6° F.). As it is not affected by finger-marks at the temperature of the hand, it is much used as a furniture polish.

There are other forms of vegetable wax, but they do not enter prominently into our commerce. Among them are **OCOTILLA WAX** (from the bark of *Fouquieria splendens*); **ARBOL DE LA CERA** (from *Myrica jalapensis*), employed in Mexico in jaundice and diarrhoea. **OCUBA WAX** is from the fruit of a Para shrub; while a wax, used by the natives in making candles, is yielded by the *Ceroxylon andicolum*, a palm of the Andes.

CERATA.—CERATES.

Cerates are agents intended for external application, and are composed of wax, or spermaceti, combined with fatty matters, and with which resins, powders, etc., are frequently amalgamated. The articles entering into their composition should always be fresh, especially the fats, as these preparations are very prone to rancidity; the addition of benzoic acid tends to prevent this change, but its presence is not always desirable. Prof. E. S. Wayne found that by substituting paraffin for the wax, in cerates and ointments, the disposition to decompose was considerably retarded. Cerates are firmer in consistence than ointments, and are intended more as a sort of plaster than for inunction. The cerate is intermediate in consistence between the ointment and the plaster, about the consistence of cold butter, and may be spread with a spatula upon cloth or other substance, and be applied to the body, to which it will adhere without melting. In the preparation of cerates the water-bath will be found preferable to a direct exposure to the fire; and to effect the fusion of the materials, a very moderate heat will be sufficient. During the cooling of the compound it should be constantly and thoroughly stirred, not permitting one part to solidify before another. Cerates should be made in small quantity at a time, and should be kept in a cool place, in jars closely covered with tin foil, so as to exclude the air as much as possible. It was at one time thought that the use of wax in these preparations would be entirely superseded by paraffin, which does not become rancid, but experience has shown it to be objectionable on account of the granular character it gives to the cerate. Yellow wax is found to be less liable to become rancid than white wax.

CERATUM (U. S. P.)—CERATE.

SYNONYMS: *Simple cerate, Lard cerate, Ceratum simplex, Ceratum adipis.*

Preparation.—“White wax, three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; lard, seven hundred grammes (700 Gm.) [1 lb. av., 8 ozs., 303 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Melt them together and stir the mixture constantly until it is cool”—(U. S. P.).

This preparation should be perfectly bland, and great care should be observed in selecting lard entirely free from rancidity. To prevent any decomposition a low heat should be employed. This is not designed for inunction, though often improperly directed for that purpose. An old formula is as follows: Melt together prepared hog's lard 4 ounces, and white wax 2 ounces, agitating the whole briskly until cool. Put up in small vessels and cover well with tin foil, to protect as much as possible from the action of the atmosphere.

Action and Medical Uses.—Simple cerate forms a mild and cooling application to irritated surfaces, wounds, excoriations, burns, blisters, etc. Mr. W. J. M. Gordon, pharmacist of this city, formerly prepared a "paraffin cerate," which has been found a very useful article. It is composed of paraffin 2 drachms, oil of almonds $\frac{1}{2}$ ounce, white wax 1 drachm, oil of roses 2 drops. Simple cerate has been advised by G. W. Sloan (*A. P. A. Proceed.*, 1884) as an excipient for certain readily oxidizable pill-masses.

STRATINUM.—A class of substances resembling the cerates in consistence, was proposed by Dr. W. H. Mielcke, in 1881, under the name of *stratina* or *stearins*. Suet or tallow formed the base, which was compounded with other bodies, such as wax, dehydrated lead plaster deprived of its glycerin, nutmeg oil, and various medicaments.

CERATUM CALAMINÆ.—CALAMINE CERATE.

SYNONYMS: *Turner's cerate*, *Cerate of zinc carbonate*.

Preparation.—Take of prepared calamine 1 ounce; simple cerate 5 ounces; mix them well together (*Ed.*).

Or, take prepared carbonate of zinc, wax, of each, $\frac{1}{2}$ pound; olive oil, 16 fluid ounces (*Imp.*). Melt the wax in the oil, remove them from the fire, and as soon as the mixture begins to concrete, add the carbonate of zinc, and stir briskly until they are cold (*Lond.*).

Action and Medical Uses.—This cerate is an excellent desiccant and astringent application to burns, scalds, erysipelatous ulcerations, chafings, etc. (*P.*).

CERATUM CAMPHORÆ (U. S. P.)—CAMPHOR CERATE.

SYNONYM: *Unguentum camphoratum*.

Preparation.—“Camphor liniment, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; white wax, three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; lard, six hundred grammes (600 Gm.) [1 lb. av., 5 ozs., 72 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Melt the white wax and lard with the aid of a gentle heat; then add the camphor liniment, and stir the mixture occasionally until it has become cold”—(*U. S. P.*).

This preparation is somewhat softer than the cerates in general. It contains about 2 per cent of camphor. This preparation, formerly (*U. S. P.*, 1880), contained less than 1 per cent of camphor, and was originally intended and is now used as a basis for the extemporaneous preparation of Goulard's cerate.

Action and Medical Uses.—Antipruritic and slightly anodyne. It possesses no advantages over camphorated oil.

Other Camphor Cerates.—CAMPHOR CERATE, of a former edition of the *French Codex*, is prepared by melting together white wax (1 part), and lard (9 parts), employing moderate heat, and finally stirring into the mixture until dissolved, powdered camphor (3 parts), continuing the stirring until the whole is cold.

CERATUM CAMPHORÆ COMPOSITUM (*N. F.*), *Compound camphor cerate*, *Ceratum camphoratum*, *Camphor ice*.—*Formulary number*, 19: “Camphor, in coarse powder, one hundred and seven grammes (107 Gm.) [3 ozs. av., 338 grs.]; white wax, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; castor oil, two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.]; spermaceti, four hundred and eighty grammes (480 Gm.) [16 ozs. av., 408 grs.]; carbolic acid, liquefied by warming, two grammes (2 Gm.) [31 grs.]; oil of bitter almond, one gramme (1 Gm.) [15 grs.]; benzoic acid, ten grammes (10 Gm.) [154 grs.]. Melt the white wax and spermaceti on a water-bath, add the castor oil and afterwards the camphor, and continue heating and stirring until the camphor is dissolved. Then withdraw the heat, cover the vessel, and when the mixture has somewhat cooled, add the remaining ingredients, and thoroughly incorporate them by stirring. Lastly, pour the cerate into suitable molds”—(*Nat. Form.*).

For other cerates containing camphor, see *Ceratum Cetacei*.

CERATUM CANTHARIDIS (U. S. P.)—CANTHARIDES CERATE.

SYNONYMS: *Emplastrum cantharidis*, *Emplastrum vesicans*, *Emplastrum epispasticum*, *Emplastrum vesicatorium*, *Blistering cerate*, *Blistering plaster*.

Preparation.—“Cantharides, in No. 60 powder, three hundred and twenty grammes (320 Gm.) [11 ozs. av., 126 grs.]; yellow wax, one hundred and eighty grammes (180 Gm.) [6 ozs. av., 153 grs.]; resin, one hundred and eighty grammes (180 Gm.) [6 ozs. av., 153 grs.]; lard, two hundred and twenty grammes (220 Gm.) [7 ozs. av., 333 grs.]; oil of turpentine, one hundred and fifty cubic centimeters (150 Cc.) [5 fl $\bar{3}$, 36 m]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. “Moisten the cantharides with the oil of turpentine, and set the mixture aside, well covered, for 48 hours. Then add it to the yellow wax, resin, and lard, previously melted and strained through muslin, and keep the mixture in a liquid condition, by means of a water-bath, stirring occasionally, until its weight has been reduced to one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Then remove it from the bath, and stir it occasionally until it is cool”—(*U. S. P.*).

This preparation contains 32 per cent of cantharides, and will always vesicate, providing the flies used are of good quality. It should not be heated, in preparation, higher than 100° C. (212° F.), lest the catharinin be lost with the aqueous vapors given off from the powder employed, thus reducing the strength of the cerate. The vapors given off, when heating higher than the above-mentioned point, are liable to produce vesication of the hands and face of the operator. Turpentine, being a solvent of catharinin, is employed to render that body more readily soluble in the fats employed. In 1860, Wm. R. Warner proposed a formula, which differs principally in embodying an alcoholic extract of cantharides, in place of the powdered drug. This formula was adopted by the *U. S. P.*, of 1880, under the name of *CERATUM EXTRACTI CANTHARIDIS*, and is by many preferred to the present official cerate. This is practically reproduced in the formula of the *National Formulary* given below.

Action and Medical Uses.—As a blistering agent (see *Cantharis*).

“*CERATUM EXTRACTI CANTHARIDIS* (N. F.). (*U. S. P.*, 1880). *Cerate of extract of cantharides.*—*Formulary number*, 20: Cantharides, in No. 60 powder, three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; resin, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; yellow wax, three hundred and fifty grammes (350 Gm.) [12 ozs. av., 151 grs.]; lard, three hundred and fifty grammes (350 Gm.) [12 ozs. av., 151 grs.]; alcohol, a sufficient quantity.

“Moisten the cantharides, with one hundred and eighty cubic centimeters (180 Cc.) [6 fl $\bar{3}$, 41 m] of alcohol, and pack firmly in a cylindrical percolator; then gradually pour on alcohol, until one thousand eight hundred cubic centimeters (1800 Cc.) [60 fl $\bar{3}$, 415 m] of percolate are obtained, or until the cantharides are exhausted. Distill off the alcohol by means of a water-bath, transfer the residue to a tared capsule and evaporate it, on a water-bath, until it weighs one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grains]. Add to this the resin, wax, and lard, previously melted together, and keep the whole at a temperature of 100° C. (212° F.), for 15 minutes. Lastly, strain the mixture through muslin, and stir it constantly until cool” (*Nat. Form.*).

CAMPHORATED CANTHARIDAL PLASTER.—A camphorated cantharidal plaster is prepared by spreading a strong ethereal (or chloroformic) solution of camphor on a plaster of cantharides cerate. This, on evaporation, leaves a film of camphor on the surface of the cerate.

Vesicating cloth, or *blistering taffetas*, are occasionally prepared. The *Charta Epispastica* of the *U. S. P.* will probably fulfil all the indications for these various preparations.

CERATUM CETACEI (U. S. P.)—SPERMACETI CERATE.

SYNONYMS: *Emplastrum spermatis ceti*, *Ceratum labiale album*.

Preparation.—Spermaceti, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; white wax, three hundred and fifty grammes (350 Gm.) [12 ozs. av., 151 grs.]; olive oil, five hundred and fifty grammes (550 Gm.) [1 lb. av., 3 ozs., 175 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Melt together the spermaceti and white wax; then add the olive oil, previously heated, and stir the mixture constantly until it is cool”—(*U. S. P.*).

This preparation should be perfectly free from lumpiness, should not be rancid, and should have a white color. Should the olive oil be added without previous

heating, a lumpy cerate is produced. The following old formula also produces a spermaceti cerate:

"Take of olive oil, 6 parts; white wax, 3 parts; spermaceti, 1 part. Heat the oil gently; add the wax and spermaceti; stir the whole briskly when it is fluid, and continue the agitation until it is cool" (*Ed.*). It is found that this cerate may be preserved a much longer time when made of yellow instead of white wax, and of olive oil not bleached (J. B. Barnes).

Action and Medical Uses.—Spermaceti cerate is used as a mild and unirritating application to *superficial ulcers, excoriations, blisters*, etc.; more active ingredients are sometimes added to it (P.).

Other Cerates.—**RED LIP-SALVE.** Place in a vessel, oil of almonds, 1 pound; spermaceti, white wax, alkanet-root, of each, 2 ounces. Melt over a steam or water-bath, and allow the articles to digest on the alkanet 4 or 5 hours to extract its color; then strain through fine muslin, and add 2 drachms of oil of roses just before the mixture cools. Stir well together.

WHITE LIP-SALVE.—Melt, as above, oil of almonds, 4 ounces, with white wax and spermaceti, each, 1 ounce. When nearly cool, add oil of bitter almonds, $\frac{1}{2}$ drachm; oil of geranium, 15 minims. Stir thoroughly together. After the lip-salve is poured into pots, and has become cold, a red-hot iron must be held over it temporarily, in order that the heat radiated from the iron may melt the surface of the salve, and make it even and smooth (*Amer. Jour. Pharm.*, Vol. XXVIII, p. 86).

CAMPHOR COLD-CREAM is made by melting together almond oil, wax, spermaceti, of each, 1 pound; now pass into the mixture, in a very small stream, of rose water, 1 pound, agitating constantly until the whole is introduced and well incorporated. Then add powdered camphor, 2 ounces; oil of rosemary, 1 drachm.

ROSE COLD-CREAM is made similarly of almond oil, rose water, each, 1 pound; white wax, spermaceti, each, 1 ounce; oil of roses, $\frac{1}{2}$ drachm.

CAMPHOR BALL is made by melting together, spermaceti, 3 drachms; white wax, 4 drachms; almond oil, 1 ounce; and then adding powdered camphor, 3 drachms.

CAMPHOR ICE is made by melting spermaceti, 1 drachm, with almond oil, 1 ounce, and adding powdered camphor, 1 drachm (see also *Ceratum Camphoræ Compositum*, N. F.).

CERATUM ROSATUM. *Rose cerate, Lip-salve.*—White wax, 50 parts; oil of almonds (expressed), 100 parts; carmine, $\frac{1}{2}$ part; essential oil of rose, $\frac{1}{2}$ part. Rub the carmine with a portion of the oil. Melt the wax and almond oil together with moderate heating; add the carmine (in oil) when the mixture has partially cooled, stirring all intimately together, and lastly, add the oil of rose. This is in accordance with the *French Codex*.

CERATUM CROTONIS.—CROTON-OIL CERATE.

Preparation.—Melt lard, 5 ounces, with white wax, 1 ounce, and, when nearly cool, add croton oil, 2 ounces, and stir until cool.

Action and Medical Uses.—Croton-oil cerate is a rubefacient and vesicant, and may be used in all cases where such actions, or counter-irritation, are demanded.

CERATUM PLUMBI SUBACETATIS (U. S. P.)—CERATE OF LEAD SUBACETATE.

SYNONYMS: *Unguentum glycerini plumbi subacetatis, Goulard's cerate, Ointment of glycerin of lead subacetate.*

Preparation.—"Solution of lead subacetate, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; camphor cerate, eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.]; to make one thousand grammes (1000 Gm.) [2 lb. av., 3 ozs., 120 grs.]. Mix them thoroughly. This cerate should be freshly prepared, when wanted"—(*U. S. P.*).

Care should be taken, in making this cerate, that the camphor cerate be not rancid. Both the *German* and *British Pharmacopœias* employ no fats in the preparation of this cerate, hence their greater stability. Goulard's cerate rapidly assumes a yellow color, and shortly becomes so rancid as to render it unfit for medicinal purposes.

Action and Medical Uses.—Protective and astringent. Should be cautiously used on large raw surfaces, lest lead poisoning ensue from absorption. When rancid this cerate is irritating, and should be discarded, but when freshly prepared, it forms a good dressing for *blisters, excoriations, ulcers*, and to *suppurative parts*.

CERATUM RESINÆ (U. S. P.)—RESIN CERATE.

SYNONYMS: *Basilicon ointment, Unguentum resinæ, Ointment of resin.*

Preparation.—"Resin, three hundred and fifty grammes (350 Gm.) [12 ozs. av., 151 grs.]; yellow wax, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; lard, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Melt them together at a moderate heat, strain the mixture through muslin, and allow it to cool without stirring. In cold weather use the following proportions; Resin, three hundred and fifty grammes (350 Gm.) [12 ozs. av., 151 grs.]; yellow wax, one hundred and twenty grammes (120 Gm.) [4 ozs. av., 102 grs.]; lard, five hundred and thirty grammes (530 Gm.) [1 lb. av., 1 oz., 304 grs.]"—(U. S. P.).

An old formula reads: "Take of resin 5 ounces, axunge (lard) 8 ounces, bees-wax 2 ounces. Melt them together with a gentle heat, and then stir the mixture briskly while it cools and concretes" (Ed.). Strain it while it is hot.

Action and Medical Uses.—This cerate forms a mildly stimulant, digestive, and detergent application to ulcers which follow burns, scalds, etc., or which are of a foul or indolent character, and also to blistered surfaces to promote a discharge (P.).

CERATUM SABINÆ.—SAVINE CERATE.

SYNONYMS: *Ointment of savin, Unguentum sabinæ.*

Preparation.—Take of lard $7\frac{1}{2}$ ounces, resin $1\frac{1}{2}$ ounces, yellow wax 3 ounces, fluid extract of savin 2 ounces. Melt together the lard, resin, and wax, and when nearly cold, having stirred it constantly, add the fluid extract, and continue the stirring to completion.

Action and Medical Uses.—Savin cerate is applied to blistered surfaces, to maintain a constant discharge. It is less irritating than the cerate of cantharides, and has no tendency to excite strangury. When well prepared it has a fine green color, is uniform and transparent, without any tendency to separate, and has a smell like that of the plant.

Related Product.—CERATUM SABINÆ (N. F.) (U. S. P., 1890). *Savine cerate.*—Formulary number, 21: "Fluid extract of savine, twenty-five cubic centimeters (25 Cc.) [325 M]; resin cerate, ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]. Melt the resin cerate by means of a water-bath, add the fluid extract of savine, and continue the heat until the alcohol has evaporated; then remove the heat, and stir constantly until cool"—(Nat. Form.).

CEREI.—CEREBOLI.

SYNONYM: *Bougies.*

Preparation.—Bougies are made by dipping strips of soft linen cloth, bundles of thread, etc., rather wider at one end than at the other, into certain em-plastic or elastic compositions, folding them closely, and rolling them firmly on a smooth slab. Ready-made bougies are now a regular article of commerce. The following are some of the compositions held in most repute:

I. BELL'S.—Lead plaster 4 ounces, yellow wax, $1\frac{1}{2}$ ounces, olive oil 3 drachms.

II. HUNTER'S.—Olive oil 3 pounds, yellow wax 1 pound, red lead $1\frac{1}{2}$ pounds; boil together over a slow fire until combined.

III. SWEDIAUR'S WHITE.—White wax 1 pound, spermaceti 3 drachms, acetate of lead from 2 drachms to 1 ounce; boil together slowly.

IV. PIDERIT'S WAX.—Yellow wax 6 parts, olive oil 1 part.

V. GOULARD'S.—Yellow wax 6 ounces, melted and mixed by stirring with Goulard's extract of lead, from 2 drachms to 2 ounces.

VI. ELASTIC.—Boiled linseed oil 12 ounces, amber 4 ounces, oil of turpentine 4 ounces, in which is dissolved caoutchouc 5 drachms. Melt and mix the articles well together, and spread the compound at three successive intervals upon a silk cord or web. Place the pieces so coated, in a stove-oven heated to 65.5° C. (150° F.), and leave them in it for 12 hours, adding 15 or 16 fresh layers in

succession, until the instruments have acquired the proper size. Polish first with pumice stone, and finally smooth with tripoli and oil.

Surgical Uses.—Bougies are usually employed for dilating strictures, as of the urethra, vagina, neck of the uterus, and rectum. The largest size that can be conveniently introduced is first used, and the size gradually increased as the treatment progresses. The wax bougie is often employed for obtaining the form of a *urethral stricture*, its location and distance from the external orifice.

CEREVISIÆ FERMENTUM.—BEER YEAST.

The ferment obtained in the brewing of beer.

SYNONYMS: *Brewer's yeast*, *Barm*.

Preparation.—When an infusion of malt (barley steeped in water, left to incipient fermentation, and dried in a kiln), technically called *Wort*, is subjected to the process of fermentation, a dirty, grayish-brown substance gradually separates, forming in part a frothy scum (*top or upper yeast*), and partly a sediment (*bottom or lower yeast*); this is *yeast*, or *barm*.

Description and History.—Yeast is a thick, glutinous, foamy-like fluid of a wine-acid odor, and a rather unpleasant taste; it is a very complex mixture, containing water, alcohol, carbonic, acetic, and malic acids, potassium and calcium salts, saccharo-mucilaginous extract, and a cryptogamous growth consisting of nucleated cells, which was formerly named *Torula cerevisiæ*, of Turpin, but now known as *Saccharomyces cerevisiæ*. When exposed to moist air, or to a temperature above 15° C. (59° F.), yeast rapidly decomposes; but when subjected to a gentle heat, so as to dissipate its watery parts, it forms a fragile solid, which may be kept without change for a considerable time, but with a diminution of its fermentative properties.

Neither water nor alcohol dissolve yeast. Its most important property is, that when placed in contact with saccharine solutions at a temperature between 10° and 26.6° C. (50° and 80° F.), it excites vinous fermentation in them, converting their sugar into carbonic acid and alcohol. This was first pointed out by Thénard, in 1803, but the fungi producing this change were observed by Leeuwenhoek as early as 1680. Dr. Christison, by means of yeast, has been able to detect one part of sugar in 1000 parts of urine, of specific gravity 1.080. The cells appear as small, ovoidal, ellipsoidal, or somewhat pyriform, transparent, nucleated bodies, varying in size from $\frac{1}{1000}$ to about $\frac{1}{100}$ of an inch (P.).

The fermentative power of yeast is much impaired by drying it; a heat of 100° C. (212° F.) destroys yeast when moist, as does the addition of some of the concentrated acids, and of undiluted alcohol. It is also destroyed by boiling water, sulphurous acid, sulphate or acetate of copper, salt, nitrate of silver, black oxide of manganese, carbolic acid, creosote, quinine, strychnine, free alkalies, pyroligneous acid, salts of mercury, essential oils, etc. If, however, fermentation has commenced, the vegetable bases have no specific power of arresting the process. Arsenous acid, acetate of lead, and tartar emetic have no retarding effect upon the progress of fermentation. The keeping qualities and the taste of the products of fermentation depend largely on the nature of the yeast employed. The introduction of pure cultures of these micro-organisms by E. C. Hansen, of Copenhagen, has raised the arts involving fermentation to an almost exact science. For some interesting remarks on fermentation, by M. Pasteur, see *Amer. Jour. Pharm.*, Vol. XXX, p. 328; also see under *Alcohol*.

Yeast may be exposed to a very low temperature (−60° C. [−76° F.]) without losing its vitality, though the plant ceases to form and bud at a temperature of less than 5° C. (41° F.). On the other hand, it may be heated, if no water be present, to 100° C. (212° F.) without destroying its activity, but if water be present, its destruction is accomplished at 75° C. (167° F.). Commercial *dry yeast* is prepared by pressing out most of the water from yeast. *Vienna yeast* is the dried froth from the wort from barley malt, maize, and rye. *Patent yeast* is said to be flour dough mixed with yeast, or hop infusion, with malt added.

Action, Medical Uses, and Dosage.—Stimulant, tonic, nutritious, antiseptic, and laxative. Formerly used in *typhoid fevers* by mouth and injection,

and in *tyimpanitis* by enema. With or without the addition of olive oil, which renders it more laxative, it will be found highly beneficial in all *malignant ulcerations of the throat and mouth*, in diseases where there is a disposition to putridity, in *scarlatina*, and *low stages of fever*. Externally, in combination with elm bark and charcoal, it forms an excellent emollient and antiseptic poultice in *sloughing ulcers*, stimulating the vessels, removing the tendency to gangrene, and correcting the fetor. In the *furunculoid epidemic*, which existed in this country and Europe, given internally, in conjunction with quinine, yeast was found effectual in the treatment of *boils, carbuncles, and felons*. Yeast in doses of 1 fluid drachm, 3 or 4 times a day, taken immediately before meals, has been advised in *diabetes mellitus*. It has in some instances proved efficient, and is supposed to act by decomposing sugar or preventing its abnormal production in the stomach. The dose of yeast is from $\frac{1}{2}$ to 1 fluid ounce, every 2 or 3 hours.

CERII OXALAS (U. S. P.)—CERIUM OXALATE.

FORMULA: $\text{Ce}_2(\text{C}_2\text{O}_4)_3 + 9\text{H}_2\text{O}$. MOLECULAR WEIGHT: 704.78.

SYNONYMS: *Oxalas cericus, Cerium oxalicum, Oxalate of cerium, Cerous oxalate.*

Source and Preparation.—Cerium oxalate is prepared by a tedious method from the Swedish mineral *cerite*, which is composed chiefly of the silicates of cerium, lanthanum, and didymium. "For its production the powdered mineral is digested with hydrochloric acid. The solution is evaporated to a small bulk, treated with sulphide of hydrogen, diluted and filtered. Ammonia water is then added in slight excess, the precipitate collected, washed with water, dissolved by means of diluted hydrochloric acid, and precipitated by solution of oxalic acid. This produces crude oxalate of cerium, from which the impurities (lanthanum and didymium), are separated by calcining it, whereby sesquioxide of cerium is produced with the oxides of other metals. The powder is then digested with solution of sal ammoniac which dissolves all but the cerous oxide. This is then dissolved in diluted hydrochloric acid, and oxalic acid solution added until in slight excess. The precipitate of oxalate of cerium is then dried. It will be observed that the object of the foregoing roundabout process is to obtain *chloride of cerium*, and that from this the oxalate is in reality prepared by decomposition with oxalic acid" (Lloyd's *Chemistry of Medicines*).

Description and Tests.—"A white, granular powder, without odor or taste, and permanent in the air. Insoluble in water, alcohol, ether, or in solutions of potassium or sodium hydrate; soluble in diluted sulphuric or hydrochloric acid"—(U. S. P.). When heated in a current of hydrogen it decomposes, leaving the sesquioxide, or so-called *cerous oxide*. Cerium oxalate feels gritty when chewed, and seems to impart a sensation as if the teeth would adhere when moved upon each other.

"When heated to redness, it is decomposed, leaving a residue of reddish-yellow ceric oxide (a brown color would indicate the presence of didymium). On boiling the salt with potassium or sodium hydrate T.S., white cerous hydrate is left as insoluble residue, while in the filtrate, supersaturated with acetic acid, calcium chloride T.S. will produce a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. If the yellow residue left after heating be dissolved in concentrated sulphuric acid, and a small crystal of strychnine added, a deep-blue color will appear, which will rapidly change to purple and then to red. From the solution in diluted hydrochloric or sulphuric acid, potassium hydrate T.S. precipitates white, cerous hydrate, which does not redissolve in an excess of the reagent, and gradually turns yellow in contact with air. Ammonium carbonate T.S. precipitates white, cerous carbonate, which is somewhat soluble in an excess of the reagent. If 0.1 Gm. of cerium oxalate be dissolved in 1 Cc. of sulphuric acid, and 2 Cc. of potassium sulphate T.S. be added, small, colorless crystals of cerium potassium sulphate will be deposited after some time. No effervescence should occur when the salt is dissolved in diluted hydrochloric acid (absence of carbonate); nor should the solution be colored or rendered turbid on the addition of an equal volume of hydrogen sulphide T.S. (absence of arsenic, etc.). On boiling the salt with potassium or sodium hydrate T.S. and filtering,

no precipitate should be produced in the filtrate either by ammonium chloride T.S. (absence of aluminum), or by ammonium sulphide T.S. (absence of zinc)" —(U. S. P.).

Action, Medical Uses, and Dosage.—Cerium oxalate allays certain forms of vomiting, being best adapted to that reflex disturbance of uterine origin, and less valuable where the vomiting depends upon simple gastric irritation or destructive processes going on within the stomach. To a certain extent it will sometimes relieve the vomiting due to gastric irritability in *dyspepsia*, *phthisis*, and other chronic wasting diseases. Its reputation as a remedy for cough and chorea has not been well sustained. Its most decided effects are in the vomiting of pregnancy, and even here it often fails. Prof. Scudder alludes to its probable special influence upon the female reproductive apparatus, and states that he has given the remedy (2 x trit.) in ulcerated cervix uteri and uterine irritation with leucorrhœal discharges, with apparent success. It has been asserted a useful remedy for dysmenorrhœa in robust, fleshy women, with scanty menses, and spasmodic, colicky, or tenesmic pain before or at the beginning of the flow, relief following the free establishment of the discharge. Six grains are given every hour until relieved (Webster, *Dynam. Therap.*, from *Med. Record*).

The dose of cerium oxalate ranges from 1 to 10 grains (preferably in powder), from 1 to 3 grains being the ordinary dose—every 4 hours. The valerianate of cerium is also used in the same doses for vomiting of pregnancy.

Specific Indications and Uses.—Nausea and vomiting of pregnancy with nervousness; dysmenorrhœa of plethora, with colicky, tenesmic pain at the outset.

Cerium and Its Salts.—**CERIUM** (Ce). Atomic weight, 141.2. Klaproth discovered this metal in 1803, though he believed it to be an earth. Simultaneously Berzelius and Hisinger obtained the metal, all three extracting it from the Swedish mineral *cerite* above noticed. Later it was obtained by Mosander by heating cerium chloride and sodium together, and Hillebrand and Norton obtained it from the chloride by electrolysis. The mineral *allanite*, found in New York and Pennsylvania, as well as in Scandinavia, contains the same silicates that *cerite* holds. Among other minerals *orthite*, *gadolinite*, etc., of northern Europe contain it. Cerium resembles in color iron, and like it tarnishes in the presence of a moist atmosphere, yellow, blue, and green shades being produced. Though hard, when warm it is malleable, and may be drawn into wire. Beautiful scintillations are produced when the metal is struck with flint, and it burns even more brilliantly in the air than magnesium. Two oxides are known, the blue-green powder, cerium sesquioxide (*cerous oxide*) (Ce_2O_3), and the white or pale-yellow cerium dioxide (*ceric oxide*) (CeO_2). Corresponding to these oxides are the two lines of *cerous* and *ceric* compounds.

CERIUM NITRATES ($\text{Ce}[\text{NO}_3]_3 \cdot 6\text{H}_2\text{O}$). Cerium nitrate forms very deliquescent prisms or scales, colorless, and readily soluble in water or alcohol. It is prepared by double decomposition of barium nitrate and cerous sulphate. Simpson, the discoverer of the medicinal properties of the cerium compounds, employed it as a nerve tonic. Probably of little value.

CERIUM BROMIDUM.—A sweet, chocolate-colored mass, having a styptic action, readily soluble in alcohol, but when added to water leaving an insoluble cerous salt. It is prepared by dissolving cerous carbonate in hydrobromic acid, and evaporating (Bullock, *Amer. Jour. Pharm.*, 1871).

CERIUM CARBONATES ($\text{Ce}_2[\text{CO}_3]_3 \cdot 9\text{H}_2\text{O}$). Scales of a silver-like brilliancy, produced by the changing of the flocculent white precipitate thrown down when cerous sulphate is decomposed by ammonium carbonate. Not soluble in water.

CETACEUM (U. S. P.)—SPERMA CETI.

"A peculiar, concrete, fatty substance, obtained from *Physeter macrocephalus*, Linné.

Class: Mammalia. *Order:* Cetacea.

Source and Preparation.—Spermaceti is obtained from the cachalot, or sperm whale, the *Physeter macrocephalus* of naturalists, a species of the order Cetacea, and family *Physeteridae*. It is a gregarious animal, inhabiting the Pacific ocean, the Indian Archipelago, and the Chinese and Australian seas. It varies in size, being from 50 to 80 feet in length, with a huge, quadrangular head, from 20 to 30 feet or more in circumference, and which constitutes about a third of its whole length. Spermaceti is found in various parts of its body, in small proportions, dissolved in its blubber, but that which is met with in commerce is obtained from large cavities in the upper part of the head; these are divided into numerous cells,

which are filled with a milky, oleaginous solution of spermaceti. From a large whale 40 to 60 hundred weight, of this fluid may be collected. It is removed from the cavities and boiled to separate the oleaginous matter from the solid substance, and as it cools, the spermaceti crystallizes. The oil is then drained off as much as possible, and the remainder is removed from the spermaceti by powerful pressure. The crude spermaceti is subsequently purified by fusing and skimming it, then fusing it in weak lye of potassa, and finally by a third fusion at a gentle heat; after which it is solidified in tin molds.

Description, Chemical Composition, and Tests.—Spermaceti is a concrete, crystalline, foliaceous, pearly-white substance, without much taste or odor, easily indented or scraped by the nail, slightly greasy, pulverizable on the addition of a little alcohol, or almond oil, fusible and combustible. It is freely soluble in boiling alcohol, which deposits it on cooling; also in fused fats or resins. It is soluble in sulphuric acid, which decomposes it, but the other mineral acids do not influence it. It differs from ordinary fats in not yielding glycerin when saponified, but in furnishing in its stead a monobasic alcohol termed *ethal*, or *cetyl alcohol* ($C_{26}H_{54}O$). The *U. S. P.* describes spermaceti as in "white, somewhat translucent, slightly unctuous masses of a scaly-crystalline fracture and a pearly lustre; odorless, and having a bland, mild taste. It becomes yellowish and rancid by exposure to the air. Specific gravity, about 0.945 at 15° C. (59° F.). It melts near 50° C. (122° F.), and congeals near 45° C. (113° F.). Insoluble in water, and nearly so in cold alcohol; soluble in boiling alcohol; also in ether, chloroform, carbon disulphide, fixed and volatile oils; only slightly soluble in cold benzoin. An alcoholic solution of spermaceti is neutral to litmus paper. If 1 Gm. of spermaceti be boiled with 1 Gm. of anhydrous sodium carbonate, and 50 Cc. of alcohol, and the mixture cooled and filtered, the filtrate, upon being super-saturated with acetic acid, may become turbid, but should not afford a precipitate (absence of stearic acid)"—(*U. S. P.*). Exposed for a length of time to atmospheric influence, spermaceti becomes yellow and rancid, owing to a small portion of oil (*oil of spermaceti*) contained in it, but may be purified by boiling in alcohol, which deposits the pure spermaceti as it cools. By this method, or when it is deprived of oil by means of an alkali, it becomes a nearly pure proximate principle, intermediate between wax and the concrete oils, and presenting all the leading properties of the ordinary article, but less unctuous, rather harder, and fusible only at 49° C. (120.2° F.). It is then termed *cetin* (*cetyl palmitate*) ($C_{44}H_{90}O_2$), and is soluble in 40 parts of boiling alcohol of specific gravity 0.821. When boiled in a solution of caustic potash, cetin is partially saponified, forming a brittle soap composed chiefly of palmitate of potassium, oleate of potassium, and a crystalline principle called *ethal* ($C_{26}H_{54}O$) (*cetyl alcohol*, or *cetyl hydrate*), and which soap is not wholly soluble in water. When melted or dissolved in hot alcohol it crystallizes beautifully; when acted on by nitric acid, it yields first, pimelic acid, which is then oxidized into adipic acid, which is finally converted into succinic acid. Besides cetin, *stearic*, *lauro-stearic*, and *myristic acids*, as well as other and higher alcohols, besides *ethal*, are present in spermaceti.

Action, Medical Uses, and Dosage.—Demulcent and protective, combined with equal parts of loaf-sugar, once used among children in domestic practice in coughs, colds, and catarrhal affections, and in irritation of the intestinal mucous membranes. If to spermaceti be added half its weight of olive oil, and after mixing this, powdered gum Arabic be added, and, finally, some water be added by degrees, an emulsion may be formed, useful for children and infants. Hollandt states that spermaceti may be reduced to the most impalpable powder, by melting it over a gentle fire, and then stirring it in a previously-warmed mortar until cold.

Spermaceti forms a useful ingredient of several cerates and ointments. It enters into the formation of a crayon which is of much value to chemists, druggists, and others, inasmuch as it enables them to write upon clean glass. It is made by fusing in a cup 4 drachms of spermaceti (or stearin), 3 drachms of tallow, and 2 drachms of wax; after which 6 drachms of red lead, and 1 drachm of potassa are to be stirred into it, keeping the whole mass warm for $\frac{1}{2}$ hour, when it is poured into glass tubes the thickness of a lead-pencil.

Related Wax.—BLACK WAX. An animal product introduced into England from the Pacific Islands and India.

CETRARIA (U. S. P.)—CETRARIA.

The lichen, "*Cetraria islandica* (Linné) Acharius"—(U. S. P.). (*Lichen islandicus*, Linné).

Class: Lichenes.

COMMON NAMES: *Iceland moss, Iceland lichen.*

Botanical Source.—Iceland moss is a perennial, foliaceous plant, from 2 to 4 inches high; the thallus is erect, tufted, olive-brown, paler on one side, lacin-

Fig. 65.

Cetraria islandica

iated, channeled, and dentato-ciliate, the fertile lacinæ being very broad. The shields are brown, oppressed, and flat, with an elevated border (L).

History.—This lichen is a native of the mountainous section of Britain and the northern countries of Europe, particularly Iceland. It is found as far south as France, Italy, Switzerland, and Spain, growing in mountainous elevations. It is likewise found in the antarctic countries, British America, and in the United States from the eastern states to the mountains of Carolina and westward to the Rocky Mountains, from Colorado northward. In northern Europe it has long been used for food under the name *moss*, *mus*, or *mossa* (*Pharmacographia*). Though called Iceland moss, none is exported from that island. It is diversified in color, being brownish or grayish-white on some parts, and of a reddish hue in others; it is without odor, with a mucilaginous,

bitter, somewhat astringent taste, and when dry the lichen is crisp, cartilaginous, and coriaceous, and is convertible into grayish-white powder. It swells up in water, absorbing more than its own weight of that fluid, communicating a portion of its bitterness to it, as well as a little mucilage. When long chewed it is converted into a mucilaginous pulp, and when boiled in water the decoction becomes a firm jelly on cooling.

Description.—The following article is required by the Pharmacopœia: "From 5 to 10 Cm. (2 to 4 inches) long, foliaceous, irregularly branched into fringed and channelled lobes, brownish above, whitish beneath, and marked with small, depressed spots; brittle and inodorous; when softened in water, cartilaginous, and having a slight odor; its taste is mucilaginous and bitter. It should be freed from pine leaves, mosses, and other lichens, which are frequently found mixed with it"—(U. S. P.).

Chemical Composition.—Iceland moss consists of starchy lignin, a peculiar starch, gum, uncrystallizable sugar, a substance closely related to chlorophyll, wax, various salts, and a bitter principle called *cetrarin* or *cetraric acid* ($C_{18}H_{16}O_8$), which it is said, has been used in Italy for cinchona. Christison states that it may be obtained pure "by boiling the coarsely-powdered lichen in 4 times its weight of rectified alcohol, filtering the solution when tepid, acidulating it with diluted hydrochloric acid, diluting it with 3 times its volume of water, and purifying the crystals which slowly form, by squeezing them and washing them with a little ether." As thus obtained, *cetrarin* is in white, microscopic, acicular crystals, permanent, odorless, intensely bitter, insoluble in water, sparingly so in cold alcohol, more so in boiling alcohol, or ether, and readily soluble in alkaline solutions. When its alkaline solutions are treated with acids, the *cetrarin* is procured without being changed in its properties; concentrated hydrochloric acid converts it into a blue coloring matter. It is said to prove an efficient febrifuge in 2 or 3 grain doses, administered every 2 or 3 hours. Iceland moss also contains *lichenostearic acid* ($C_{18}H_{34}O_8$), *fumaric acid* (*lichenic acid* of Pfaff [1826]), oxalic and tartaric acids, and *thallochlor* (of Knop and Schnedermann), a chlorophyll unaffected by chlorhydric acid. The most important part of Iceland moss is its nutritive principle, to which the name of *lichenin* or *lichen-starch* has been given, and which exists to the extent of 70 per cent. It may be obtained by macerating the chopped

lichen for 24 hours in 18 parts of water, containing $\frac{1}{15}$ of its weight of carbonate of potassium—strain off the bitter solution without pressure, and remove the rest of it from the residuum by maceration with cold water and simple straining. Boil the residuum in 9 parts of water down to 6, strain the decoction, and squeeze what is left in the cloth, and then allow the strained liquor to cool. A firm jelly is formed, which cracks and throws out much of the water, and then dries into a hard, black, glassy-like substance. The black coloring matter may be removed by boiling again, straining, cooling, and drying; upon which the *lichenin* is obtained in thin, transparent, and tough plates of a yellowish color. Cold water renders it gelatinous, boiling water dissolves it, forming a jelly on cooling; alcohol and ether do not affect it. Iodine renders its watery solution blue, and it is converted into sugar by sulphuric acid, and into oxalic acid by nitric acid. According to Berg this body is made up of a substance for which he retains the name *lichenin*, and another constituent, which alone imparts the blue color to iodine. Out of 30 per cent obtained from the drug, 10 per cent was of this latter body, unnamed by him, but for which others have proposed the name *lichenoid* (*isolichenin*). This latter principle is freely soluble in cold water, but very sparingly soluble in boiling water. Lichenin has the same composition as that of starch and cellulose ($C_{12}H_{20}O_{11}$), and is believed to be a modification of the latter, and in some respects resembles amidin.

Preparations.—**ICELAND MOSS JELLY** (*Gelatina lichenis islandici*). Washed Iceland moss 3 parts, water 100 parts. Make a decoction, strain, add white sugar 3 parts, and evaporate the whole to 10 parts. Official in *Pharmacopœia Germanica*.

DRIED SACCHARATED ICELAND MOSS (*Gelatina lichenis islandici saccharata sicca*).—Iceland moss 10 parts. Deprive the lichen of its bitterness by heating to 100° C. (212° F.), in a small amount of water, express, and wash with cold water. Boil the residue in water an hour, strain and decant the decoction, mix with sugar 10 parts, evaporate, dry and pulverize. This gives a grayish-brown product. This is official in the *French Codex*.

To deprive Iceland moss of its bitterness, the *Pharmacopœia Germanica* directs, Iceland moss 15 parts, to be macerated in tepid water 90 parts, containing carbonate of potassium 1 part, for 3 hours. The product is subsequently thoroughly washed with cold water.

Action, Medical Uses, and Dosage.—Demulcent, tonic, and nutritious. Excessive doses may induce nausea and looseness of the bowels, while ordinary doses improve the appetite, digestion, and general nutrition. Constipation is not produced by it, and the circulation is unaffected. Its nutritive qualities are undoubtedly due to its starch. The bitterness of cetrarin may be detected in the nursing mother's milk. Used as a demulcent in *chronic catarrhs, chronic dysentery and diarrhœa*, and as a tonic in *dyspepsia, convalescence, and exhausting diseases*. Boiled with milk it forms an excellent nutritive and tonic in *phthisis and general debility*. It relieves the cough of *chronic bronchitis*. Its tonic virtues depend on its cetrarin, the bitter principle which, if removed, renders the lichen merely nutritious. Dose in powder, 30 to 60 grains; of cetrarin, $1\frac{1}{2}$ to 3 grains. The jelly and decoction are most generally employed.

CHAMÆLIRIUM (HELONIAS).—BLAZING STAR.

The rhizome of *Chamælirium luteum*, Gray (*Helonias dioica*, Pursh; *Helonias lutea*, Aiton).

Nat. Ord.—Liliacæ (Melanthacæ, Br.).

COMMON NAMES: Unicorn root, False unicorn root, Blazing star, Starwort.

ILLUSTRATION: (See *American Dispensatory*, eighth and succeeding editions).

We have adopted Gray as authority in the name of this plant, therefore the term *Helonias dioica* of former editions will be replaced to conform with the generally accepted classification. The common name is *Unicorn root*, derived from the fact that the rhizome resembles a horn. Afterward this term was applied to *Aletris farinosa*, which is thus the *False unicorn*. *Chamælirium* is also known under the names *Drooping starwort*, *Devil's bit*, and in former editions of this work, and in other books, as *False unicorn*.

Botanical Source.—The Chamælorium is an erect, slender herb, about 2 feet high, and without branches. The stem is smooth, round, striate, and terminates

Fig. 66.

Chamælorium luteum.

History.—This plant is indigenous to the United States, and is abundant in some of the western states, growing in woodlands, meadows, and moist situations, and flowering in June and July. It is also found in low grounds from Canada to Georgia and Louisiana.

The rhizome of this plant has long been confounded with, and sold for, that of *Aletris farinosa*, and to such an extent that druggists generally have concluded the two must bear a very close resemblance. This is a mistake, as there is scarcely any likeness between them. The impression as to their similarity of appearance was strengthened by the *American Dispensatory*, p. 419, eighth and succeeding editions, viz.: "There has been, and still exists, much difficulty among druggists and herb-gatherers, in determining the difference between the roots of *Aletris farinosa* and *Helonias dioica*, as they greatly resemble each other," etc. With the view of correcting previous mistakes, and setting right the history of the two plants, we have produced fac-simile drawings of both plants (Figs. 14 and 66), and by a simple reference to our engravings of *Aletris farinosa* and a comparison with that of *Chamælorium*, it will be obvious: (1) "That the shape of the leaves and general appearance of the plant are entirely different. (2) The rhizomæ are utterly unlike, and do not in the least resemble each other."

It is to be regretted that so much confusion has existed with regard to these rhizomæ, and the difficulty must be ascribed to the common names given them, and not to a resemblance. We have upon the market, the rhizomæ of *Unicorn* and *False unicorn*, of *Stargrass* and *Starwort*, *Helonias dioica*, and *Aletris farinosa* and the majority of dealers and therapists are by no means decided as to the identity of either of them. When ordered by their common names, the roots from one section of country will be the reverse of those from other sections; and when stargrass or unicorn root is sold to a druggist the dealer is uncertain as to whether it will not be returned as "different from that previously purchased." Strict conformity to botanical names will assist in overcoming this extended and serious evil.

Description.—The rhizomæ of chamælorium are from $\frac{1}{2}$ an inch to 2 inches in length, and, when dry, average from $\frac{1}{4}$ of an inch to $\frac{1}{2}$ an inch in diameter. They are mostly curved (horn shape), but some are nearly straight; usually pre-morse (as though bitten off), but sometimes they are pointed. Externally, they are dark-brown, transversely wrinkled, rough and uneven, showing the stem-scars

upon the upper side. Around the entire rhizome are fibrous rootlets, scattered above and thicker below. The fresh fibers are succulent, with the exception, however, of a hard, ligneous, thread-like center, which remains from one season to another long after the soft external portion has decayed. This gives rise to the appearance of pores or pin-holes upon the surface of the root, through many of which the woody fibers still pass, and extend, as fragments, from $\frac{1}{4}$ an inch to 2 inches beyond the surface, and internally, to the central part of the rhizome. When the fibers are entirely decayed, the small, pin-like holes remain and are often mistaken for worm-holes. Remains of radical leaves are occasionally found attached to the upper end of the rhizome, below which will often be observed a bunch of dried fibers, and along the upper side of the rhizome may be seen the bases of several annual stems or stem-scars. Internally, the rhizome is very hard, of a horn-like color and texture, about $\frac{1}{3}$ of the central portion being a little lighter, and partly composed of fibrous matter, from the surface of which the rootlets rise. The dried rhizomæ exhale a peculiar, characteristic, not unpleasant odor, more strongly developed when bruised, or rubbed between the fingers. The taste is very bitter, disagreeable and acrid. The virtues are extracted by alcohol, and, when fresh, by alcohol or boiling water.

Chemical Composition.—The rhizome contains a yellowish bitter principle, for which the name *chamælinin* has been proposed by Dr. F. V. Greene. It is a neutral body in the form of a powder, insoluble in the ordinary solvents, except alcohol and water, with both of which it gives frothy solutions after the manner of saponin. By treatment with diluted acids it is resolved into grape sugar and *chamæliretin*, a resinous body dissolving in ether and alcohol. Chamælinin is said to act as a heart poison.

Action, Medical Uses, and Dosage.—*Helonias* is tonic, diuretic, and vermifuge; in large doses, emetic, and, when fresh, sialagogue. In doses of 10 or 15 grains of the powdered root, repeated 3 or 4 times a day, it has been found very beneficial in *dyspepsia*, *loss of appetite*, and for the removal of *worms*. It is more especially applicable in *indigestion*, *dyspepsia*, and *mal-assimilation*, where the trouble is reflex from, or associated with wrongs of the female reproductive apparatus. Such digestive disturbances as depend upon uterine and ovarian irritation, or upon lack of uterine activity, in *chlorotic anemia*, are benefited by it, as well as the gastric complications of *albuminuria*. It is not, however, of much value in albuminuria itself. It is said to render the urine alkaline. It is reputed beneficial in *colic*, and is valuable in *atony of the generative organs*. I have found this plant to possess a decidedly beneficial influence in cases of sexual lassitude in both sexes, and of *nocturnal emissions*, the result of excesses, especially in those instances where there are symptoms of gastric derangement with impaired memory, mental apathy, or indifference, and an enfeebled condition of the general system, with weakness or dull pain in the renal, or lumbo-sacral region (King). In diseases of the reproductive organs of females, and especially of the uterus, it is one of our most valuable agents, acting as a uterine tonic, and gradually removing abnormal conditions, while at the same time it imparts tone and vigor to the reproductive organs. Hence, it is much used in *leucorrhœa*, *amenorrhœa*, *dysmenorrhœa*, and to remove the tendency to repeated and successive *miscarriages*. A particular phase removed by it is the irritability and despondency that often attends uterine troubles. In *painful menstruation* it has been found especially adapted to those cases in which there is pelvic fullness, a sensation as if the womb and rectum were distended with blood, and the aching, bearing-down organs feel as if they would fall out of the body. Its action here is very decided when the smaller doses are employed. It is considered useful by some for the relief of the *vomiting of pregnancy*. *Helonias* is a decided tonic to the urinary tract, and has exerted some benefit in *diabetes insipidus*. The plant is said to kill cattle feeding on it; and the decoction to kill insects, bugs, and lice. Dose of the powder, from 20 to 40 grains; of the decoction, from 2 to 4 fluid ounces; of a saturated tincture, from 10 to 30 minims; of the hydro-alcoholic extract, from 2 to 4 or 5 grains; specific *helonias*, 1 to 20 drops. The *Helonias bullata*, with purple flowers, and probably some of the other species, possess similar medicinal virtues.

Owing to the confusion that once existed (compare *Aletria* and *Chamælirium*) concerning the rhizomes furnishing *helonias* and *aletria*, the therapy of these

drugs have been heretofore similarly given. Aletris, however, is more adapted to digestive disorders, while helonias is chiefly a uterine tonic.

Specific Indications and Uses.—Mental irritability and despondency; sexual lassitude; atony of the female reproductive organs; gastric debility, with anorexia, nausea, indigestion, and mal-assimilation, particularly when due to reflexes of uterine origin; sticky, slimy leucorrhœa; atonic urinary tract; dysmenorrhœa, with pelvic fullness and heaviness, as if congested, with a bearing-down sensation, as if the parts were about to fall out.

CHARTÆ.—MEDICATED PAPERS.

This class is known as medicated papers, and was introduced into the *U. S. P.* in 1870, having previously been official in the *French Codex* and *British Pharmacopœia*. The processes of preparation are given under each particular paper, the modes of coating, etc., necessarily varying according to the material employed. They (excepting potassium nitrate paper) are like plasters, differing, however, in being spread upon non-absorbent, or sized paper.

CHARTA CANTHARIDIS (N. F.)—CANTHARIDES PAPER.

SYNONYMS: *Charta epispastica, Charta vesicatoria, Blistering paper, Cantharides paper* (*U. S. P.*, 1880.) *Formulary number, 22.*

Preparation.—The *Nat. Form.* directs: "White wax, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; spermaceti, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; olive oil, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; Canada turpentine, ten grammes (10 Gm.) [154 grs.]; cantharides, in No. 40 powder, ten grammes (10 Gm.) [154 grs.]; water, one hundred cubic centimeters (100 Cc.) [3 fl. 3, 183 M]. Mix all the substances in a tinned vessel, and boil gently for 2 hours, constantly stirring. Strain through a woolen strainer without expressing, and by means of a water-bath, keep the mixture in a shallow, flat-bottomed vessel with an extended surface. Coat strips of sized paper with the melted plaster, on one side only, by passing them successively over the surface of the liquid; when dry, cut the strips into rectangular pieces"—(*Nat. Form.*).

Action and Medical Uses.—Applicable as a blistering agent when vesication is to be accurately limited, but less efficient than cantharides cerate when full and pronounced vesication is required. The parts must be well washed with soap and water before applying the paper.

CHARTA POTASSII NITRATIS (U. S. P.)—POTASSIUM

NITRATE PAPER.

SYNONYMS: *Saltpetre paper.*

Preparation.—"Potassium nitrate, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; distilled water, eight hundred cubic centimeters (800 Cc.) [27 fl. 3, 25 M]. Dissolve the potassium nitrate in the distilled water. Immerse strips of white, unsized paper in the solution, and dry them. Keep the paper in well-closed vessels"—(*U. S. P.*).

In making this preparation, which is sometimes known as *asthma paper*, it is essential that a paper free from chlorine and its compounds, and a potassium nitrate uncontaminated with chlorides be employed. If the medicated paper is to be used in making moxas, these precautions are not so necessary. The potassium salt should be completely dissolved, so that aggregations of the salt may not form upon the paper, thus causing the paper to burn unevenly. *Medicated cigarettes* may be prepared from this paper by rolling it with such leaves as those of belladonna, stramonium, digitalis, hyoscyamus, sage, etc., or the paper may be formed into a quill, whose edges are held in contact with each other by means of a little gelatin, and the medicated substance to be inhaled introduced into the

hollow tube. *Mozas* may be prepared by rolling the nitrated paper into firm, cylindrical sticks about $\frac{1}{4}$ inch in thickness and cutting them into sections of the desired length.

Action and Medical Uses.—This paper is to be burned and the fumes inhaled for the relief of *nervous asthma*. It is thought by some that the heating converts the potassium nitrate into potassium nitrite.

CHARTA SINAPIS (U. S. P.)—MUSTARD PAPER.

Preparation.—"Black mustard, in No. 60 powder, one hundred grammes (100 Gm.) [3 ozs. av., 213 grs.]; India rubber, ten grammes (10 Gm.) [154 grs.]; benzin, carbon disulphide, each a sufficient quantity. Pack the black mustard in a conical percolator, and gradually pour benzin upon it until the percolate ceases to produce a permanent, greasy stain upon blotting paper. Remove the powder from the percolator, and dry it by exposure to the air. Having meanwhile dissolved the India rubber in a mixture of one hundred cubic centimeters (100 Cc.) each, of benzin and carbon disulphide, mix the purified mustard with a sufficient quantity of the solution to produce a semi-liquid magma, and apply this, by means of a suitable brush, to one side of a piece of rather stiff, well-sized paper, so as to cover it completely, and then allow the surface to dry. A surface of sixty square centimeters should contain about 4 Gm. of black mustard deprived of oil. Before it is applied to the skin, mustard paper should be dipped in warm water for about 15 seconds"—(U. S. P.).

That of the *British Pharmacopœia* is inferior to this paper, inasmuch as the oil is not extracted from the mustard, nor has the paper prepared with gutta-percha solution the flexibility of that made as above directed. While not as useful as mustard cataplasm, mustard paper is more convenient for travellers, and has the advantage of being always ready for use.

Action and Medical Uses.—In this paper the adhesion is perfect, and the preparation remains unalterable by time or atmospheric action. To use it requires only to wet it with water for 12 or 15 seconds, and then apply upon the skin, when it becomes a most active sinapism. M. Paul Rigollot is the inventor. This sinapism has been found more efficient than ammonia in the *bites or stings* of horse-flies, gnats, mosquitoes, bees, wasps, etc. As soon as the first sensation of the sinapism is felt, the pain and swelling rapidly disappears, and in from 1 to 24 hours the cure is complete. It may be used in all cases where a sinapism is indicated, except, perhaps, in a mustard foot-bath; it requires no loss of time in preparation, no water, no fire, no flour, no linen, is easily conveyed about, and acts promptly.

CHELIDONIUM (U. S. P.)—CHELIDONIUM.

"The entire plant, *Chelidonium majus*, Linné"—(U. S. P.).

Nat. Ord.—Papaveraceæ.

COMMON NAMES: *Celandine, Chelandine, Tetterwort, Great celandine.*

ILLUSTRATION: Köhler's *Medicinal Pflanzen*, Vol. I, Plate 21.

Botanical Source.—This plant is an evergreen perennial, with a stem from 1 to 2 feet in height, branched, swelled at the joints, leafy, round, and smooth. The leaves are smooth, spreading, and very deeply pinnatifid. The leaflets, in from 2 to 4 pairs, from $1\frac{1}{2}$ to $2\frac{1}{2}$ inches long, about $\frac{3}{4}$ as broad, terminal one largest, all ovate, and cuneately incised or lobed; the lateral ones sometimes dilated at their lower margin, near the base, almost as if auricled; color of all a deep, shining green. The flowers are bright yellow, umbellate, and are borne on long, often hairy stalks; umbels thin, axillary, and pedunculate; calyx tawny, often hairy; petals 4, entire, yellow, and very fugacious; stamens numerous; capsules long, torulose, 2-valved, and 1-celled; seeds black and shining, each with a whitish, deciduous crest (L.).

History.—Celandine is a pale-green, fleshy herb, indigenous to Europe, and naturalized in this country; it grows along fences, by roadsides, in waste places, etc., and flowers from May to October. When the plant is wounded, a bright-yellow,

offensive juice exudes, which has a persistent, nauseous, bitter taste, with a biting sensation in the mouth and fauces. The root is the most intensely bitter part of the plant, and is more commonly preferred. Drying diminishes its activity. It yields its virtues to alcohol or water. The plant should be collected while in bloom.

Fig. 67.

Chelidonium majus.

Description.—"Root several headed, branching, reddish-brown; stem about 50 Cm. (20 inches long), light-green, hairy; leaves about 15 Cm. (6 inches) long, thin, petiolate, the upper ones smaller and sessile, light-green, on the lower side glaucous, lyrate-pinnatifid; the pinnæ ovate-oblong, obtuse, coarsely crenate or incised, and the terminal one often 3-lobed; flowers in small, long-peduncled umbels, with 2 sepals and 4 yellow petals; capsule linear, 2-valved, and many-seeded. The fresh plant contains a saffron-colored milk-juice, and has an unpleasant odor and acid taste"—(U. S. P.).

Chemical Composition.—Analysis has detected in this plant a deep-yellow bitter, resinous substance, an orange-colored, nauseous, and bitter gum-resin, mucilage, albumen, free malic acid, silica, and various salts (Chevallier and Lasaigne). Probst (1838) obtained a peculiar acid termed *che'idonic acid*; and an alkaloidal principle, forming neutral red salts with acids, which are narcotic and poisonous, denominated *chelerythrine* (*pyrrhopine*) ($C_{15}H_{17}NO_4$), predicted by Probst (1840) to be identical with *sanguinarine*, which Schiel, of St. Louis (1855), proved to be the case. More recently, however, G. König (1891) assigns to sanguinarine the formula $C_{20}H_{21}NO_4$, and pronounces chelerythrine to be *methyl sanguinarine* ($C_{21}H_{23}NO_4$) (see *Amer. Jour. Pharm.*). It is a gray powder, and excites violent sneezing when snuffed into the nostrils. Another alkaloidal principle, bitter, insoluble in water, and forming crystallizable salts, is called *chelidonine* ($C_{18}H_{17}N_3O_5$); also a neutral, yellow, crystallizable bitter principle, is termed *chelidoxanthin*.

The alkaloids are held in combination with malic acid and *chelidonic acid* ($C_7H_4O_6$), a bibasic acid capable of dissolving iron and zinc. It occurs in silky, acicular crystals, has a very sour taste, decomposes the alkaline carbonates, dissolves in hot water, slightly in alcohol and cold water, and when boiled with an alkali, yields acetone and oxalic acid (Lieben and Haitinger). Zwenger (1860) announced another acid, *chelidominic acid*, believed by Walz to be succinic acid, and by Schmidt to correspond to ethylene-succinic acid. It is believed to be identical with the yellow acid produced by treating chelidonic acid with cold alkali in excess.

Chelerythrine may be obtained by forming a strong ethereal tincture of the celandine root; through this pass hydrochloric acid gas, and dry the precipitated chloride, which is insoluble in ether. Then dissolve it in hot water, filter, precipitate by ammonia, dry the precipitate, dissolve it in ether, decolorize by animal charcoal, again precipitate by hydrochloric acid gas, and decompose the chloride by ammonia, as before (see *Sanguinaria*). Three additional alkaloids, *protopine* and *alpha- and beta-homochelidonine*, have been isolated by Schmidt from the commercial alkaloids, chelidonine and chelerythrine. The alkaloid, *chelidonine*, was found by this author identical with *stylophorine*, an alkaloid obtainable from the root of *Stylophorum diphyllum*, an observation confirmed by Selle (*Amer. Jour. Pharm.*, 1890).

Action, Medical Uses, and Dosage.—Stimulant, acrid, alterative, diuretic, diaphoretic, purgative, and vulnerary. As a drastic hydragogue it is fully equal to gamboge. The juice, when applied to the skin, produces inflammation, and even vesication, and has long been known as a caustic for the removal of warts; also applied to indolent ulcers, fungous growths, etc., and is useful in removing specks and opacities of the cornea, and in curing ringworms. Celandine is superior to arnica as a vulnerary; an alcoholic tincture of the root (3 ounces to 1 pint), will be found

an unrivaled external application to prevent or subdue *traumatic inflammations*. Used internally in decoction or tincture, and externally in poultice or ointment, for *scrofula*, *cutaneous diseases*, and *piles*. Likewise useful in *hepatic affections*, and is supposed to exert a special influence on the spleen. It is a remedy influencing the parts supplied with nerve force from the branches of the solar plexus, and with blood from the hepatic artery, and to some extent by the splenic artery. Both acute and subacute forms of *inflammation of the liver*, when suppurative action has not set in, are benefited by chelidonium. *Migraine*, *bilious headaches*, *supraorbital neuralgia*, *bilious dyspepsia*, with headache, and other gastric and intestinal disturbances, due to faulty action of the liver, are well treated with it. It is a remedy for so-called "*liver coughs*." *Hemorrhoids*, *hepatic* and *splenic congestion*, and *gastro-intestinal disorders*, due to capillary engorgement of the viscera, are conditions for its exhibition. It is one of the best of remedies for *biliary catarrh*, the result of hepatic congestion, and for *jaundice*, due to obstruction of the bile ducts, the mucous membranes of which are swollen from the subacute inflammation present. Full, tensive, or throbbing pain in the right hypochondrium, and pain extending to beneath the right scapula, are the guides to its use in these hepatic disorders. Prof. Scudder, who conceived a very favorable opinion of this remedy, favored the use of small doses of chelidonium where the tongue was somewhat pallid and enlarged, the skin sallow, full, and occasionally tinged greenish-yellow, the mucous membranes enfeebled and full, right hypochondrium full, abdomen tumid, feces light in color, and urine of high specific gravity, and pale, but cloudy. As a rule there is no general abdominal pain. Edema of the extremities is sometimes an added indication. The remedy has acted favorably in *biliary calculi*, and in the small dose ($\frac{1}{16}$ to $\frac{1}{8}$ drop, every 2 or 3 hours) the extravagant claim of having radically cured *hydrocele*, has been made by some leading Homœopaths. Dose of the powdered root, from $\frac{1}{2}$ to 1 drachm; of the fresh juice, from 30 to 40 drops, in some bland liquid; of the tincture, from 1 to 2 fluid drachms; of the aqueous extract, from 5 to 10 grains. The foregoing doses represent its gross action, but for the specific purposes for which it is now employed, the dose should be small, preferably from 1 to 15 drops of specific chelidonium. Prof. Scudder preferred it as follows: Specific chelidonium, gtt. x; aqua, fl̄iv. Mix. A tablespoonful every 3 or 4 hours.

Specific Indications and Uses.—"Full, pale, sallow tongue and mucous membranes; skin pale and sallow, sometimes greenish;" hepatic congestion; jaundice, due to swollen bile ducts; sluggish hepatic action; cough, with hepatic pain; fullness, with tensive or throbbing pain in the right hypochondrium, and pain extending to right shoulder; melancholia, headaches, and gastric disorders, dependent upon faulty action of the liver.

Related Species.—*Glaucium luteum*, Scopoli (*Chelidonium Glaucium*, Linné). Europe. Naturalized in the United States. *Horn poppy*. Grows near the coast and has yellow flowers. Resembles celandine somewhat, though possessing less acridity, has a saffron-yellow juice, and contains *sanguinarine*, *glaucine* (in the herb), and *glauco-picrine* (in the root), all white alkaloids. Narcotic and poisonous, occasioning delirium and visual disturbances, objects appearing yellow. The juice, mixed with egg albumen, has been used domestically in Provence for *piles* and *spasmodic anal stricture*, and the juice applied for *stings*, *contusions*, *ulcers*, etc.

Glaucium corniculatum, Curtius.—Similar to above plant, but has red flowers marked with a black spot at the base of the petals.

CHELONE.—BALMONY.

The herb, and especially the leaves of *Chelone glabra*, Linné.

Nat. Ord.—Scrophulariaceæ.

COMMON NAMES: *Balmoney*, *Snakehead*, *Turtlehead*, *Turtlebloom*, *Shellflower*, *Salt-rheum weed*.

Botanical Source.—This is a perennial, smooth, herbaceous plant, with a simple, erect, somewhat 4-sided stem, about 2 or 3 feet high. The leaves are opposite, sessile, or nearly so, smooth, oblong-lanceolate, acuminate, serrate, and of a dark, shining green above. The flowers are large, inodorous, white, rose color, or purple, subsessile, in a short, terminal, dense spike, somewhat resembling the head of a snake or tortoise; the corolla is inflated, bilabiate, and contracted at the

mouth; the upper lip is broad and arched, and keeled in the middle; the lower one woolly within; the calyx is deeply 5-parted, with 3 bracts at the base. Stamens 4, with hairy filaments and hairy, cordate anthers, a fifth sterile filament smaller than the others; ovary ovate; style long, exsert, and bending downward. The fruit is an oval, 2-celled, 2-valved capsule, with many small, wing-margined seeds (W.—G.).

Fig. 68

Chelone glabra

History.—This valuable medicinal plant is found in the United States in damp soils, flowering in August and September. The flowers are very ornamental, and vary in color, according to the variety of the plant, there being many varieties. The leaves are exceedingly bitter, but inodorous, and communicate their properties to both water and alcohol.

Chemical Composition.—W. Pfeuffer (1892), who made an approximate analysis of the over-ground portion of this herb, detected in the alcoholic and ethereal extracts, a glucosid, which, when decomposed, evolved a peculiar, disagreeable odor. The usual plant constituents were found, and from the ethereal extract crystals giving the reactions for gallic acid were obtained (A. P. A. Proc., 1892).

Action, Medical Uses, and Dosage.—Tonic, cathartic, and anthelmintic. Especially valuable in *jaundice* and *hepatic diseases*, likewise for the removal of *worms*, for which it may be used in powder or decoction, internally and also in injection. Used as a tonic in small doses, in *dyspepsia*, *debility of the digestive organs*, particularly when associated with hepatic inactivity, and during convalescence from *febrile* and *inflammatory diseases*. It is valuable after *malarial fevers* as a tonic and to unlock the secretions when checked by quinine. Recommended in form of ointment as an application to painful and inflamed *tumors*, irritable and painful *ulcers*, *inflamed breasts*, *piles*, etc. Dose of the powder, 1 drachm; of the tincture, 1 or 2 fluid drachms; of the decoction, 1 or 2 fluid ounces; specific chelone, 10 to 30 drops.

Specific Indications and Uses.—Gastro-intestinal debility, with hepatic torpor or jaundice; worms.

CHENOPODIUM (U. S. P.)—CHENOPODIUM.

"The fruit of *Chenopodium ambrosioides*, Linné, and variety *anthelminticum*, Gray"—(U. S. P.).

Nat. Ord.—Chenopodiaceæ

COMMON NAMES: *American wormseed*, *Wormseed*.

Botanical Source.—This plant, sometimes known also by the name of *Jerusalem oak*, has a perennial and branched root, with an erect, herbaceous, much-branched, furrowed stem, rising from 1 to 3 feet in height. The leaves are alternate or scattered, oblong-lanceolate, toothed, sinuate, nearly sessile, distinctly veined, attenuated at both ends, of a yellowish-green color, and marked beneath with small resinous atoms. The flowers are very numerous, small, of the same color as the leaves, arranged in long, slender, axillary, or terminal, *leafless* racemes; calyx with 5 ovate, concave, permanent segments; stamens 5, opposite to the segments of the calyx, and about as long, with awl-shaped filaments; styles 2 or 3, short; ovary orbicular, depressed; seeds solitary, lenticular, crustaceous, and covered by the permanent, 5-angled calyx (L.).

History and Chemical Composition.—Chenopodium is found growing in waste places in almost all parts of the United States, flowering from July to September, and ripening its seeds throughout the autumn, at which time they should be collected. The whole plant has a strong, unpleasant odor, which is owing to its essential oil (see *Oleum Chenopodii*). When first obtained, it is of a light straw

color, but gradually acquires a darker hue. The seeds contain a large quantity of this oil, which is obtained from them by distillation. The whole plant is occasionally employed, but the seeds only are official. *Chenopodin* has been obtained from the fresh plant, in the form of a white, tasteless, inodorous powder, soluble in 11 parts of water, 202 parts of cold alcohol, and soluble in diluted acids.

Description.—“Nearly 2 Mm. ($\frac{1}{16}$ inch) in diameter, depressed-globular, glandular, dull-greenish or brownish, the integuments friable, and containing a lenticular, obtusely-edged, glossy, black seed. It has a peculiar, somewhat terebinthinate odor, and a bitterish, pungent taste”—(*U. S. P.*).

Action, Medical Uses, and Dosage.—Anthelmintic and antispasmodic. It is used in various forms, as the expressed juice, electuary, or decoction, to expel the *lumbrici* in children. The dose of the juice is a tablespoonful, repeated night and morning; of the infusion, prepared by infusing 1 ounce of the recent plant in 1 pint of milk, with the addition of some aromatic, a wineglassful; of the electuary, made by thoroughly mixing the pulverized seed in honey or syrup, 20 or 40 grains. But the essential oil, on which the vermifuge properties depend is the best form, and is more generally employed. Its dose is from 4 to 8 drops mixed with sugar, or in emulsion, to be given morning and evening, for 4 or 5 days successively, and then, as with the other forms of administration, it should always be followed by a purgative. It is used in various combinations. Take of oil of wormseed and tansy, of each 1 ounce, spirits of turpentine $1\frac{1}{2}$ ounces, castor oil 1 pound. Mix. Dose, for a child, a teaspoonful every hour, until it operates; for an adult, a tablespoonful. Equal parts of chenopodium and jalap in decoction may be given in tablespoonful doses, on an empty stomach, 4 or 5 times a day. The oil has likewise been reputed beneficial in *amenorrhæa*.

Specific Indication and Use.—To expel lumbricoid worms.

Related Species.—The *Chenopodium ambrosioides*, Linné, which has been successfully used in chorea, and the *Chenopodium botrys*, Linné, which has been used with advantage in catarrh and humoral asthma, as an expectorant, are both indigenous, and though less powerful, possess somewhat similar properties; and, indeed, from the superior powers of the *C. anthelminticum*, it might possibly be found of more benefit in these affections than the above. The first species is official in many of the European countries where it is known as *Herba botrys mexicana* or *Mexican tea*. It is plentiful in our middle states. Its flower-spikes are dense and leafy. The second species is strongly aromatic, the odor resembling turpentine, and is known as *Oak of Jerusalem* and *Feather geranium*. It is naturalized in this country, being a native of Europe and Asia.

Chenopodium album, Linné, is *Common pigweed* or *Lamb's-quarter*. It is a mealy, smooth plant, having a saline, mucilaginous taste.

Chenopodium Bonus-Henricus, Linné. A somewhat mealy plant, having a saline, mucilaginous taste; a native of Europe, but naturalized in America and known in Europe as *Good King Henry*. It is a domestic application for pain, and is reputed antispasmodic and expectorant.

Chenopodium vulvaria, Linné. A mealy plant of Central Europe, having the smell of fish brine on account of the trimethylamine it contains. It is known as *Fetid goosefoot*, and employed in Europe, both locally and internally, in many nervous disorders.

Chenopodium quinoa.—Cultivated in Chili and Peru for its seeds, which yield a flour resembling oatmeal. The seeds contain 11 per cent of albumen and other protein matter, 5 per cent of sugar, 7.5 per cent of casein, and 40 per cent of starch. A bitter principle has been isolated from the variety known as *red quinoa*, and this variety has been employed as an antiperiodic and emetic.

CHIMAPHILA (U. S. P.)—CHIMAPHILA.

“The leaves of *Chimaphila umbellata* (Linné), Nuttall”—(*U. S. P.*); (*Chimaphila corymbosa*, Pursh; *Pyrola umbellata*, Linné). The whole plant may be employed.

Nat. Ord.—Ericaceæ.

COMMON NAMES: *Pipsissewa*, *Prince's pine*, *Ground holly*, *Wintergreen*.

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 165; Bigelow *Med. Bot.*, Vol. II, 21.

Botanical Source.—This plant is a small evergreen, nearly herbaceous, perennial herb, with a creeping, yellowish rhizome, from which are sent several simple, erect, or semi-procumbent stems, somewhat angular, marked with the scars of former leaves, and woody at their base; they grow from 4 to 8 inches in height. The leaves are in two or more irregular whorls, from 2 to 3 inches long, about one-fourth as wide, cuneate-lanceolate, acute at the base, sharply serrate, on short

petioles, coriaceous, shining, of a uniform dark-green color, paler below, and not spotted. The flowers are corymbose, nodding, of a light-purple color. The pedicels, with linear-subulate bracts about their middle, 8 lines long. The calyx is

Chimaphila umbellata.

small, consisting of 5 roundish, acute teeth, or segments, and much shorter than the corolla. The corolla is composed of 5 roundish, concave, spreading, cream-colored petals, exhaling a fragrant odor, and tinged at the base with purple. Stamens 10, hypogynous; filaments sigmoid, the lower half fleshy, triangular, dilated, slightly pubescent at the edges; the upper half filiform. Anthers 2-celled, each cell opening by a short, round, tubular orifice, which points downward in the bud, but upward in the flower. Pollen white; ovary globular, depressed, furrowed, obscurely 5-lobed, with a funnel-shaped cavity at the top, and supporting a large peltate, convex, obscurely 5-rayed stigma. Style short, straight, half as long as the ovary, inversely conical, inserted in the cavity of the ovary, and concealed by the stigma. The capsule is erect, depressed, 5-celled, 5-valved, with partitions from the middle of the valves. The seeds are numerous, linear, and chaffy (L.—W.—G.).

History.—This little herb is indigenous to the north temperate regions of both hemispheres, and is met with in the United States in dry, shady woods, flowering from May to August. The leaves have no odor when dried, but when fresh and rubbed they are rather fragrant; their taste is astringent, sweetish, and not disagreeably bitter. The whole herb is used. Boiling water or alcohol extracts the active properties.

Description and Chemical Composition.—"About 5 Cm. (2 inches) long, oblanceolate, sharply serrate above, wedge-shaped and nearly entire towards the base; coriaceous, smooth, and dark-green on the upper surface. It is nearly inodorous, and has an astringent and bitterish taste"—(U. S. P.). Mr. S. Fairbank found the leaves to contain gum, tannic acid, starch, pectic acid, extractive, resin, fatty matter, chlorophyll, yellow coloring matter, lignin, and golden-yellow, needle-shaped crystals, which he named *chimaphilin*. This yellow body is without taste or odor, freely soluble in alcohol, chloroform, ether, benzol, benzin, glacial acetic acid, and acetone, and in oils, both essential and fixed, but dissolves sparingly in water. It has a neutral reaction, and is volatile with aqueous vapors. *Arbutin* ($C_{12}H_{20}O_4 \cdot H_2O$), a crystalline, glucosidal principle, found also in other ericaceous plants, forming neutral, silky, colorless, bitter needles, and readily soluble in boiling water and alcohol, but sparingly so in ether, was found in this plant by Zwenger and Himmelmann, in 1864. Salts of potassium, calcium, iron, magnesium, chloride of sodium, phosphoric, sulphuric, and silicic acids were also found (*Jour. Trans. Md. Col. Pharm.*, March, 1860). Mr. E. S. Beshore (1887) also obtained chimaphilin, and found another crystalline body, of the composition $C_{20}H_{32}O$, melting at $236^\circ C.$ ($457.2^\circ F.$), by abstracting the dried drug with petroleum ether.

Mr. J. C. Peacock (*Amer. Jour. Pharm.*, 1892) failed to obtain chimaphilin from the fresh plant of *Chimaphila maculata*, but obtained it in the ordinary way from the dried plant, by distilling the drug with water. The influence of drying upon the yield of chimaphilin from *C. maculata* was likewise observed by him when attempting to abstract this substance by means of petroleum ether. Mr. Peacock found the fusing point of chimaphilin at 113 to $114^\circ C.$ (235.4° to $237.2^\circ F.$), and the composition of this substance to correspond with the formula $C_{20}H_{32}O$. Three other principles of a crystalline character were obtained from chimaphila, occurring respectively as "matted crystals," "tufted crystals," and "glistening crystals," all differing in solubility and other respects from any previously known constituents of the order Ericaceae (*A. P. A. Proc.*, 1892). In 1895, Mr. Ridenour confirmed Mr. Peacock's formula by the analysis of chimaphilin and some new derivatives

prepared by him; he succeeded, nowever, in obtaining chimaphilin from the fresh plant of *C. maculata*.

Action, Medical Uses, and Dosage.—Diuretic, tonic, alterative, and astringent. The fresh leaves, when bruised and applied to the skin, act as vesicants and rubefacients. Its alterative properties are marked, the processes of waste and nutrition being powerfully influenced by it. It is especially useful in *scrofula* and *chronic rheumatic* and *nephritic affections*. Irritation of any part of the urinary tract is relieved by it, and the circulation and nutrition of the part improved. The cases of all diseases in which it is of most value are those of debility, and particularly when a scrofulous taint is present. Its particular field is in *genito-urinary fluxes*, due to debility or depending upon a scrofulous diathesis. The more pronounced the catarrhal character of the disorder, the more valuable is the drug. *Catarrh of the bladder*, with offensive urine, or urine loaded with mucus, muco-pus, or even blood, are cases for its exhibition. Chronic affections of the kidneys, with muco-purulent discharges, are also conditions indicating it. The infusion is the best preparation. Do not make a decoction, as boiling impairs its virtues. It is also a remedy for *chronic prostatic irritation* and *chronic prostatitis*. Used both locally and internally, it is a good remedy for *scrofulous ulcerations*. The infusion has cured *ascites*, and has been advantageous in *strangury*, *chronic gonorrhoea*, and other *mucous profluvia*; and as an antilithic it is said to diminish lithic acid in the urine. In *dropsy* it can not be depended upon without the use of other more active measures, and is better adapted to cases accompanied with weakness and loss of appetite. In urinary disorders, it may be used as a substitute for uva ursi and buchu, to which it is preferable on account of being less obnoxious to the stomach. In many cutaneous diseases it has proved very efficient. Dose of the infusion, from 1 to 4 fluid ounces, 3 times a day; of the extract, from 10 to 20 grains, 3 or 4 times a day; a syrup may be prepared by macerating 4 ounces of the finely-bruised leaves in 8 fluid ounces of water for 36 hours, then subject the whole to percolation till a pint of fluid is obtained, evaporate to $\frac{1}{2}$ pint, and add 12 ounces of sugar. Dose, 1 or 2 tablespoonfuls; fluid extract, 3ss to 3j, largely diluted; specific chimaphila, 5 drops to 1 drachm, every 3 or 4 hours.

Specific Indications and Uses.—Atonic and debilitated states of the urinary organs, giving rise to lingering disorders, with scanty urine, but excessive voidings of mucus, muco-pus, or bloody muco-pus, offensive or non-offensive in character; smarting or burning pain with dysuria; chronic irritation of the urethra and prostate; chronic relaxation of the bladder walls; chronic prostatitis, with vesical catarrh.

Related Species and Drugs.—*Chimaphila maculata*, Pursh, *Spotted wintergreen*, may be known from the above by its leaves, which are opposite, or in threes, lanceolate, acuminate, rounded at the base, where they are broader than near the summit, remotely serrate, of a deep olive-green color, and veined with greenish-white. The *C. umbellata* leaves are broader near the summit, tapering toward the base, of a uniform shining-green color, serrated, and not marked with the whitish line along the mid-vein and veinlets. The *C. maculata* is probably possessed of similar powers with the official article, and may be used as a substitute. An extract of it is reputed to have cured *epilepsy*.

Pyrola rotundifolia, Linné; *Pyrola chlorantha*, Swartz; *Pyrola elliptica*, Nuttall; *Pyrola secunda*, Linné (see *Pyrola*).

Orthosiphon stamineus. *Java tea*.—This drug comes in the form of little oval, green leaves, finely toothed, and rolled like ordinary tea. Essential oil and a glucosid, *orthosiphonin* in crystals, are among its constituents. It is reputed powerfully diuretic, and, in doses of from 15 to 20 grains per day, it has been lauded in *uric acid diathesis*, *gravel*, *ascites*, and *nephritic colic*.

CHINOIDINUM.—CHINOIDINE.

SYNONYMS: *Chinoidinum*, *Chinoidina*, *Quinoidine*, *Quinoidina*, *Chinoidin*, *Quinoidin*, *Amorphous quinine*, *Precipitated extract of bark*.

History and Chemical Composition.—*Chinoidine* is a non-crystallizable alkaloid occurring in the mother liquors resulting from the manufacture of cinchona alkaloids. The name *chinoidine* (quinoidine), was first given by Sertürner to what he believed to be a new alkaloid, from cinchona barks, which, however, turned out to be a mixture of quinoidine and cinchonine, intermixed with a yellowish body that prevented crystallization. Liebig, after depriving quinoidine of its

crystallizable admixtures, thought it to be amorphous quinine, rendered non-crystallizable through the application of heat.

The chief constituents of commercial chinoidine of the present time are *diconchinine* ($C_{20}H_{24}N_2O_3$), when obtained from barks containing quinine and quinoidine in abundance, or *dicinchonine* ($C_{20}H_{24}N_2O_3$), when barks predominating in cinchonine or cinchonidine are manipulated. These two bodies are amorphous and not easily separable.

Description and Tests.—Commercial chinoidine usually appears in rolls or masses, of a brownish-black or almost black color, and when cold breaks with a resin-like, shining fracture. It is odorless, feebly bitter, and blues litmus paper. When warmed it becomes plastic and in the heat of summer it gradually takes the shape of the container. Water scarcely dissolves it; ether and benzene partially, and alcohol, chloroform, and diluted acids freely dissolve it. These solutions are extremely bitter, and exhibit right-hand polarization. After triturating chinoidine with boiling water and filtering the fluid which should then be transparent and colorless, it should remain so upon the addition of an alkali, thus showing the absence of alkaloidal salts. Not more than 0.7 per cent of ash should be left upon incineration.

Action, Medical Uses, and Dosage.—Chinoidine was introduced as a remedy for malarial manifestations, and is considered by many superior in some respects to quinine. It is slower to act, and the dose required is from $\frac{1}{2}$ to 2 times greater than that of quinine sulphate. It is claimed for it that it is equal in efficiency to the latter in simple malarial intermittents, and may be given before and during the chill without unpleasant results, and it never causes aural tinnitus. In chronic malarial disorders it is asserted that its power is greater than that of quinine, and persons toxically impressed with the latter may take chinoidine without unpleasant consequences, and with therapeutical benefit. Lastly, in malarial rheumatism, masked malaria, and as a tonic, it is regarded by some as far more effective than the quinine salts. It is undoubtedly valuable in malarial cachexia, and has the advantage of having but slight taste. If desired it may be given in sweetened, strong coffee. Dose for adults, 7 to 15 grains; for young children, 2 or 3 grains.

Related Preparations.—**TINCTURA CHINOIDINI.**—Tincture of chinoidine of the German Pharmacopœia, is prepared by dissolving the ingredients in the following proportions: Chinoidine (2 parts), in hydrochloric acid (1 part), and alcohol, sp. gr. 0.894 (17 parts). It is transparent in thin portions, dark brown in bulk, and excessively bitter. An equal measure of water and ammonia water precipitates the chinoidine from the tincture, causing the liquid to assume a yellowish color.

CHINOIDINI HYDROCHLORAS.—Chinoidine hydrochloride is a hygroscopic yellow or brownish-yellow powder produced by saturating with chinoidine warmed diluted hydrochloric acid, filtering, and condensing by evaporation.

CHINOIDINI CITRAS.—Chinoidine citrate. Transparent, soluble, reddish-brown scales, produced by dissolving chinoidine in a solution of citric acid in water, and evaporating to dryness.

CHINOIDINI TANNAS.—Chinoidine tannate. This is a yellowish-brown powder produced by mixing tincture of chinoidine (see above), diluted with water, and an aqueous solution of tannin, and lastly adding solution of acetate of ammonium. After several hours the precipitate is washed and dried at a heat not higher than 30°C . (86°F). Its solution in water and hydrochloric acid is deep-yellow in color.

CHINOIDINI BORAS.—Chinoidine borate. Take chinoidine 10 parts, boric acid 5 parts, and water 100 parts. Heat to the boiling point, and filter through moistened cotton. Again heat the clear fluid to the boiling point, filter out the resinous portion, and continue this filtration and boiling until resinous matter no longer separates. Evaporate to 10 parts, set aside a half day, at a temperature not above 15°C . (59°F). Now filter it from the acid and evaporate, when either transparent, brownish-yellow scales, or a yellowish powder will form. This has an alkaline reaction, is somewhat hygroscopic, is bitter to taste, and with water (3 parts), it produces a deep-yellow, clear solution, but with a greater amount of water (10 parts), the solution becomes turbid on boiling, and clear again upon cooling.

CHINOLINA.—QUINOLINE.

FORMULA: C_9H_7N . **MOLECULAR WEIGHT:** 128.74.

SYNONYM: *Leucoline*.

History and Preparation.—Quinoline is an artificial alkaloidal body obtained in the destructive distillation of quinine (or of cinchonine), with caustic potash. In 1842, by distilling quinine with potassium hydroxide, Gerhardt obtained this

body in an impure condition and named it *chinoline*, though Runge had before (1834) obtained a similar body from coal-tar and named it *leuoline*. These two bodies are now understood to be identical. Quinoline was first obtained pure by Williams in 1855. Zd. Skraup, in 1887, published his fruitful method of obtaining quinoline, by which way it may also be produced on a large scale. A mixture of strong sulphuric acid, glycerin, nitro-benzene, and aniline are heated carefully and gently to begin with, lest the reaction be too violent, and then water is added to dilute the mixture, which is then distilled in a current of steam to remove the nitro-benzene. Caustic soda is then added to the residue to alkalinity, and the quinoline thus liberated distilled with steam. The resulting product is fractionally distilled, dissolved in alcohol, and to this solution sulphuric acid is added, which precipitates an acid sulphate of quinoline. The yield is about three-fifths of the theoretical amount. By this process the sulphuric acid abstracts from glycerin the elements of water, converting it into acrolein, which then combines with aniline, the nitro-benzene acting as an oxidizer.

Description.—Pure quinoline is a mobile, oily liquid, colorless, or but feebly yellow, highly refractive, with a sharp, bitter taste, and a distinctive, aromatic odor. Its density is 1.084; its boiling point near 237°C . (458.6°F). It is hygroscopic, and exposed in the damp it forms a hydrate ($\text{C}_8\text{H}_7\text{N} \cdot 1\frac{1}{2}\text{H}_2\text{O}$), which, at 40°C . (104°F), becomes clouded. Alcohol, chloroform, ether, and benzin readily dissolve it, hot water partially. Carbon disulphide and wood alcohol mixes with it in all amounts. It is quickly turned brown by air and light, but decolorization may be effected by agitating it with solid potassium hydroxide, and subsequently slowly rectifying it. At ordinary temperatures it volatilizes, the odor resembling that of bitter-almond oil. It may be converted to a crystalline mass by means of a refrigerating mixture. Resin and camphor are soluble in it. When treated with fuming sulphuric acid it is changed into quinoline-sulphonic acid; this when melted with potassium hydroxide, forms oxyquinoline ($\text{C}_8\text{H}_6\text{NOH}$). German quinoline is a variable product. When quinoline is acted upon by amyl iodide, and then, with potassa or soda, a yellowish-green body, *cyanine*, is obtained. Quinoline salts are mostly crystalline, odorless, and respond to alkaloidal tests; its mineral acid salts are extremely hygroscopic.

Action, Medical Uses, and Dosage.—This agent has not fulfilled the claims made for it when introduced into medicine. While it has some antiperiodic and antipyretic properties, rendering it occasionally successful in *periodical fevers*, its bad effects upon the stomach—nausea, vomiting, and disordered digestion—more than offset any of its better qualities. A 5 per cent solution has been used with asserted success as a solvent for the false membrane of *diphtheria*, but the preparation has now fallen into disuse for this purpose. The tartrate and salicylate are given in doses of from 7 to 15 grains. Quinoline preserves anatomical specimens, though it extracts all the coloring matter. The following preparation is suggested: Quinoline 5 parts, common salt 6 parts, glycerin 100 parts, water 900 parts.

Quinoline Salts and Related Compounds.—**QUINOLINE TARTRATE.**—A nearly white, micaceous powder, having a sharp taste and pungent odor, soluble in cold water (80 parts), alcohol (150 parts), and ether (300 parts). It fuses at 125°C . (257°F).

QUINOLINE SALICYLATE.—A crystalline, white powder, easily soluble in alcohol, fatty oils, petrolatum, and ether, and less so in glycerin and water.

QUINOLINE HYDROCHLORATE.—Dissolves in alcohol, chloroform, and water, and is sublimable.

DIAPHATHERIN, Oxyquinaseptol Oxychinaseptol ($\text{C}_8\text{H}_6\text{SO}_3\text{H.OH}[\text{NC}_6\text{H}_4\text{OH}]_2$).—A bright, yellow, crystalline powder composed of oxyquinoline and aseptol. It is produced by combining 1 molecule of phenol-sulphonic acid with 2 of oxyquinoline (oxychinoline). Water and diluted alcohol readily dissolve it; alkalis and blood decompose it. It is claimed for it that it is a non-poisonous, non-caustic antiseptic, and in a 1 per cent solution is used upon wounds.

ANALGEN.—*Ortho-oxyethylana-monobenzoyle-amidoquinoline* ($\text{C}_{12}\text{H}_{11}\text{N}_2\text{O}_2$ or $\text{C}_7\text{H}_5\text{N}[\text{OC}_6\text{H}_4\text{NHCOC}_6\text{H}_5]$). This is a quinoline derivative prepared by a complicated method. It is a crystalline, white powder, soluble in alcohol, acids, and scarcely at all in cold, but more easily in hot water. It has been used in 15-grain doses to allay the pains of *rheumatism*. It is claimed to be antipyretic, antirheumatic, and analgesic. It colors the urine red.

OREXINE HYDROCHLORIDE.—*Phenylidihydroquinazoline hydrochloride* ($\text{C}_8\text{H}_7\text{NCH}_2\text{CH}_2\text{NC}_6\text{H}_5\text{HCL}$), *Phenylidihydrochinazolin hydrochlorate*. A quinoline derivative of complex character, introduced in 1890 as a remarkable appetizer, stomachic, and digestive. It is either a white powder, or in needle crystals soluble in water (1 in 13), and alcohol, but not in ether. It is pungent and bitter to the taste. Upon the Schneiderian membrane it acts as a powerful

irritant. The dose is from 4 to 8 grains, in wafers or capsules (not in pills), immediately followed by fluid to protect the gastric membrane from its irritant effects. It is said to increase the appetite, but reports concerning its value are much at variance. It is probably overrated. This compound is also known as *Orexin*.

CHINOL.—*Chinoline monohypochlorite* (C_6H_5NClO). An odorless, crystalline, white powder, practically insoluble in water, but quite freely dissolved by alcohol. Its taste is pungent, but not unpleasant. In doses of 3 to 5 grains it is employed as an analgesic and antipyretic, being applicable to cases in which antipyrin succeeds.

CHIONANTHUS.—FRINGE-TREE.

The bark of the root of *Chionanthus virginicus*, Linné.

Nat. Ord.—Oleaceæ.

COMMON NAMES: *Fringe-tree*, *Old man's beard*, *Snowdrop-tree*.

Botanical Source.—This shrub grows from 6 to 20 feet high, has oval or oblong, smooth, leathery leaves, opposite and veined. The flowers are in a dense,

pendulous panicle, the pedicels being long, filiform, and single flowered. The calyx-tube is very short, persistent, 4-parted, and small. The corolla is about 1 inch long, consisting of 4 very narrow, drooping, linear, snow-white petals; hence the name fringe-tree, by which it is generally known. The style is short, the stigma notched. The fruit is an oval, purple, fleshy drupe, with a bloom, and contains a bony, one-seeded nut.

History.—*Chionanthus* is one of our most striking and beautiful southern shrubs, and is often cultivated in gardens and parks for its ornamental beauty. We regard it as one of our most valuable indigenous remedies. The fringe-tree, as it is commonly called, grows from Pennsylvania to Georgia and Tennessee, thriving in sandy soils, in elevated situations, near

Chionanthus virginicus.

flat rocks, and along river banks. The tree, when in blossom (May and June), presents a beautiful appearance, being snow-white, hence its common names of *old man's beard*, *old man's gray beard*, *snowdrop-tree*, and *white ash*. It is also known as *poison ash*. The name *chionanthus* (pronounced kíō-nân'thūs) is derived from two Greek words, *chion* (snow) and *anthus* (flower, or blossom), hence, snow-flower. The bark of the root is the part used, and imparts its properties to water or alcohol.

Action, Medical Uses, and Dosage.—*Chionanthus* acts principally upon the abdominal glandular organs, and to some extent upon the venous system, relieving congestion. It is an alterative in the Eclectic meaning of that term. While its main action is upon the visceral glands, especially the blood-making organs, its influence is also quite marked in other secretive structures. Besides its pronounced catalytic properties, it is diuretic, tonic, and is said to be aperient and narcotic. It is exceedingly doubtful if the latter statement be true and its aperient property, if it possesses such, is the result of its cholagogue action.

Prof. King, in former editions of the *American Dispensatory*, states that in *bilious* and *typhoid fevers*, as well as in *obstinate intermittents*, the infusion of the bark of the root is efficient. While the remedy is now but very little used for these conditions, still some "old school" authors, as well as some trade catalogues, seem to have appropriated the above statements in regard to its use. Prof. King further states that it is an excellent tonic in "convalescence from exhaustive diseases," and that it also proves a good local application in *external inflammations*, *ulcers* and *wounds*. The use of an infusion of the bark of the root is directed, still it is doubtful whether such a preparation would be as efficient as an alcoholic form, for the resin, or the resinoid, the active constituent of the drug, is insoluble

in water. Goss states that the infusion is wholly inert. *Chionanthus* improves the appetite, aids digestion, promotes assimilation, and is a tonic to the whole system. It never produces catharsis, but ptyalism has resulted from its use.

Chionanthus has been successfully used in *mercurial cachexia*, *scrofula*, and *sypilis*, though we possess better agents for these classes of disease. Yet, if the patient be sallow, or yellow, and has hepatic pains, the remedy will prove a valuable accessory agent in hastening the cure.

It is for its prompt and efficient action in *hepatic derangements* that we most value fringe-tree preparations. If there is any one thing true in specific medicine, it is that *chionanthus* has a decidedly specific action in *jaundice*. The credit of having brought this remedy before the profession, for the purposes for which it is now used, belongs to the late Prof. I. J. M. Goss, of Georgia, who, in 1843, tested it on himself while suffering from an attack of *jaundice*, and reported the result in an eastern journal. Since then it has come to be the first remedy thought of for this complaint. Goss considered it the best remedy for all cases of *jaundice*, not dependent on gall stones. On the contrary, Prof. Scudder was high in his praise of it, even when *calculi* are present. He recommended it in 10 or 15-drop doses during the paroxysm, and also gave it to prevent a recurrence. *Nux* or *dioscorea* may be associated with it when called for, the former in atonic conditions, with broad, expressionless tongue, the latter in irritative states, the tongue being red, pointed, and elongated, with prominent papillæ. *Hypertrophy of the liver*, *chronic hepatic inflammation*, and *portal congestion* are speedily relieved by *chionanthus*. The remedy acts quickly, often removing in from 1 to 2 weeks, an icteric hue that has existed for months, and even years. *Jaundice* once cured by it is not apt to recur. There are two direct indications for the drug—*jaundice*, as evidenced by the yellowness of skin and conjunctiva; and soreness and pain, "hepatic colic," as pointed out by Prof. Scudder. The latter is by far the most direct indication. There is the dull, heavy pain in right hypochondrium, with a feeling of fullness and weight, deep-seated tenderness and soreness on pressure, occasional hectic flushes, light colored feces, sometimes diarrhoea with frothy, yeasty stools, and urine scanty and high colored.

These conditions, with the icteric hue of skin and conjunctiva, call for *chionanthus*. Sometimes the patient writhes in pain, can not find rest in any position. R Specific *chionanthus*, gtt. x, every half hour, and apply a cloth wrung out of hot water. In *dyspepsia*, with hepatic complications; in *irritative states of the stomach* from "high living," and the use of alcoholic stimulants; and in general *chronic inflammatory conditions of the duodenum*, and *ductus communis choledochus*, *chionanthus* serves a useful purpose. It is also a good remedy in *infantile dyspepsia*. *Rheumatic affections*, with soreness in the region of the liver, and a jaundiced condition, are ameliorated by this drug. Its tonic effects on the chylipoietic viscera render it a good agent in *general debility*. In *intestinal dyspepsia*, with *jaundice*, thin, watery, yeasty alvine discharges, with previous abdominal distension: R Specific *chionanthus*, gtt. v, every 2 hours.

Chronic splenitis and *nephritis* are conditions in which fringe-tree often proves a good remedy; also in *pancreatic disease*, inflammatory or otherwise. *Glandular diseases*, with evidence of imperfect waste, often call for its administration. *Chionanthus* is of utility in *uterine* and *ovarian congestion*, when the usual hepatic symptoms calling for it are present. If there be fullness and bearing down in the pelvic viscera, especially a desire to frequently evacuate the rectum, combine it with specific *helonias*. R Specific *chionanthus*, specific *helonias*, aa flj; aqua q. s., ʒiv. Mix. Sig. Teaspoonful every 2 hours.

In female disorders it may also be combined with *gelsemium*, *macrotys*, or *pulsatilla*, when indications for these drugs are present. Some cases of *uterine leucorrhœa* are promptly benefited by it. Cleansing injections should be employed at the same time. As a poultice it will be found an excellent local application in *external inflammations, ulcers, and wounds*.

Dose, from $\frac{1}{2}$ fluid ounce of the infusion to 2 fluid ounces, repeated several times a day, according to its influence upon the system. The usual dose of specific *chionanthus* (the best preparation), is 10 drops in water every 3 hours. *Chionanthin*, the so-called concentration, is of little value and is but seldom used. It was first prepared by Prof. Goss.

Specific Indications and Uses.—Dirty, sallow skin, with expressionless eyes and hepatic tenderness; an icteric hue, with or without pain; hepatic colic; intense pain from liver to umbilicus, attended with nausea and vomiting and great prostration; pain in epigastrium and right hypochondrium, simulating colic, sometimes extending to the abdomen; jaundice, with itching skin and thin, light-colored, watery stools; tympanites; colic, with green alvine discharges; urine stains the clothing yellow.

CHIRATA (U. S. P.)—CHIRATA.

"The entire plant, *Suertia Chirata*, Hamilton"—(U. S. P.). (*Ophelia Chirata*, Grisebach; *Agathotes Chirayta*, Don; *Gentiana Chirayta*, Roxburgh.

Nat. Ord.—Gentianaceæ.

COMMON NAMES: *Chirata*, *Chiretta* (U. S. P., 1870), *Chirayta*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 183.

Botanical Source.—Chirata is an annual, with a branched root, and a smooth, erect stem, about 2 or 3 feet high, the middle and lower portion being round, the upper 4-angled, with a prominent decurrent line at each angle. The branches form panicles, the leaves being lanceolate, or ovate-acuminate, and cordate at the base, smooth, entire, acute, sessile, clasping, and marked with 3, 5, or 7 nerves. The flowers are yellow, rotate, 4-parted, numerous, and peduncled. The stamens are 4, the style single, and the stigma 2-lobed. The fruit is a many-seeded capsule.

History and Description.—This annual plant is a native of North India, growing in the mountainous districts, and has been held in considerable esteem as a medicine by the Hindus. The whole plant is gathered about the flowering period, or just as the capsules have fully formed (*Pharmacographia*). The whole plant, including the flowers, is very bitter, with the exception of the woody portions of the stouter stems. The U. S. P. thus describes the medicinal article: "Root nearly simple, about 7 Cm. (2½ inches) long; stem branched, nearly 1 meter (about 40 inches) long, slightly quadrangular above; containing a narrow wood-circle and a large, yellowish pith. Leaves opposite, sessile, ovate, entire, 5-nerved. Flowers numerous, small, with a 4-lobed calyx and corolla. The whole plant smooth, pale-brown, inodorous, and intensely bitter"—(U. S. P.).

Chemical Composition.—The ash of chirata yields carbonates and phosphates of calcium, potassium, and magnesium. Tannin is almost entirely absent. A crystalline, yellow, waxy body in small amount, as well as the ordinary plant constituents, abound. Two bitter principles occur, discovered by Höhn in 1869. These bodies are *ophelic acid* ($C_{15}H_{20}O_{10}$), and *chiratin* ($C_{28}H_{48}O_{13}$), the former being in largest amount. *Ophelic acid* is a hygroscopic, non-crystalline, yellow, viscid body, having an odor faintly suggestive of gentian, and an acidulous, bitter taste which is persistent. Water, ether, and alcohol dissolve it. Basic lead acetate precipitates it yellow. *Chiratin* forms an insoluble compound with tannic acid (*ophelic acid* does not), and may be removed by means of that acid. It is a pale-yellow, indistinctly crystalline powder. Alcohol, ether, and warm water dissolve it, and yet, though hygroscopic, it is not readily soluble in cold water. Its taste is extremely bitter, and its behavior to litmus neutral. Boiled with hydrochloric acid it splits into *ophelic acid*, water, and *chiratogenin* ($C_{15}H_{24}O_3$), a bitter, amorphous, brown body, not soluble in water, but freely so in alcohol. It is unaffected by tannin.

Substitutes and Adulterants.—Several species of *Ophelia* and related plants go by the name of *chirata* in India. These are designated by the natives as hill (*puharree*) *chirata*, sweet (*meetha*) *chirata*, purple (*ooda*) *chirata*, and southern (*duk-hunee*) *chirata*. *Chota chiretta*, or *small chiretta* is the product of *Slevogtia orientalis*, Grisebach. The species of *Ophelia* referred to above are the *O. angustifolia*, Don (less bitter than *chirata*); *O. elegans*, Wight; *O. densifolia*, Grisebach; *O. multiflora*, Dalz; *O. pulchella*, Don. These all possess, more or less, the bitter tonic virtues of *chirata*. Besides these are included *Andrographis paniculata*, Wallich, and a few species of *Exacum* (*Pharmacographia*).

Action, Medical Uses, and Dosage.—This drug possesses the tonic properties of gentian and similar bitters. It is valued in Hindustan, where it is much

employed in *urinary complaints* with uneasiness in the region of the kidneys, frequent urging to urinate, which is accomplished with difficulty, and in cases of *uric acid deposits*. It is a remedy also for convalescence from exhausting sickness, and for atonic and nervous forms of *dyspepsia*. Dose of *chirata*, 10 to 20 grains; fluid extract, 10 to 20 minims; infusion (3ss to boiling water Oj), flʒi to flʒii, 3 times a day.

CHLORAL (U. S. P.)—CHLORAL.

FORMULA: Chloral, C_2Cl_2OH . MOLECULAR WEIGHT: 147.01.

FORMULA: Chloral hydrate (CHLORAL, U. S. P.), $C_2HCl_2O + H_2O$. MOLECULAR WEIGHT: 164.97.

SYNONYMS: *Aldehydum trichloratum*, *Hydrous chloral*, *Chloral hydrate*, *Trichloraldehyde hydrate*.

History and Formation.—Chloral, the anhydrous compound (for the hydrate or U. S. P. chloral, see below) was discovered in the year 1832, by Liebig (Gmelin's *Chemistry*, Vol. IX), who obtained it by passing chlorine through absolute alcohol. In 1845, Staedeler procured it by the action of nascent chlorine upon various organic substances, and also by the distillation of starch, binoxide of manganese, and hydrochloric acid. It excited but little interest until the year 1869 (*Pharm. Jour.*, 1869, p. 150), at which period hydrate of chloral was introduced to the medical profession by Dr. Oscar Liebreich, of Berlin. Shortly afterward, in the same year, both Mr. Hanbury and Dr. Richardson brought specimens before the English Medical and Therapeutical Associations, and subsequently its introduction to other countries soon followed. Many long names have been given to it by chemists, as *aldehyde of trichlorotretted acetic acid*, *trichloraldehyd*, *trichlormethyl-hydrocarbonoxyd*, *trichloracetyloxydhydrat*, but which have not been and are not likely to be adopted by physicians.

Preparation and Description.—Chloral occurs as a colorless fluid, oily in appearance, and of the specific gravity 1.518, at 0° C. (32° F.), and 1.502, at 18° C. (64.4° F.). Its boiling point is about 99° C. (210.2° F.). At ordinary temperatures it evolves a pungent vapor that is very irritating to the eyes. It has a disagreeable taste, is soluble in less than its weight of water, and in 4 times its weight of chloroform, and is freely miscible with ether. Chloral dissolves phosphorus, sulphur, bromine, and iodine, the latter solution giving a very rich purple color. Heat facilitates their solution. Anhydrous metallic oxides have no action upon it. It unites with water to form a hydrate, and with alcohol to form an alcoholate. The formula for chloral is C_2Cl_2OH , and its modern name is *Trichloraldehyde*. It is made by passing chlorine gas into anhydrous alcohol. The word *chloral* is derived from the first syllables of chlorine and alcohol (*chlor[ine] al[cohol]*) (a similar word-creation is *aldehyd*).

The reaction which produces chloral is very complex. (For a lucid exposition of the reactions involved see Attfield's *Chemistry*, 1894). In practice, it is customary to first reduce the temperature of the alcohol through which the chlorine passes, then, as the solution thickens, to apply heat until hydrochloric acid gas ceases to be evolved and chlorine appears, when the flow of chlorine is discontinued. The crude chloral alcoholate, together with other incidental products of the reaction, is now agitated with sulphuric acid, and then distilled; it is now purified, by again distilling it, from a small portion of quicklime, being careful not to have an excess of lime, or the chloral will be destroyed. Chloral is decomposed by solutions of caustic alkalies, yielding a formate of the base, and chloroform, and it is thought by some, that to this decomposition of chloral in the alkaline fluids of the body, gradually producing chloroform, its influence upon the system is due. It is not employed in medicine, and is of interest only from the fact that it unites with one molecule of water to form chloral hydrate.

Chloral can be distilled unchanged, but gradually becomes thicker, and occasionally changes into an insoluble modification with development of heat; this modification presents a porcelain-like mass, termed *metachloral*, which, though isomeric with the fluid chloral, is insoluble in water, alcohol, or ether, but which is reconverted into chloral by distillation; contact with water gradually changes it into the crystallized hydrate of chloral. The aqueous solution of chloral has

no action upon vegetable colors; oxides of silver or mercury do not affect it; concentrated sulphuric acid deprives it of water and separates the anhydrous crystals. The foregoing chloral must not be confused with the official preparation, which is chloral hydrate, and now passes under the name CHLORAL (*U. S. P.*).

CHLORAL (*U. S. P.*). **CHLORAL HYDRATE.**—*Hydrate of chloral.* *Preparation:* Chloral hydrate ($C_2Cl_2H_2O_2$, or $C_2Cl_2.OH.H_2O$, or according to *U. S. P.*, $C_2HCl_3O + H_2O$) is prepared by mixing chloral with the proper amount of water, and then pouring the solution, in thin layers, into a porcelain or glass dish; this is covered and placed in a cool situation. Heat is liberated, and the liquid solidifies, forming a mass of pure dazzling whiteness, composed of minute, transparent, or semi-transparent crystals, or crystalline plates of chloral hydrate. These have a sweet, ethereal odor, a greasy feeling when rubbed between the fingers, and a pungent taste. According to Versmann, 100 parts of water dissolve 360 parts of chloral hydrate. Prof. J. U. Lloyd, in *Supplement to American Dispensatory* (1880), writes: "When the therapeutical use of chloral hydrate was first agitated in this country, the writer was obliged to prepare the article in a limited way, until a supply could be obtained from abroad. Few persons can realize, without actual experiment, the care that is necessary, and the large amount of chlorine required for the production of even a limited quantity of this agent. It has been calculated that 1 pint of alcohol will require at least 316 gallons, or 73,233 cubic inches of chlorine, and there will be formed about 396 gallons or 91,542 cubic inches of hydrochloric acid gas."

Description and Tests.—**CHLORAL (*U. S. P.*), Chloral hydrate.** "A crystalline solid, composed of trichloraldehyde or chloral with 1 molecule of water. It should be kept in glass-stoppered bottles, in a cool and dark place. Separate, rhomboidal, colorless and transparent crystals, having an aromatic, penetrating, and slightly acrid odor, and a bitterish, caustic taste; slowly volatilized when exposed to the air. Freely soluble in water, alcohol, or ether, also in chloroform, benzol, benzin, carbon disulphide, fixed and volatile oils. It liquefies when triturated with about an equal quantity of camphor, menthol, thymol, or carbolic acid. When heated to about $58^\circ C.$ ($136.4^\circ F.$), it melts, forming a liquid having a specific gravity of about 1.575, which, at a higher temperature, should not evolve inflammable vapors. Liquefied chloral solidifies to a crystalline mass between 35° and $50^\circ C.$ (95° and $122^\circ F.$). Chloral is decomposed by caustic alkalies, alkaline earths, and ammonia, chloroform being formed, and a formate of the base produced. A freshly prepared, aqueous solution of chloral is neutral, but gradually acquires an acid reaction. A neutral alcoholic solution remains neutral permanently. Chloral should be dry, and not readily attract moisture in dry air. A solution of chloral (1 in 20) in diluted alcohol, acidulated with nitric acid, should remain unaffected by silver nitrate T.S. (absence of hydrochloric acid and chlorides. If 1 Gm. of chloral be dissolved in 2 Cc. of warm water, mixed with potassium hydrate T.S. in slight excess (about 8 Cc.), the mixture filtered, and a portion of the clear filtrate treated with iodine T.S. until it is yellowish, no yellow, crystalline precipitate (iodoform) should appear within $\frac{1}{2}$ an hour (absence of chloral alcoholate)"—(*U. S. P.*).

Its alcoholic solution is neutral, and when the chloral is pure and recent, the aqueous solution is also, but with the chloral of commerce, the latter solution usually exhibits a slightly acid reaction. Chloral hydrate dissolves in glycerin, and this solution has the property of dissolving many alkaloids that are nearly or quite insoluble in that menstruum (glycerin). This property of dissolving alkaloids, insoluble in water, is also possessed by the aqueous solution of chloral hydrate, and both this and the solution of chloral hydrate in glycerin, was recommended for the purpose by Mr. Fairthorne. By placing together equal weights of camphor, and chloral hydrate, a clear liquid results, which is decomposed by water into the original substances. It is dissolved by alcohol, glycerin, chloroform, ether, and the fixed oils. This liquid was named CAMPHORATED CHLORAL, but is rarely used.

With aqueous solutions of the caustic alkalies, chloral hydrate is entirely resolved into alkaline formates and chloroform. Thus, with hydrate of sodium, the reaction will be as follows: $C_2Cl_2H_2O_2 + NaOH = CHCl_3 + NaCHO_2 + H_2O$. It was this property, which chloral hydrate possesses, of producing chloroform when

in contact with an alkali, that led Liebreich, in 1869, to reason that it might be used as a remedial agent. In 1873, it was found that chloral hydrate would prevent decomposition of albuminous substances, such as milk, meat, and animal matters generally (*Comptes Rendus*, Feb., 1874, and *Pharm. Jour. and Trans.*, 1876), and it is at present used in solution for injecting anatomical subjects. Chloral hydrate solution rendered slightly alkaline with carbonate of sodium, entirely prevents the coagulation of blood (Ore).

According to Meyer and Hafter, 165.5 grains of chloral hydrate consume 1000 Cc. of normal sodium solution. Theoretically, chloral hydrate should yield 72.2 per cent of chloroform, when agitated with slight excess of strong solution of caustic alkali; but, practically, the yield is generally between 70 and 72 per cent, often below 70 per cent with commercial chloral hydrate. Chloral hydrate should never present a pink appearance, and should dissolve in concentrated sulphuric, hydrochloric, or nitric acids, with formation of colorless solutions, and, with the latter acid, should not evolve red fumes. When pressed between two pieces of filtering or blotting paper, chloral hydrate should produce no stain.

When an aqueous solution of chloral hydrate is acidulated with diluted sulphuric acid, and the solution faintly tinged with a few drops of solution of permanganate of potassium, it should not decolorize in several hours. If the solution becomes quickly colorless, the chloral hydrate has partly decomposed.

For therapeutical purposes hydrate of chloral must be strictly pure, as impurities which occasion irritating and even serious effects are by no means rare. It must form a hard, white, or transparent crystalline mass, be completely soluble in water, not smell of chloride of carbon or hydrochloric acid, but retain the peculiar penetrating odor of chloral. It would be dangerous to employ hydrate of chloral contaminated by chlorous acetylene, chloride of carbon, and other incidental products, and hence great care must be observed in its preparation.

Action and Toxicology.—Prof. Liebreich first experimented with chloral upon frogs and rabbits, and then upon human subjects, using it internally, and by subcutaneous injections. M. Demarguay, who experimented with it, in a communication to the Academy of France, observed that it produces a well-marked soporific effect upon weak patients, the duration of which effect is in proportion to the debility of the patient; that the sleep induced by it is calm, being disturbed only in patients suffering from acute pains, and that it may be given in doses of from 1 to 5 grammes (15 to 77 grains). He states that the breath of the person smells of it. He does not believe with Prof. Liebreich that it is decomposed into chloroform and formate salt in the blood, but agrees that it is the most rapid of all the then known soporifics. In fact, there are several reasons why Liebreich's theory of the action of chloral, being due to the formation of chloroform, are untenable, though the point is still in dispute, and the majority of investigators seem to think that, while some chloroform may be formed, the whole of the action of chloral can not be attributed to that agent alone. Among these reasons are the following: After the administration of chloral, chloroform can not be detected in the blood, excretions, or exhalations; the effects of chloral are different from those of like amounts of chloroform; chloral is less anæsthetic, but greatly and positively more hypnotic than chloroform; and, lastly, chloral crystals have been detected in the blood, while the urine has yielded chloral decomposition products.

Dr. B. W. Richardson, of London, who has also experimented with this agent, sums up its effects as follows (*Med. Times and Gaz.*, Sept. 4, 1869): Hydrate of chloral can safely produce deep and prolonged narcotism; during a portion of the period of this narcotism, there may be complete anæsthesia with absence of reflex actions, and a condition in which every kind of operation fails to call forth consciousness. There are also intervals of apparent exalted sensibility, and during the narcotism there is invariably a reduction of temperature; in the transition from drowsiness to stupor there is no stage of muscular excitement, but in birds, vomiting. It produces muscular relaxation, which extends to the muscles of volition, to the iris, and to the muscular arterial system, and, from the condition of the muscles after death we may infer that this paralysis is in part due to change within the muscular structure itself; its action on the nervous system is primarily on the sympathetic ganglia, afterward on the cerebrum, and, lastly, on the heart; when recovery takes place it is followed by no bad results; in fatal cases the

functions destroyed are (1) the cerebral; (2) the voluntary muscular; (3) the respiratory; (4) the heart; in small proportions it somewhat arrests the coagulation of the blood; in large quantities it stops the process of coagulation altogether, destroys the blood corpuscles and produces general destruction of blood, but the dose required to produce extreme narcotism need not be so large as to lead to serious derangement of the blood. Dr. Richardson believed the effects of chloral to be the result of the action of chloroform.

Dr. Wm. A. Hammond (*Med. Record*, N. Y., 1870, p. 499), from some careful observations, in numerous experiments made by himself, believes he has clearly demonstrated (1) that pretty large doses of the chloral hydrate produce at first congestion of the brain, probably from vaso-motor paralysis accompanied by functional exaltation; (2) that this stage is soon followed by one of cerebral anemia (perhaps from cardiac and cerebro-spinal paralysis), with the resultant drowsiness deepening into profound sleep; (3) that small doses produce only the congestion and excitement, with no subsequent hypnotic effect. He is satisfied that it is a remedy of real value in many nervous diseases. M. Bouchut (*L'Union Médicale*, Nov. 13, 1869) considers hydrate of chloral a powerful sedative of the motor and sensory nervous system, the doses of which should not exceed 5 grammes (77 grains) for adults, and 2 grammes (31 grains for children). Its effects are more prompt when given by rectum than by mouth, and, when injected subcutaneously, it occasions formidable eschars. When the agent is pure, and in the state of solid hydrate its results (most calm hypnotism and almost absolute insensibility) are rapid, manifest, and energetic, its action lasting longer than when chloroform is employed.

Dr. Jules Worms, after a series of experiments, concludes that hydrate of chloral dissolved in 10 parts of water can be drank without any inconvenience to the amount of 10 grammes (154 grains); the effect is felt with $1\frac{1}{2}$ or 2 grammes (23 or 31 grains), but there are some obstinate cases which require a dose of 2 or 3 grammes; in about 10 or 15 minutes after the digestion of the hydrate, a calm, often profound sleep, occurs without any modification in the temperature of the body, in the regularity of the pulse or the respiration, and which continues for 7 or 8 hours, and the awaking from which is not accompanied by headache, nausea, torpor, or other disagreeable sensations.

We should here observe that, unless the chloral hydrate is pure, it may not only fail in producing some of its beneficial effects, but it may likewise occasion serious symptoms; and it is by no means improbable that the unexpected deaths that have sometimes followed its internal administration in medium doses were due to the impurity of the chloral employed.

That chloral hydrate is a powerful agent for good or evil, accordingly as it is employed, is now well recognized. Briefly, we shall here give the action of the drug as now understood. Chloral is distinctly antiseptic, and animal structures may be preserved by it for a considerable time. Applied to the skin and kept in contact, it will cause redness and inflammation, and upon the mucous membranes it occasions pain. Under certain conditions it is vesicant. It is powerfully irritant to denuded surfaces and wounds. Taken internally, the taste is pungent and hot, and the salivary flow is greatly augmented. At first a cooling sensation is excited in the stomach, but this is followed by warmth, and if in moderate amount the appetite is stimulated without any ill after-effects. If the amount be large, however, gastric irritation, with nausea and vomiting, is apt to occur. Injected into the rectum it causes heat and irritation, and subcutaneously produces pain and sloughing. In ordinary or even large amounts, it is thought to have but little effect upon the blood. The clots found after death from chloral are now attributed to "stasis of the blood in the vessels from lack of propelling power in the heart and arteries" (Jeançon). Chloral fulfils three indications; it controls pain, though less effectually than opiates, it subdues spasm, and it induces sleep. The effects are quite uniform, though occasionally an individual will be found in whom the ordinary hypnotic doses fail to cause sleep, and such persons are then likely to have headache and become delirious under its action. A very short stage of excitement precedes its secondary action when a hypnotic dose (15 to 30 grains) is administered, but this is followed by a calm, refreshing slumber, remarkably like natural sleep, without dreams, and the patient awakens

in about 3 to 6 hours without experiencing any of the unpleasant after effects, either of the head, stomach, or bowels, so common to opium and some of the other narcotics. While large doses of chloral produce deep narcotism, such an effect as is produced by the hypnotic dose can not be called distinctly narcotic, for the patient may be aroused to take nourishment, or even to respond to Nature's calls, and fall to sleep again as if nothing had disturbed his slumbers. Occasionally an individual may be found who, though asleep under its use, will be disturbed by hallucinations and dreams, and when awakened will suffer from nervous and gastric symptoms. Chloral is not a true anodyne in the sense that the morphine salts are, and allays the sensibility to pain only when given in very large doses—amounts sufficient to produce abolition of the cerebral functions. During sleep under chloral the face is somewhat flushed, and the pupils slightly contracted, becoming normal upon waking; the pulse may be unaffected or very little slowed, while the respiration is wholly undisturbed. The sleep of chloral is produced by the cerebral anemia caused by the drug. Large, dangerous doses of chloral induce a profound narcotism with muscular relaxation, reduced temperature, and loss of sensation and reflexes. Death from lethal doses is preceded by all the symptoms of syncope. The breathing becomes slow and shallow, the pulse is weak, rapid, thready, and fluttering; a sinking sensation is experienced; complete muscular relaxation ensues, and both sensibility and reflexes are abolished; the pupils first contract, then dilate; the extremities are cold and paralyzed, the surface pallid, and the countenance partially livid. Death is preceded first by the suspension of the cerebral functions, which is followed by respiratory paralysis, and lastly, by paralysis of the motor ganglia of the heart, though some cases result directly from sudden cardiac paralysis, especially where fatty degeneration of that organ exists. The heart is arrested in diastole in acute chloral poisoning, and the patient dies anesthetized and paralytic. Prof. J. A. Jeançon (Scudder's *Materia Medica*), thus states the action of chloral: "Chloral hydrate acts primarily and directly upon the gray substance of the medulla oblongata, some gray substance of the cortex, and upon the posterior tubercular quadrigemina. The respiratory centers are primarily affected, and from them a reflex action is exerted upon depressory fibres of the pneumogastric of the heart, causing a reduced pressure of the blood in the arterial system, when moderate doses are taken. In large doses the psycho-motor and motor fibres of the gray mass of the cortex of the middle cerebral lobe are there included in its action, which is then intensified, the circulation and respiration much affected, and complete muscular relaxation produced. The center of common sensation is temporarily paralyzed. The sensation of the skin and the vegetative functions of the body are but imperceptibly disturbed."

While the blood is ordinarily but little affected by chloral hydrate, there are cases in which a blood lesion is produced by the drug, death being preceded by a scorbutic state with eruptions, purpuric spots, enlarged and ulcerated gums, prostration, and collapse. Chloral has produced an erythematous eruption, followed by desquamation, a rash most likely, it is said, to be produced in children, and in the debilitated and cachectic, particularly those suffering from nervous disorders. It is most liable to occur when alcohol and chloral are taken at the same time.

Chloral hydrate is taken by some individuals until the chloral habit is formed. *Chronic chloralism* presents serious disturbances, the chief among which are the following: The chloral habitué is a voluble talker, speaking in a quick and excitable manner; the eyes are irritable and hyperemic, though brilliant. Tinnitus, sudden dizziness, wakefulness with irritability and great nervous unrest, are experienced, and the victim can not sleep without the hypnotic effects of the drug. Mental hebetude, melancholia, loss of memory, hallucinations, and maniacal excitement, are among the nervous symptoms. The person is easily tired and has no capacity for exertion; efforts at work are prostrating, and all the voluntary movements are irregular and uncertain. There may be no appetite, or if present it is always capricious, digestion is very feeble and attended with dyspnoea when the stomach is full, and the stools light and pasty, showing a lack of bile, though the latter stains the urine, which may also contain albumen. The heart-action becomes progressively feeble and irregular, and rashes and purpuric spots may appear on the skin.

Death from chloral reveals, upon post-mortem examination, meningeal, cerebral, spinal, and pulmonary congestion, with a distended right heart.

The treatment of *acute chloral poisoning* is similar to that for narcotics. As a peculiar coldness pervades the victim, artificial heat should be applied to the extremities, and to the præcordium. Alcohol in repeated small doses may be given by the mouth, rectum, or subcutaneously. Friction, flagellation, faradization, or galvanism to the diaphragm, cold applications to the head and neck, artificial respiration, and coffee or caffeine to sustain the heart, should be administered. Atropine, digitalis, and amyl nitrite may be used for the same purpose. Strychnine, hypodermatically, for its effects upon the spinal cord should be given in $\frac{1}{4}$ -grain doses about every half hour. *Chronic chloralism* is best treated by gradually lessening the quantity of the drug consumed; nourishing and easily digested food, and tonics, particularly the chalybeates, should be exhibited. Cathartics should be occasionally resorted to. Cannabis indica is said to aid the stomach, and lessen the appetite for chloral. As calmatives to the nervous system, lupulin and hyoscyamus may be used, while strychnine is indicated as a nerve stimulant. That strychnine was an antidote to chloral was announced by Liebreich (*Comptes Rendus*, Feb., 1870), basing his conclusions upon experiments performed upon rabbits.

Medical Uses and Dosage.—Chloral is one of the most important remedies in the materia medica. With but few remedies is it so absolutely essential to know the proper indications for its use, for if used when contraindicated, it takes but very little of chloral to kill. It is contraindicated always when there is an anemic condition of the brain. It can not safely be given to old toppers, nor should it be used where the heart-walls are thin or where fatty degeneration of the organ is established. All cases of marked depression are warnings not to give chloral. On the other hand, when indicated, no remedy is more useful nor more satisfactory in its results. An *active hyperemic state of the brain* is an indication for chloral, and particularly if there be *sleeplessness* from nervous excitement. Its use here is the same as that of potassium bromide, which it exceeds in efficiency. If sleeplessness be due to pain, it is less efficient than opium. As before stated, three important indications are fulfilled by chloral. It produces sleep, relaxes spasm, and to a certain extent relieves pain. In all cases of *sleeplessness*, and more especially when this condition is the result of brain exhaustion, from previous mental or moral excitement, or in sleeplessness and excitement where opium or other narcotics are objectionable, as in *acute mania*, *delirium tremens*, *hysteria* of plethoric females, etc., chloral is indicated, but it should be remembered that it is not to be administered to persons greatly enfeebled, nor to those who are subjects of any dyspnoic or cardiac affections.

While chloral is a dangerous remedy in the depression of confirmed inebriates, it is of value in *delirium tremens*, where opium would be inadmissible. The condition admitting it is one of over-stimulation of the brain and nerve centers, while in the opposite condition, where the brain suffers from a want of stimulation, it is inadmissible, while opium and alcohol act beneficially. Use chloral where there is great excitement, dry skin and tongue, increased temperature, and flushed face. The pale face, feeble circulation, muscular relaxation, and surface bathed in perspiration, are contraindications to its employment. In properly selected cases chloral hydrate may be used to relieve pain in *neuralgia*, *cancer*, *rheumatism*, *toothache*, *lead colic*, pain from the pressure of *tumors*, etc., on nerve trunks, *painful disease of joints*, and in *painful minor surgical operations*; in some instances, however, the pain seems to be intensified after the transient and anodyne effects have passed off; to reduce the animal heat in *fevers*, and especially those following *surgical operations* when the temperature is increased and the patient is excited or delirious; to produce extreme muscular relaxation in medical and surgical cases, where it is required to overcome resistance or *spasm*; in *tetanus*; passage of *biliary calculi*, it likewise dissolves these calculi; *vesical and renal calculi*; *strangulated hernia*; *reduction of dislocations or fractures*, etc. It has also been successfully used in severe *sea sickness*, *vomiting of pregnancy* (enema), *vesical catarrh*, *metritis*, *consumptive cough*, *puerperal peritonitis*, *phlegmasia dolens*, *gastralgia*, *enteralgia*, *nervous asthma*, *laryngospasmus*, etc. According to Dr. A. Jacobi, its use is contraindicated in gastric ulcerations, as the remedy is slightly caustic, and in catarrhal or ulcerative affections of the larynx, in which cases it produces pain and cough. It is a

prompt remedy for *hiccough*. For *idiopathic tetanus* it is one of the best known remedies. It should be used when the temperature is high, giving 30 grains at bedtime, repeated if necessary at midnight. Sustaining food, as eggs and beef tea, should be administered freely. While this does not lessen the severity of the spasms, they become much less frequent. Like all other treatment, it will often fail. As the chief danger from *strychnine poisoning* lies in the convulsions produced, the antispasmodic power of chloral renders it valuable as an antidote to that poison, though large doses are required, and if great care is not exercised lethal effects may be produced by the large doses of the antidote employed.

During *parturition*, chloral hydrate, in doses of from 15 to 30 grains, repeated every half hour or hour, and continued no longer than is necessary to effect the desired result, is stated to have been useful in regulating uterine contractions, and lessening their severity, in favoring dilatation of the os, and in soothing undue nervous and mental excitability. It is an efficient remedy for *after-pains*. By those who have employed it in *eclampsia*, it is considered one of the best agents for overcoming the convulsions, although instances of failure have occasionally occurred; in this malady it is administered in doses of 10 or 15 grains, repeated as required, every 10, 15, or 20 minutes; and in severe cases, from 30 to 60 grains in solution may be employed as a rectal enema. In *epilepsy*, *chorea*, *pertussis*, and *paralysis agitans*, although not effecting recovery, it greatly lessens the severity of the paroxysms, as well as of muscular movements. One part of chloral hydrate dissolved in 6 parts of distilled water, and administered in fluid drachm doses every half hour, has frequently proved advantageous in *hemicrania*, as well as in *retention of urine*; in these cases, after sensations of relief have been experienced, the intervals between the doses should be extended to every 2 hours, for the last three or four periods of administration. Occasionally the headache is said to be more severe after the effects of the chloral have subsided. Probably the cases were not well selected. Alone or combined with specific hyoscyamus it has relieved the wretched *headaches of the menopause*. Ten grains of the drug in solution with 10 drops of henbane, are given every hour until sleep is induced.

Prof. R. L. Thomas uses chloral extensively in the *gastro-intestinal diseases of children*, with nausea and uncontrollable vomiting, when the condition depends on cerebral hyperemia. Small doses are employed, from 1 to 4 grains to 2 ounces of water or syrup, and a teaspoonful of the mixture administered every half hour or hour, as indicated. This use of chloral in this manner, is, so far as we are aware, original with Dr. Thomas. Prof. Scudder recommended 1-grain doses of chloral with hydrastine (berberine), in *irritable dyspepsia*. A rather novel use of chloral is reported in Webster's *Dynamical Therapeutics*, in which a physician claims to have cured two cases of *albuminuria* by rectal injections of chloral. One was a much debilitated woman whose condition developed after confinement; the other an Irishman "in extremis" from what appeared to be all the symptoms of "Bright's disease." The urine was scanty and albuminous, and chloral dissipated the urgent symptoms, while the augmented flow of urine was maintained by *nux vomica* and *digitalis* alternately administered.

As a local application, chloral hydrate has proved serviceable in several affections. Equal parts of chloral and distilled spirit of horseradish root, applied upon the affected parts by means of a soft sponge probang, every day, or every other day, has proved efficient in the *ulitis* of pregnant women; before applying it, the mouth should be cleansed, and any excess of tartar on the teeth be removed. It produces a slight degree of pain, and leaves a superficial, whitish eschar, which disappears after some hours. Finely powdered chloral hydrate sprinkled upon the surface of a Burgundy pitch plaster, and this applied over painful parts, has been found effectual in *lumbago*, *sciatica*, *pleurodynia*, and *intercostal neuralgia*. The plaster must be allowed to remain upon the part for 1 or 2 days, or until the skin beneath becomes covered with small vesicles filled with a limpid serosity; the plaster is then removed, each vesicle opened with a needle, and the whole covered with simple cerate spread upon a soft cloth. They become speedily healed. In *scald-head*, *baldness*, *dandruff* (*pityriasis*), and especially in obstinate, indolent *ulcers*, the local application, daily, of a solution of chloral hydrate, 10 or 20 grains in distilled water, 1 fluid ounce, will be found highly efficient; some smarting may follow each application. A weaker solution (1 in 100) will be

advantageous as a palliative and antiseptic in *ulcerated cancer of the breast, cancer of the uterus*, in *suppurating cavities, diphtheritic and gangrenous surfaces*, also to remove the offensive odor in *ozæna* (1 in 300), as well as that which emanates from the axillæ and feet (1 in 150) of certain persons. It may be applied on lint, or be used as a wash, by injection or by spray. A solution of chloral hydrate (30 grains to 1 ounce of water) will often prove serviceable as a local application to painful *bunions and chilblains*. One part of chloral and 16 parts of Carron oil (equal parts of lime water and linseed oil), form a mixture that has acted promptly and efficiently in *burns and scalds*. Camphorated chloral is an efficient topical application to painful parts.

Prof. Locke regards it a valuable antiseptic in *diphtheria*. He recommends a solution of from 20 to 25 grains of the salt in 1 ounce of glycerin, the solution to be painted upon the false membrane, the removal of which it promotes, as well as overcoming the disagreeable stench. *Itching* of the mucous surfaces is relieved by a weak solution of chloral (2 to 5 grains to 1 ounce of water).

Chloral is efficient as an injection (1 to 2 per cent) in *gonorrhœa*. A weak solution (7 grains) in brandy and water (1 ounce), is reputed an efficient lotion in the *night-sweats of consumption*, while a solution of 1 part in 100 of water is reputed a good surgical application in *indolent, gangrenous, or cancerous ulcers*, etc. *Erectile tumors and varicocèle* have been cured by an injection of a 10 per cent solution, though this method is by no means free from danger.

Chloral has a limited use in *ear affections*. It may be used to destroy *granulations of the tympanic cavity*, when there is an excessive purulent discharge. A 5 per cent solution is preferred. It may also be employed to destroy the base of the pedicle after the removal of *polypi*. Locally applied, chloral-camphor will mitigate the pain of *mastoid disease*, while the hydrate, given internally in doses of from 2 to 5 grains, every 2 hours, will sometimes allay the pain from *acute catarrh of the middle ear*.

Chloral hydrate is not used in subcutaneous injection (except in *strychnine poisoning*), as its action is too irritating and apt to be followed by troublesome abscesses, and should it be injected into the veins, its influence upon the heart and lungs is of a dangerous nature. Internally, for an adult, its ordinary dose varies from 10 to 30 grains, to be repeated every 1, 2, or 3 hours, as indicated; children, who stand chloral better than adults, also require much less, say, as many grains for a dose as there are years of the child's age. The dose, however, may vary from 5 to 10 grains as a hypnotic, which, in severe cases, may be increased to 20 or 30 grains. Liebreich recommends 7 grains as the dose for children; for adults from 25 to 30 grains, where short intervals of sleep are required, and repeated every 2 or 3 hours, and in cases where more determinative effects are demanded at once, from 60 to 120 grains at once. As a rule it is better to prescribe moderate and frequently-repeated doses rather than one large dose. The best mode of its administration is in distilled water, being well diluted, 1 part of the hydrate to 50 of water. When the dose is large, its bitter, pungent taste may be corrected by the addition of some syrup, tincture of orange, or by giving it in mucilage. There is some evidence of cumulative effects having been produced by chloral. In painful states, morphine, when not otherwise contraindicated, is often administered in conjunction with chloral hydrate. Alkaline additions to it must be avoided, and the chemical constituents of the food taken before or after its administration should be taken into consideration. It may be given in some aromatized syrup, to conceal its taste. When used in enema, the saturated solution should be mixed with some mucilaginous, albuminous, or oleaginous fluid. Chloral hydrate has been incorporated in suppositories, and Trelat proposed a mixture of morphine and chloral for producing incomplete anæsthesia for *minor operations*.

Specific Indications and Uses.—Sleeplessness, from cerebral hyperemia; pain, with cerebral hyperemia; pulse soft and temperature normal or somewhat increased; delirium tremens, with great cerebral excitation, dry, hot skin, dry tongue, elevated temperature, and flushed face; surgical fever, with elevated temperature, patient excited and delirious; spasms, when not associated with debility or depression; irritable dyspepsia (1 grain with berberine); nausea, retching, and vomiting, when dependent upon cerebral hyperemia; strychnine poisoning. Contraindicated by debility, depression, and organic heart and lung affections.

Related Drugs and Derivatives.—**CHLORAL ALCOHOLATE.** When chloral is mixed with one equivalent of alcohol, white crystals of chloral alcoholate are formed, resembling in appearance hydrate of chloral. They differ, however, in therapeutical action, and in being freely soluble in cold chloroform, carbon disulphide, and turpentine, while less soluble in cold water than the hydrate. When warmed with sulphuric acid, a reddish-brown, or brown solution is formed, and with nitric acid, red vapors are evolved (Hoffman). Chloral alcoholate yields 50.8 per cent of chloroform. It is not used in medicine, unless as an adulterant of chloral hydrate, and is of interest simply from the relation it bears to this substance.

CHLORAL-AMMONIUM ($\text{CCl}_3\text{CH.OH.NH}_2$), *Trichloramidoethylic alcohol*, occurs in small, white needle crystals, soluble in water, in which solution it is liable to undergo decomposition. Alcohol also dissolves it. It is prepared by rapidly passing into a chloroform solution of anhydrous chloral a stream of dry ammonia gas. A crystalline product is deposited, from which the chloroform is decanted; the crystals placed between layers of bibulous paper, and pressed, are finally dried in *vacuo*. It is employed as a hypnotic and analgesic, being indicated in cases due to *nervous and painful disorders*, accompanied by *nervous insomnia*. The dose is from 15 to 30 grains.

CHLORAL CYANHYDRIN, *Chloral hydrocyanate*, *Chloral hydrocyanin*, *Chloral cyanhydrate* ($\text{CCl}_3\text{CHOHCN}$).—This substance is prepared by the interaction of chloral hydrate and anhydrous hydrocyanic acid at a high temperature. It may also be prepared from a solution of the acid. This salt forms white, rhombic, plate-like crystals, easily dissolving in water, ether, and alcohol. It fuses at 61°C . (141.8°F .), has the combined odor of its ingredients, and, when heated to between 215° and 220°C . (419° and 428°F .), boils, and at the same time more or less decomposition ensues. Alkalies decompose it, the result being hydrocyanic acid, formic acid, and chloroform. It keeps well in aqueous solution, and yields 15.5 per cent of hydrocyanic acid; 1.29 parts in 9 parts of distilled water has the strength (2 per cent) of the official hydrocyanic acid. This compound is recommended as a substitute for prussic acid.

HYFNAL, *Monochlorantipyrine*, or *Tri-chloraldehyd-phenyl-dimethylpyrazolon*.—This hypnotic is produced by the interaction of chloral hydrate and antipyrine. It occurs as transparent, odorless, tasteless, rhombic crystals, soluble in water. It fuses at 58° to 60°C . (136° to 140°F .). This drug is hypnotic, antispasmodic, and analgesic, and is employed in *painful conditions* to produce sleep as well as to give rest where sleep is disturbed by harassing cough. Its value as a remedial agent is still in dispute, some claiming it to be a safe remedy in every respect, while others declare it liable to produce serious depressant effects, while others regard it as possessing but feeble hypnotic powers. It was introduced, in 1885, by Dujardin-Beaumetz as a soporific. The dose ranges from 15 to 30 grains, in capsules.

CHLORALOSE.—This crystalline body is one of the newer additions to medicine and is prepared by the reaction of anhydrous chloral and glucose (dry) upon each other when equal quantities are heated together for 1 hour at the temperature of boiling water. When cool, the resulting mass is first treated with a small amount of water and then with boiling ether. The portions soluble in ether are separated from excess of chloral by several distillations with water, then the chloralose is allowed to crystallize. Hot water and alcohol dissolve it. It is almost insoluble in cold water, and has a bitter taste. Hanriot and C. Richet regard this agent as a better hypnotic than chloral, it having given good results as a producer of refreshing sleep after both chloral and morphine failed. Physiologically, it is said to excite the medulla, and to exert its hypnotic action on the brain proper. Chloralose has been used in *hysteria*, *chorea*, and *epilepsy*. Doses as large as 35 grains were administered by Dr. Féré (1893). The sleep so produced in some of the hysterical patients was stertorous, and urine was passed involuntarily while asleep, thus exhibiting its pronounced effect in suspending cerebral action. Others report very favorably concerning its action, though occasional cases occur where headache, faintness, nausea, vertigo, and cardiac irregularity resulted from comparatively small doses. It has cured *dyspepsia* in a neurasthenic subject, and has been given with success in *valvular heart disease* of chronic character, and in *neurasthenia*. In *paralysis agitans*, 10 grains produced a deep sleep, followed, however, by aggravation of the muscular tremor (Ségaré). It has neither a constipating nor irritating action on the digestive tract. The dose is from 3 to 10 grains, given preferably in capsule.

URALIUM, *Chloral-urethane*, *Ural* ($\text{C}_2\text{H}_5\text{Cl}_2\text{O}_2\text{N}$, or $\text{CCl}_2\text{CH.OH.NHCO}_2\text{C}_2\text{H}_5$).—If urethane be dissolved in fused chloral hydrate and strong hydrochloric acid added, an insoluble (in water) mass results in the course of a day. If strong sulphuric acid be now added to this mass and the whole washed in water, an oily fluid, which afterward crystallizes, is produced. This is uralium, and it has a melting point at 103°C . (217.4°F .). It refuses to dissolve in cold water, while boiling water decomposes it. Alcohol freely dissolves it, as does also ether, and from these solutions it may be precipitated again by water. This body is said to be superior to chloral in hypnotic action, and is administered in doses of about 15 to 40 grains. It probably possesses no advantage over other hypnotics, and its lack of solubility will militate against its general utility.

SOMNAL.—*Ethylated chloral-urethane* ($\text{C}_2\text{H}_5\text{Cl}_2\text{O}_2\text{N}$). This compound is the result of a combination of chloral, urethane, and alcohol. As employed, it is a clear liquid, colorless, and has a pungent, burning taste, recalling that of spirit of nitrous ether. The dose ranges from 15 to 30 drops in liquorice water, or in solution, in water, flavored with raspberry or other syrups. It is hypnotic, though regarded as feeble in its action, and dangerously depressant to the heart's action. Others claim that a rather prolonged sleep (6 to 8 hours) is induced, and is followed by no evil after-effects.

CHLORALAMIDE.—*Chloralum formamidatum*, *Chloral formamide*, *Chloralformamidum* ($\text{CCl}_3\text{CH.OH.CONH}_2$). This hypnotic results from the interaction of formamide and anhydrous chloral,

and is official in the *German Pharmacopœia*. It forms lustrous, white, slightly bitter crystals, devoid of odor. It is soluble in alcohol (1½ parts), and slowly so in cold water (20 parts). Diluted acids do not affect it, but alkalies and water above 60° C. (140° F.) decompose it, forming ammonium formate and chloral hydrate. It should, on heating, volatilize without giving off inflammable fumes, and a 10 per cent solution in alcohol should not color litmus paper red, nor be immediately affected by solution of silver nitrate. It fuses at 115° C. (239° F.). It should not be confused with the chloral-derivative known as *chloralimide* ($\text{CCl}_3\text{CHN}^+\text{H}$), which occurs in long, odorless, tasteless, and colorless, acicular crystals, and is produced by heating chloral-ammonium. The latter is a stable salt, dissolves in alcohol, chloroform, ether, and fixed oil, but is insoluble in water. It fuses at 166° C. (330.8° F.). It is seldom employed in medicine. Chloralimide is hypnotic, and has been successfully employed as such in the treatment of the *insane*, in cases where great excitement is absent. If this condition is present it fails to operate as well. The same is true of its action in *delirium tremens*. In *painful conditions*, where the pain is not too severe, it induces refreshing sleep. It has been employed for this purpose in *asthma*, *chorea*, *cardiac affections*, *spinal affections*, *rheumatism* (muscular), and *insomnia*, of old or young subjects. It is thought to have a better action in *insomnia* due to *heart troubles* than chloral and other hypnotics. Mucous tissues are not irritated by it, nor is digestion deranged. It acts quickly, in from 15 to 50 minutes, giving a prolonged sleep, not followed by unpleasant after-sensations. Chloralimide may be given in wine, or in diluted whiskey, or better still, in warm (not hot) water. The dose is from 20 to 40 grains.

CHLORAL-PHENOL.—*Carbolated chloral*, *Chloral-carbol*. Equal parts of carbolic acid and hydrate of chloral triturated together, produce this substance, which is a viscid, colorless liquid, volatilizing with an odor closely resembling that of chloral hydrate. To the taste it is sweet and caustic. It may be mixed with alcohol, chloroform, ether, carbon disulphide, and acetic acid. Albumen is coagulated by it in small amounts, but larger quantities redissolve it. At 20° C. (68° F.), its density is 1.289. It is a local irritant, and a topical anæsthetic. *Toothache* is said to be relieved when cotton saturated with it is placed in the dental cavity. The cotton from the cotton-wood tree (*Populus canadensis*, Michaux), impregnated with it is preferred by Garrison (1881). The cotton so treated is known as *chloro-carbolated cotton*.

CHLORAL-MENTHOL.—*Mentholated chloral*. When equal amounts of menthöl and chloral are rubbed together and heated carefully by means of a water-bath, a colorless, oily liquid having the odor of peppermint and warm to the taste, results. It dissolves with freedom in alcohol, benzine, and chloroform, and is employed for its local anæsthetic and counter-irritant action, cases of facial, as well as other *neuralgias* having been relieved by it. It has a density of 1.1984.

CHLORAL CAMPHORATUM (N. F.).—*Camphorated chloral*, *Chloral et camphora*, *Chloral and camphor*. *Formulary number*, 23: "Chloral, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; camphor, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]. Mix them by agitation in a bottle, or by trituration in a warm mortar, until they are liquefied and combined"—(*Nat. Form.*). This preparation is employed as a counter-irritant and topical anæsthetic, particularly in *neuralgias*.

CHLORAL CARBAMIDE.—Mix in a porcelain mortar urea (carbamide) 60 parts, and trichloraldehyde hydrate 165.5 parts. A liquid will result which should then be dissolved in three times its bulk of water at 60° C. Upon cooling the solution a crystalline mass of chloral carbamide is deposited. This body, which Kobert has shown to act like chloral, but much slower, is easily soluble in cold, but less easily in warm alcohol. Warm water readily effects its solution.

CHLORALOXIMES.—A series of compounds recently introduced, which are not readily dissolved by water, but are soluble in ether and alcohol. Hot water has a tendency to decompose them, chloral hydrate being reformed. In the system they are said to split up into chloral hydrate and their particular oximes. The names and fusing points of some of these chloraloximes are as follows: *Chloral benzaldoxime*, 62° C. (143.6° F.); *chloralacetaldoxime*, 64° C. (147.2° F.); *chloralacetalaldoxime*, 74° C. (165.2° F.); *chloralcamphoroxime*, 98° C. (204.8° F.); *chloral-nitroso-beta naphtol*, 100° C. (212° F.).

CHLORAL BUTYLICUM.—BUTYL-CHLORAL HYDRATE.

FORMULA: $\text{C}_4\text{H}_9\text{Cl}_3\text{O}_2\text{H}_2\text{O}$. MOLECULAR WEIGHT: 192.91.

SYNONYMS: *Butyl-chloral hydras* (Br.), *Hydrate of butyl-chloral*, erroneously called *Croton-chloral hydrate*.

Preparation and History.—This body is produced by the action of chlorine gas upon acetic aldehyde in the cold, and subjecting the resulting product to fractional distillation. The fraction boiling between the constant limits 163° and 165° C. (325.4° and 329° F.), contains the practically pure butylchloral. By dissolving this in water the hydrate is produced, and may be obtained by crystallization. This body was accidentally discovered by Krämer and Pinner, in 1870, while examining the by-products of Schering's chloral works. At that time they regarded it as *croton-chloral* ($\text{C}_4\text{H}_5\text{Cl}_3\text{O}$), an unsaturated compound, but in 1875 they found it to be *trichlorobutyl-aldehyde*, having the graphic formula: $\text{CH}_2\text{CHCl}.\text{CCl}_2\text{CHO}$.

Description.—The hydrate occurs in scaly crystals, fusing at 77.8° C. (172° F.), the resulting transparent fluid congealing at 71.1° C. (160° F.). It is soluble in

hot water, alcohol, ether, and glycerin, more sparingly soluble in cold water (1 in 50), and practically not at all soluble in chloroform. Its taste is warm and bitterish. It vaporizes with the steam of water at 100°C (212°F). Its aqueous solution should be neutral or but faintly acid to test paper. Decomposition gradually ensues in its solution, and in such a state it can not long be kept. Caustic alkalis (soda, potash, etc.), convert it into formate and chloride of the base employed, and bichlorallylene ($\text{C}_2\text{H}_2\text{Cl}_2$), but chloroform is not produced under such treatment, a fact to be anticipated from the graphic formula above given.

Action, Medical Uses, and Dosage.—This agent was introduced in 1870, by Liebreich, as a remedy for *trigeminal neuralgia*. Within a few minutes after the ingestion of from 10 to 30 grains of this salt, a heaviness and mental confusion, and dulling of the senses take place. Sensibility of the skin, first of the face, and then of the limbs, is impaired, and motion is more or less impeded, muscular tone being peculiarly conserved, so that persons impressed with it will remain in deep sleep sitting upright in their chairs. Within a half-hour after taking the above doses a deep and peaceful slumber supervenes without affecting the circulation, temperature, or respiration. Slight head symptoms, quickly passing off, are experienced on waking. Large doses may induce emeto-catharsis. Rather than narcotic, this agent is an anæsthetic, and is peculiarly effective in *neuralgia of the fifth nerve* and in *tic-douloureux*, and is not of much value in other neuralgic complaints. Anemic girls and women are most benefited by it. It is only palliative, and for this purpose is likewise beneficial in *dysmenorrhœa* and in *nervous headache*, provided there is no depression of the heart, no gastro-intestinal irritation, nor a hyperemic state of the brain, which are contraindications to its use. It has been used in *insomnia*, particularly of *phthisis* and *heart affections*, when chloral was inadmissible, or when the required dose of the latter was too large. It affects females more readily than males, and the ordinary dose for neuralgic affections is from 3 to 15 grains. Larger doses are not safe. It may be administered in syrup of licorice, glycerin, or syrup of peppermint. It is best given in successive small doses until anæsthesia is produced, stopping short of its hypnotic action. For its hypnotic effects it is given at bedtime, in doses ranging from 15 to 45 grains. The patient's condition, however, must be taken into consideration for much harm may come from such doses. Electricity, artificial respiration, and stimulants, applied to the extremities, are the means resorted to when over-doses have been swallowed.

CHLOROFORMUM (U. S. P.)—CHLOROFORM.

FORMULA: CHCl_3 . **MOLECULAR WEIGHT:** 119.08.

SYNONYM: *Chloroformum purificatum* (Pharm., 1880).

"A liquid consisting of 99 to 99.4 per cent, by weight, of absolute chloroform, and 1 to 0.6 per cent of alcohol. It should be kept in dark, amber-colored, glass-stoppered bottles, in a cool and dark place"—(U. S. P.).

History and Preparation.—The first discovery of chloroform was in 1831, by Mr. Samuel Guthrie, a chemist residing in Sackett's Harbor, N. Y.; subsequently, in 1832, Soubeiran, of France, and Liebig, of Germany, prepared it; neither of these gentlemen being aware of the other's discovery. Chloroform is yielded by a variety of processes. It is formed by the action of chlorinated lime upon alcohol, acetone, wood alcohol, and other organic substances. It is also produced by the action of chlorine upon marsh gas (methane, CH_4), and on methyl chloride (see *Amer. Jour. Pharm.*, 1881, p. 188); by the decomposition of sodium trichloracetate (CCl_3COONa) with caustic soda, whereby sodium carbonate is formed as a by-product; and by the action of caustic soda upon chloral or chloral hydrate, sodium formate then resulting as a by-product (see *Chloral*). Until about 1882, the bulk of the chloroform of commerce was prepared by the action of chlorinated lime upon alcohol, whereby chloral is most likely formed as an intermediary product. In 1882, however, great improvements in the manufacture of acetone by the dry distillation of acetate of lime (see *Acidum Aceticum*) resulting in the cheapening of that article, made it possible to utilize Liebig's old reaction, according to which chloroform is made by distillation of acetone with chlorinated lime. The bulk of chloroform of the market is now obtained in this manner.

The yield of chloroform from acetone is considerable—namely, as high as twice the weight of the acetone employed. For an interesting paper on this subject see Prof. S. P. Sadtler in *Amer. Jour. Pharm.*, 1889, p. 321, wherein is also given the following equation as most likely expressing the reaction involved, calcium acetate being among the by-products formed: $2C_2H_5O + 6CaOCl_2 = 2CHCl_3 + Ca(C_2H_3O_2)_2 + 2Ca(OH)_2 + 3CaCl_2$. In addition to the advantage of a higher yield, greater purity is also claimed for the chloroform obtained by this process. As pure chloroform is now largely manufactured in this country, no formula for its preparation is given in the *U. S. P.* For detailed directions according to the old process with alcohol, see the *British Pharmacopœia*, 1885.

As the chloroform of commerce is often produced more or less impure, the *U. S. P.* has given the following process for its purification: *Purification*.—"Chloroform which fails to respond to these tests (*U. S. P.* tests) should be purified by the following process: Chloroform, four hundred grammes (400 Gm.) [14 ozs. av., 48 grs.]; sulphuric acid, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; dried sodium carbonate, twenty grammes (20 Gm.) [309 grs.]; deodorized alcohol, four cubic centimeters (4 Cc.) [65 Ml.]. Add the sulphuric acid to the chloroform, contained in a glass-stoppered bottle, and shake them together occasionally during 24 hours, avoiding exposure to bright daylight. Separate the lighter chloroform layer, add to it the dried sodium carbonate, previously rendered anhydrous by heating it in a porcelain capsule on a sand-bath until it ceases to give off aqueous vapor, and shake them together frequently and thoroughly during half an hour. Then transfer the chloroform to a dry retort, add to it the alcohol, and distill, by means of a water-bath, at a temperature not exceeding 67.2° C. (153° F.), into a well-cooled, tared receiver, until the distillate measures two hundred and fifty-five cubic centimeters (255 Cc.) [8 fl. 3, 299 Ml.]"—(*U. S. P.*).

Recently a physical method of obtaining pure chloroform was proposed by Pictet. It consists in subjecting chloroform to refrigeration to -82° C. (-147.6° F.), when pure chloroform solidifies, and may afterwards be distilled at a reduced temperature and pressure. An interesting chemical method has also been proposed by Anschütz (see *Amer. Jour. Pharm.*, 1893), by which chloroform enters into a solid combination. It consists in the formation of salicylide-chloroform, by allowing salicylide (C_6H_4COO , an anhydride of salicylic acid), or ortho-homo-salicylide ($CH_3C_6H_3COO$) and chloroform to remain in contact for 24 hours, when a crystalline, almost insoluble, product results, containing about 33 per cent of chloroform. This compound may be kept unchanged for a long time in closed containers. Salicylide-chloroform easily decomposes when heat is applied, yielding chloroform, free from the ordinary impurities, as these do not form crystallizable bodies with the above-named substances. Repeated use may be made of the same salicylide and ortho-homo-salicylide for the purification of chloroform according to this process.

Description.—The *U. S. P.* demands chloroform to answer the following description: "A heavy, clear, colorless, mobile and diffusible liquid, of a characteristic, ethereal odor, and a burning, sweet taste. Specific gravity: not below 1.490 at 15° C. (59° F.), or 1.473 at 25° C. (77° F.). Soluble in about 200 times its volume of cold water, and, in all proportions, in alcohol, ether, benzol, benzin, and the fixed and volatile oils. Chloroform is volatile even at a low temperature, and boils at 60° to 61° C. (140° to 141.8° F.). It is not inflammable, but its heated vapor burns with a green flame"—(*U. S. P.*).

Chloroform, when absolutely pure, has a density of 1.499 (Hirsch), or 1.502 (Schacht and Biltz), at 15° C. (59° F.). In this state it is exceedingly liable to decomposition upon exposure to diffused daylight and in contact with the atmospheric oxygen. The addition of a small quantity of alcohol has been found necessary in order to preserve it. Schacht and Biltz (see *Amer. Jour. Pharm.*, 1893) have determined the following specific gravities for chloroform, containing varying small amounts of alcohol. Specific gravity at 15° C. (59° F.):

Pure chloroform.....	1.5020
" " with 0.25 per cent alcohol.....	1.4977
" " " 0.5 " "	1.4939
" " " 1.0 " "	1.4854
" " " 2.0 " "	1.4706

The same investigators have found that, as a general rule, 0.25 per cent alcohol will prevent recognizable decomposition for one month or longer; 0.5 per cent will preserve the chloroform for nearly one year; and 1 per cent for several years. Similar results have been arrived at by Squibb (1893). According to the investigations of D. Brown (*Amer. Jour. Pharm.*, 1893), decomposition is induced by atmospheric oxygen. Chloroform, kept in a Torricellian vacuum, was exposed for several months to direct sunlight, during many hours, without change. Another specimen of chloroform being kept in a bottle, hermetically sealed, after the air was expelled by allowing the chloroform to boil in the glass for several minutes, likewise kept unchanged for 4 months (106 hours' sunlight), while chloroform not preserved with such precaution, and contained in a glass-stoppered bottle, began to decompose in 5 days (12½ hours' sunshine).

In the first stage of the decomposition, oxygen acts upon chloroform, decomposing it into water, chlorine gas, and carbon oxychloride (*phosgene gas*), a gas of a suffocating, nauseous odor, having a much lower boiling point than chloroform—viz.: 8° C. (46.4° F.). The reaction takes place as follows: $4\text{CHCl}_3 + 3\text{O}_2 = 4\text{COCl}_2 + 2\text{H}_2\text{O} + 2\text{Cl}_2$. In the second stage, carbon oxychloride reacts with the water present, forming carbon dioxide and hydrochloric acid, as follows: $\text{COCl}_2 + \text{H}_2\text{O} = \text{CO}_2 + 2\text{HCl}$. This reaction applies only to chloroform free from alcohol. If the latter is present, chlorine, probably in its nascent state, acts upon it, whereby hydrochloric acid is formed. Thus, in the presence of alcohol, the formation of free chlorine may escape notice. Free chlorine will be recognized by its property of liberating iodine from iodide of potassium, or from zinc iodide starch paper. Carbon oxychloride is recognizable by its peculiar smell, which becomes especially noticeable after shaking the chloroformic liquid with mercury, which takes up the free chlorine (Schacht and Biltz). Another test, suggested by Prof. Ramsay, consists in the action of the gas upon barium hydrate (see *U. S. P. tests* below). The following equation represents the reaction: $\text{COCl}_2 + 2\text{Ba}(\text{OH})_2 = \text{BaCO}_3 + \text{BaCl}_2 + 2\text{H}_2\text{O}$.

It is stated by Boettger that fragments of caustic soda will preserve chloroform even in the presence of light, and will restore chloroform containing hydrochloric acid and chlorinous compounds as products of decomposition.

Chloroform is a powerful solvent, and is thus a most valuable auxiliary to the chemist, pharmacist, and manufacturer. It is preferable to ether in many instances on account of its non-inflammability. Still, the fact must be borne in mind that if the vapors of chloroform are mixed with vapor of alcohol or ether, they become readily inflammable. M. Lepage has recorded the qualitative solubilities of a number of substances, such as resins, oils, alkaloids, and chemicals, in chloroform (see *Amer. Jour. Pharm.*, 1852, p. 147). A table of solubilities of alkaloids and alkaloidal salts in chloroform has been compiled by Schlimpert (see *Amer. Jour. Pharm.*, 1860). Chloroform has also become of some importance as an antiseptic. The solution of chloroform in alcohol is precipitated by an excess of water. Potassium and caustic potash have no action upon pure chloroform. With an alcoholic solution of potassa, however, it is decomposed, slowly in the cold, but more rapidly when heated, potassium formate and potassium chloride resulting. Chloroform is also used in the carbylamine test of Hofmann for aniline (see *Anilina*).

Impurities and Tests.—Pure chloroform, not containing *ethylidene chloride* (CH_3CHCl_2) and other chlorinated ethyl and amyl compounds, remains unaffected in color when shaken with pure concentrated sulphuric acid. According to Dr. Gregory, these chlorinated pyrogenous oils are the most pernicious foreign matters in chloroform, as they occasion, even when slightly inhaled, pain in the head, unpleasant nausea, etc. To detect these, he directs the addition of 2 or 3 ounces of the chloroform to an equal volume of concentrated and chemically pure sulphuric acid. If the chloroform be pure, the mixture will not be colored, but if these oils be present, the acid will be colored dark-brownish yellow, owing to the quantity of these foreign substances contained in the chloroform.

In testing the purity of chloroform, especial notice must be taken of its specific gravity; if less than 1.49, it contains a mixture of lighter fluids (alcohol, ether, or aldehyde), and, in this case, the volume of such a mixture sensibly diminishes when shaken with twice its bulk of pure water. The presence of alcohol in chloroform may be recognized by various tests—*e. g.*, the iodoform test, *i. e.*,

abstracting the alcohol by shaking with water and warming the solution with sodium carbonate and a crystal of pure iodine; if alcohol is present, the smell of iodoform becomes manifest. M. Roussin's test (referred to in the *French Codex*) is said to be extremely delicate, and consists in introducing several grammes of chloroform into a tube or stoppered bottle, then adding a few centigrammes of *nitroso-sulphide of iron*, shaking the mixture, and allowing it to settle. If the chloroform is pure, it remains clear as water; but if it contains alcohol, it assumes a brown tint, more or less deep, according to the proportion present. This reagent will also detect the presence of ether, aldehyde, and methylic and amylic alcohol, it being very soluble in all these compounds. The nitroso-sulphide of iron is procured by mixing a solution of nitrate of potassium with sulphide of ammonium, then, while the mixture is being agitated, dropping in a solution of ferrous sulphate. The whole is boiled, evaporated to dryness, treated with alcoholized ether, filtered, and the solution crystallized.

M. M. Béhal and François have recently elaborated a new method to determine the amount of alcohol present in chloroform. It consists in abstracting the alcohol by means of strong sulphuric acid, distilling the ethylsulphuric acid thus formed with water, and oxidizing to acetic acid the alcohol thus regenerated by means of potassium bichromate and sulphuric acid of known strength, according to the method of Nicloux (*Pharm. Centralt.*, 1897, p. 647).

The U. S. P. tests are the following: "If 20 Cc. of chloroform be poured upon a clean, odorless filter laid flat upon a warmed porcelain or glass plate, and the plate be rocked from side to side until the liquid is all evaporated, no foreign odor should become perceptible as the last portions disappear from the paper, and the paper should be left nearly odorless when compared with a new, odorless filter. If 10 Cc. of chloroform be well shaken with 20 Cc. of distilled water, and the liquid be allowed to separate completely, the water should be neutral to litmus paper, and should not be affected by silver nitrate T.S. (absence of chlorides), or potassium iodide T.S. (absence of free chlorine). If to about 5 Cc. of chloroform, contained in a dry test-tube of the capacity of about 10 Cc., about 4 Cc. of perfectly clear barium hydrate T.S. be added without agitation, and the test-tube be then corked and set aside in a dark place for 6 hours, no film should be visible at the line of contact of the two liquids (absence of products of decomposition in chloroform which may be otherwise pure). If 40 Cc. of chloroform be shaken with 4 Cc. of colorless, concentrated sulphuric acid in a 50 Cc. glass-stoppered cylinder during 20 minutes, and the liquids be then allowed to separate completely so that both are transparent, the chloroform should remain colorless, and the acid should appear colorless, or very nearly colorless, when seen in a stratum of not less than about 15 Mm. in thickness (absence of impurities decomposable by sulphuric acid). If 2 Cc. of the sulphuric acid, separated from the chloroform, be diluted with 5 Cc. of distilled water, the liquid should be colorless and clear, and, while hot from the mixing, should be odorless, or give but a faint vinous or ethereal odor (absence of odorous decomposition products). When further diluted with 10 Cc. of distilled water, it should remain clear, and should not be affected by silver nitrate T.S. (absence of chlorinated compounds). If 10 Cc. of the chloroform, separated from the acid, be well shaken with 20 Cc. of distilled water, and the liquid be allowed to separate completely, the watery portion should not be affected by silver nitrate T.S. (absence of chlorinated compounds)"—(U. S. P.).

Action and Toxicology.—I. INTERNALLY AND SUBCUTANEOUSLY. Chloroform applied to the skin reddens the part, and if evaporation be prevented, vesication is apt to result. Injected subcutaneously in small amounts (10 to 20 minims) it causes some pain at first, followed by a benumbing sensation, which is succeeded by complete anesthesia of the part, the tissue around the puncture becoming first puffy and then indurated, the induration persisting for many days. Taken internally, it imparts a sweetish, hot, and pungent taste, and if undiluted, may occasion severe irritation or inflammation of the mucous tissues. Hence it is customary to administer it in emulsion or as chloroform water. Heat and inflammation, followed by œdema of the larynx may occur if the concentrated vapor be inhaled during the act of swallowing the drug. In the stomach warmth is first experienced, followed by a cold sensation, and if the drug is not well diluted,

a severe gastritis may ensue. Effects not unlike those after the ingestion of alcohol or ether, follow when chloroform is taken in moderate amounts into the stomach—an increased circulation, fullness of the head, giddiness, mental confusion, and brief cerebral excitement or inebriation, succeeded by a soporific state. About 1 drachm subcutaneously, or 1 or 2-drachm doses by mouth, occasion a soporific state, which obtains very slowly, but is singularly prolonged, the drug presumably being very gradually absorbed into the blood. Such a sleep is not accompanied by anæsthesia, for the patient may be very easily aroused, and will again lapse off into sleep. The pulse is slightly slowed, while a reduction in temperature to the extent of 1° or 2° F. is generally effected. A dose of $\frac{1}{4}$ fluid ounce has occasioned alarming symptoms, among which are convulsions, trismus, partial pupillary dilatation, insensibility, retarded and stertorous breathing, frothing at the mouth, livid countenance, bloody stools, and feeble or irregular pulse. Blood may be ejected from the stomach also. Taken in lethal doses, profound stupor, insensibility, and death result. Death results from cardiac paralysis or from asphyxia, or from these and inflammation of the stomach combined. Under chloroform poisoning the pupils may either be contracted or dilated. Usually vomiting occurs, though after large doses no vomiting has taken place. A middle-aged, robust man, but an alcoholic inebriate, poisoned by the ingestion of $1\frac{1}{2}$ fluid ounces of chloroform, was aroused in 10 hours by the subcutaneous use of two large doses of strychnine ($\frac{1}{16}$ grain, followed in half an hour by $\frac{1}{8}$ grain). Severe gastro-intestinal, hepatic, and renal symptoms followed, the intellect remained clear, and the temperature unaffected, but death occurred in 67 hours from combined cardiac paralysis and pulmonary œdema (Taylor, *Med. Juris.*). The smallest fatal dose recorded was “a drachm or two,” which killed a boy of 4 years in 8 hours; 6 to 7 drachms is the smallest fatal dose in an adult. A fluid ounce has frequently killed, and the time required to produce death generally ranges from 1 hour to 8 days (Taylor, *Med. Juris.*).

The post-mortem appearances are congestion and inflammation—congestion of the brain and pulmonic structures, and congestion, inflammation, and ulceration of the gastric portion of the gastro-intestinal tract—the intestinal portion usually presenting nothing marked except some congestion and the odor of the drug. The bronchiæ are bathed with sanguineous mucus or muco-pus. Coagulation of the blood is prevented, that liquid being found unusually fluid in the vessels. The post-mortem appearances are not, as a rule, constant. Poisoning by swallowing chloroform must be met by emetics, the stomach-pump, or siphon; the further treatment is that of narcosis by inhalation. On account of its burning taste and pungency, it is rarely selected for suicidal purposes.

II. INHALATION AND ANÆSTHESIA.—The effects usually occasioned by anæsthetic doses of chloroform are, whizzing and pulsation in the head, a change in the apparent color of objects, pleasurable ideas and visions, loss of consciousness, incoherent talking or muttering, and sometimes loud or noisy respiration, muscular relaxation, and complete insensibility to pain, from whatever cause. A minute or two generally suffices to occasion anæsthesia, which will last for several minutes, but may be continued for an indefinite period, by carefully repeating the inhalation at certain intervals of time, as its influence is observed to be decreasing. Sometimes, from the coughing produced, or other circumstances, it may require a long time before its anæsthetic effect is induced, but which may be obviated by holding it, at first, at a little distance from the nostrils, that it may be mixed with atmospheric air, and then gradually approaching it to them. Its anæsthetic influence is succeeded by somnolence, or a calm slumber, and usually there is no remembrance of incidents which happen during the anæsthesia.

The full anæsthetic effects of chloroform are always attended with great hazard; it has been ascertained that it may be administered to an extent sufficient to produce torpor of the nerves of sensation without completely destroying consciousness, so that, in some cases, it may be unnecessary to risk the production of an entire suspension of the mental powers. Generally, however, it is unsafe to operate until complete unconsciousness has been effected, a majority of the fatal accidents from chloroform inhalation having been observed in minor operations where incomplete anæsthetization had been practiced. It is probable that the fatalities attending the extraction of teeth, etc., are in part due to the fact that

the drug was inhaled in the sitting posture; and that many deaths from chloroform have been hastened by fear. In inhaling chloroform, the article should be pure, as the presence of pyrogenous oils occasion vomiting; this effect is also apt to occur if the chloroform be inhaled immediately after a full meal. About a fluid drachm is the quantity generally used at a time for inhalation, and this should be renewed every 3 or 4 minutes until the required effect takes place. The only apparatus needed to inhale chloroform is a handkerchief, closely, but not too tightly, rolled up, and held in the hand, having a concavity into which the chloroform is poured, and then placed near, but not immediately in contact with, the mouth and nose. A quantity of common air should always be allowed to enter the lungs with the chloroform vapor. *It is never safe to administer chloroform vapor in greater proportion than $3\frac{1}{2}$ per cent, the rest being atmospheric air.* It should be remembered that the vapor of chloroform is heavier than air, so that it should not be held too close to the nostrils, lest the air should be wholly replaced by it. As soon as the requisite amount of insensibility occurs, its inspiration should be discontinued, and only carefully repeated when there is too early a restoration to consciousness. Epileptics, those laboring under disease of the heart, those predisposed to apoplexy, or cerebral determinations, and persons who have recently lost much blood, should not be placed under the anæsthetic influence of chloroform. It should never be administered immediately after a hearty meal, as it may cause vomiting; and when the pulsations fall below 60, the inhalation should be stopped. Excitement, which often marks the first degree of insensibility, is a mark that the handkerchief should be removed and not kept on, as is generally practiced. Violent excitement, and the exclamation, "I am choking," should be followed by the immediate removal of the handkerchief. The patient should be in the recumbent position, the head slightly raised by a pillow, and he should be frequently asked, while he is being pinched, what is done to him; and when he begins to answer with ill humor, "you pinch me," he is on the point of losing sensation. As soon as he answers no more, sensation is abolished, the handkerchief should be immediately removed, and the operation at once commenced, without waiting for a complete resolution of the muscles (M. Baudens). Some, however, prefer to wait for muscular relaxation, stopping short of stertorous breathing.

Before beginning the administration of the anæsthetic, certain precautions should be taken. All the implements to be used in the operation should be concealed from the patient's view, and all the necessary implements and restoratives deemed necessary in case of an accident, should be at hand, and also out of the patient's sight. The patient's chest should be bared, his fears allayed, and his confidence gained by the necessary explanations. Care should be taken that the clothing does not in any way constrict the circulation, nor should the administration be commenced after a full meal, nor after a long fast. The recumbent position must be maintained always. The administrator should attend to the administration of the anæsthetic, and to that alone. No talking nor noises, as the rattling of instruments, should be allowed, and there should be an abundance of fresh air admitted into the operating room. If desired an ounce of brandy or whiskey may be administered previous to the administration of the anæsthetic, or a hypodermatic injection of morphine, as suggested by Bernard, may be administered. The latter is said to render the process of inhalation quieter, and to lessen, and in some cases prevent the stage of spasm and rigidity nearly always present in the strong and robust, while it is also believed to antagonize the paralytic action of the chloroform upon the heart and lungs, and to prevent the shock succeeding the chloroformization and the operation performed. To prevent irritation and subsequent swelling of the nostrils and lips, the parts should be anointed with oil or petrolatum previous to the administration of the anæsthetic. Certain organic changes should be taken into consideration. Anæsthesia should not be attempted in those suffering from fatty and other degenerate conditions of the heart; it is inadmissible in feeble and obstructed heart, though it has been safely given where only valvular lesions exist, without change in the heart-muscle or cardiac ganglia, with apparent safety. The same is true of phthisis (Bartholow). Organic lesions of the brain, as cerebral tumors or abscesses, tendency to apoplexy, epilepsy, and obstructive lesions of the kidneys, are also contraindications to its

anæsthetic employment. Beside the previous named conditions, anæsthesia is improper in aneurism, chlorosis, most cases of phthisis, chorea, and anemia. We should be cautious in using it, if indeed, we should use it at all, where the tonsils are markedly enlarged, or when the epiglottis is swollen, or cedema of the glottis is present. It is a dangerous procedure to produce anæsthesia in old toppers, a fatty heart generally being present; and the inhalation of chloroform is likewise inadvisable in delirium tremens.

Great care should be exercised in the administration of the anæsthetic. The pulse, and particularly the respiratory movements should be carefully and continuously noted. Sudden pallor of the countenance and sudden and complete dilatation of the pupils are signs of the gravest danger. Stertorous breathing is the danger signal of respiratory paralysis, and when it occurs the chest should be vigorously slapped, as taught by Prof. Howe, until respiratory movements become free again. Children bear chloroform anæsthesia better than adults; women better than men; feeble persons and those reduced by long sickness better than the robust and healthy. This latter statement is disputed by some. It seems, however, that anæsthesia for operations upon diseased parts is better borne than when employed after injuries. Probably the shock and the terror attending the latter have much to do with the untoward action of the anæsthetic.

Much discussion has been made as to the method in which chloroform produces death, the belief formerly prevailing that it was nearly always due to cardiac paralysis. The first (1889) and second (1890) Hyderabad Commissions combated this view of its action upon the heart, and claimed that the lungs were the organs mainly and primarily involved. The experiments of this body, however, were performed in India and upon dogs. European and American observers have vigorously combated this theory of primary respiratory paralysis, the majority of deaths in Europe and America resulting from cardiac paralysis. Again, it shows the futility of trying to infer the action of a drug upon man because of certain effects produced in the lower animals. Indeed, it is not uncommon for entirely different effects to be produced upon man and animals by the same drug. Prof. J. A. MacWilliam (*Brit. Med. Jour.*, 1890), has recently shown that chloroform directly affects the heart substance, and that death from cardiac failure is the rule, the mode of failure being due to a more or less sudden dilatation of both sides of the heart, with marked enfeeblement of that organ, the feeble state and distension of the heart, which is unable to propel the blood, explaining the failure of artificial respiration to revive the patient. He shows that respiration may continue for several minutes after the heart has ceased to beat. The ground occupied by Wood (1890), Laborde (1890), Reeve, Hare, Dunlop, and others, is probably nearest to a correct solution of the lethal action of the drug. According to these observers, death may take place either from primary cardiac or from primary pulmonary paralysis, either taking place independently of the other. Thus death may result either from asphyxia or syncope. Dr. Wood maintains that while ether more generally acts upon the respiratory, more strongly than upon the circulatory organs, it may occasionally also produce death by heart paralysis. The treatment for chloroform narcosis, then, includes methods for sustaining both the cardiac and respiratory functions.

When administering chloroform, the operator ought always to be provided with a bottle of strong aqua ammoniæ, and whenever unpleasant symptoms arise, the patient should be made to inhale it from another handkerchief imbued with it, in the same manner as named for chloroform, and be either restored to sensibility, or not, as the case may require.

If the accident be due to respiratory failure, artificial respiration should be resorted to, and strychnine injected, or nitrite of amyl or ammonia inhaled. In case the tongue should tend to fall back into the throat, it should be drawn forward out of the mouth. The body should be placed head downward (Nelaton's method) in cardiac failure, to allow the blood to pass freely to the brain, and atropine, strychnine, and, best of all digitalis, administered hypodermatically. The latter is probably the best agent that can be employed. The use of alcoholics is questionable, as small quantities do no good, while large amounts aid in embarrassing respiration. External heat should be applied and cold affusions avoided. Recently it has been shown that forcible and sudden dilatation of the anal sphincters will

relieve patients from chloroform narcosis. While this has been ridiculed, we have the testimony of competent observers that it is signally effectual, operating probably through shock to the sympathetic nervous system.

CHLOROFORM HABIT.—Chloroform continuously consumed for the purpose of producing inebriation, as it often is, is more pernicious in its effects and more intractable to treat than the opium habit. Enormous quantities, as much as a pound, have been consumed in a day, but life can not long resist such amounts. Occasionally only acute symptoms lasting a week or so, and characterized by hallucinations of sight and sound, noisy delirium and furious maniacal raving may be the effects. More often, however, a chronic form ensues, with mental irritability, melancholia, or hypochondriasis, delirium, and early decay of the intellectual powers. The worst phases of moral depravity may also be exhibited. Fortunately, this use of the drug soon destroys its victims.

Comparison of Ether and Chloroform.—Chloroform is now very largely used by inhalation as an anæsthetic agent, and from the small quantity required, the promptitude with which it influences the system, its rather pleasant action, its more agreeable and less persistent odor, its moderate price, and the facility with which it may be administered, many in this country prefer it to ether, notwithstanding its greater danger. On the continent it seems to be losing ground, ether being preferred. The fact that chloroform is a much more dangerous anæsthetic, producing fatal results about 4.5 times as often as ether, makes the latter the more desirable agent to use in all operations where it is desired to produce anæsthesia. The majority of surgeons, and many of those who use chloroform, admit the greater safety of ether. Dr. Thomas Jones, of St. George's Hospital, London, who, in the course of eleven years, had administered chloroform to over 6,000 individuals, declared that if he were unfortunate enough to have to be anæsthetized, nothing could induce him to take chloroform. In obstetrics, however, chloroform is remarkably free from dangerous results, much more so than in any other condition, and is always preferred to ether in obstetrical manipulations.

A comparative table will show the advantages of ether over chloroform, while it will be observed that if equally as free from danger as the former, the latter would, from its pleasanter and prompter effects, be far preferable to the former.

ETHER.

- Unpleasant odor.
- Unpleasant to inhale.
- Inflammable, and can not well be used around fire and lights.
- More irritant to the air passages.
- May be given more rapidly.
- Air should be excluded as much as possible while administering.
- Its vapor may be inhaled almost in full strength.
- Reduces temperature several degrees.
- More apt to occasion pugnacity, or lascivious or vulgar talk.
- Not contraindicated by mere feebleness of heart.
- More irritant to the kidneys and lungs.
- Action less prompt and more transient.
- Comparatively free from danger.
- Kills chiefly by respiratory paralysis; occasionally by heart failure.
- Danger easily detected by color of face and ears, and state of pulse in sufficient time to resort to artificial respiration, by which death may be averted.
- Death occurs in proportion of about 1 to 17,000.
- Claimed never to be dangerous when properly administered.
- Should always be preferred in long operations.
- Less used in obstetrics.

CHLOROFORM.

- Agreeable odor.
- Pleasant to inhale.
- Non-inflammable and safe around fire and lights.
- Less irritant to the air passages.
- Must be slowly administered.
- Air to the extent of at least 97½ per cent should be mixed with the anæsthetic vapor.
- Not more than 3¼ per cent with the inhaled air is safe.
- Practically no reduction of temperature.
- More apt to render the ideas and visions pleasurable, the incoherent talk being of a pleasant and not vulgar character.
- Not admissible in weak heart.
- Less irritant to the renal and pulmonary tissues.
- Effects more prompt and more prolonged.
- Always dangerous.
- Kills chiefly by cardiac paralysis; and quite often primarily by asphyxia.
- Danger signs, as of pulse, pallor, etc., exhibited as quickly as with ether, but too late to be of value if cardiac paralysis has occurred.
- Death occurs in proportion of about 1 to 4,000.
- Admitted to be dangerous, even by its advocates.
- Preponderance of opinion in favor of never using where ether may be employed.
- Preferable in obstetric manipulations.

Notwithstanding its dangerous character, Prof. A. J. Howe was a strong advocate of chloroform, and in his incomparable article on ANÆSTHESIA (*Art and Science of Surgery*, pp. 38 to 51), states: "I have administered chloroform over 5,000 times, and have been so fortunate as not to have a death occur from the anæsthetic." He states that he has always succeeded in resuscitating the patient in handling several cases in which startling symptoms were exhibited, by his method, now well known to Eclectic practitioners, viz.: "Turning the patient on his face and forcing a finger deep in the throat to remove collections of mucus or material that is vomited, may clear the way for respiration which must be kept up artificially. While the patient lies upon his abdomen, the chest is to be turned every few seconds from one side to the other, and heavy slaps are to be imparted to the thorax just below the scapulæ. Blowing in the mouth is then to be quickly performed, and the turning and slapping renewed. Every few minutes the finger is to be forced deep into the pharynx, and the tongue pulled forward as the digit is removed. Efforts of the nature above described are to be kept up until no hopes of resuscitation remain. The manipulation favors a return of the heart's action and respiratory changes. If the feeble vital spark can be kept unextinguished there is a possibility of resuscitation. I once worked over a child for an hour, and my labors were rewarded by complete recovery" (Howe's *Surgery*, p. 48-9).

To obviate the alarming effects of chloroform, Dr. Warren proposed a mixture containing 2 parts of anhydrous alcohol, and 1 part of pure chloroform. This mixture is considered less dangerous than chloroform and more pleasant than ether. The suggestion that either alcohol or ether, by their stimulating qualities, overcome the prostrating effects of the chloroform, when in combination with it is probably correct (see Warren, "*On the Effects of Chloroform and Chloric Ether*"). However, nearly all modifications, such as the A. C. E. mixture, etc., have now been largely discarded, either pure ether, or chloroform, being employed singly.

Medical Uses and Dosage.—I. INTERNALLY. Internally, chloroform is a stimulant, sedative, antispasmodic, and anæsthetic. It has been used successfully in *asthma*, *spasmodic cough*, *scarlatina*, *atonic quinsy* to relieve the pain, *hysteria*, and to allay the pain in *lead colic*, *biliary or renal colic*, *passage of renal calculi*, *gastralgia*, *gastric ulcer*, *atonic dyspepsia*, *cancer*, *neuralgic affections*, and to avert chills in *intermittents*. It may be administered in doses of from 30 to 80 drops in solution of gum Arabic, or in a mixture of water and yolk of egg, repeating the dose if required, every $\frac{1}{4}$ hour, hour, or 2 hours, until it has occasioned the desired influence. Spirit of chloroform is an eligible preparation. The solution of camphor in chloroform is an elegant form of administering that medicine. Dr. T. H. Buckler recommends chloroform in teaspoonful doses every hour during the pain, and 3 times a day subsequently, as a preferable solvent of cholesterin in *biliary calculi*; to be followed by the use of the hydrated succinate of iron, to check the further formation of these calculi. Whether it dissolves the calculus or not, it certainly relaxes the spasm of the tube through which it passes, thus effectually allaying the pain. *Nausea and vomiting* where no inflammation is present, as of *sick headache*, *sea sickness*, *pregnancy*, etc., may often be relieved by giving from 2 to 5 drops of chloroform on sugar. Added to cough mixtures it aids in controlling *nervous cough*. Internally, a full dose administered just before the chill, may cut short a paroxysm of *intermittent fever*, and a few drops of chloroform, or better of chlorodyne, frequently arrests the symptoms of *Asiatic cholera*. While inhalations of chloroform are inadmissible in old toppers and in *delirium tremens* its internal use is valuable where marked depression is present. R Chloroform, fl̄j; diluted alcohol, fl̄ʒiij; tinct. capsicum, fl̄ʒiij. Mix. Sig. Teaspoonful doses in water. From 10 to 15-drop doses of the same are useful in *flatulent colic* and *hiccough*.

EXTERNALLY.—Externally, it has been employed in several forms of disease, and has been beneficially used as a local application to *gangrenous* and *cancerous ulcerations*, *dry gangrene*, *ulcerations of the mouth and fauces*, and in *copious uterine secretions*. It allays pain, corrects putrescent odors, and hastens the sloughing process; 1 or 2 fluid drachms of chloroform added to a pint of water, will answer for these purposes (Tuson). When a sponge, moistened with it, is placed in proximity with the os uteri, it has relieved *painful menstruation* (Higginson); applied to the sacrum, it has relieved the same disorder, and has also proved serviceable

able when applied externally in *tic-douloureux*, *rheumatic affections of the eye*, *soreness of the spinal column*, and in *orchitis*. The vapor applied directly to the part will often relieve the pangs of *sciatica* and the suffering from *myalgia*, *lumbago*, and *nervous headache*. Where the area is small, as in the latter, a little chloroform may be poured into a watch-glass and the latter inverted upon the part, as the temple. Applied in this way, or upon a folded handkerchief, it is effectual in localized *neuralgias*, as of the face. The vapor should be kept in contact until the pain is relieved. Prof. Locke recommends (*Syllabus of Mat. Med.*) the following as an efficient and elegant liniment for the relief of pain: R Chloroform, flzvj; tinct. aconite, flzii; spirit of camphor, flzjss; glycerin, flzss. Mix. Sig. Rub on the painful part. Another excellent liniment is the following: R Chloroform, tinct. aconite, aa ʒj; soap liniment, ʒii. Mix. Sig. Apply on flannel and cover with oil silk. Thirty minims of chloroform, mixed with 5 drachms of lard, has been employed as an ointment in *cutaneous eruptions* of a papular character. When applied to the uninjured skin there is no necessity for diminishing the strength of chloroform; a piece of lint moistened with it may be applied to the part, and its volatilization may be retarded by covering this with several thicknesses of muslin, India-rubber cloth, etc. If the chloroform is rendered impure by the presence of anhydrous alcohol, it is thereby rendered caustic (*Mialhe*). In *earache*, from *acute catarrh of the middle ear*, the vapor may be cautiously passed into the external meatus by means of an insufflator; the escape should not be prevented, however, lest the part be blistered. Therefore it should not be introduced on cotton. In both *mastodynia* and *mammitis* its local action has given relief, and applied to the perineum in *labor*, it has controlled the severe pain and relaxed the rigidity of the parts. Applied to the epigastrium it has relieved cases of *cholera morbus*, and over the abdomen it has allayed painful affections and spasms of the viscera. *Rheumatic toothache* may be palliated at least by rubbing the gum with chloroform, while camphorated chloroform will often alleviate pain from *dental caries*, if applied to the cavity on cotton. Deep subcutaneous injections, first employed by Bartholow, have been used to give relief in *neuralgias*, particularly of the trifacial nerve. The injection should be deep, and near the sheath of the nerve trunks. Induration follows where the needle is introduced, and occasionally abscess. Injection into the gums is asserted to frequently cause gangrene. A pledget of cotton, moistened with pure chloroform, has been introduced into the external auditory canal for the relief of the *photophobia* accompanying *interstitial keratitis*. It acts by anæsthetizing the Gasserian ganglion (*Gutierrez-Ponce*). A chloroform liniment has been made of oil of almonds, 2 fluid ounces; chloroform, 2½ fluid drachms; mix accurately. Pieces of flannel are to be soaked with this liniment, and applied to the painful part in cases of *nervous headache*, *neuralgia*, *rheumatic*, *hepatic*, *nephritic*, *uterine* or *intestinal pains*, *lead-colic*, etc. By adding double the quantity of oil, it may be used for vaginal injections, which may be retained by a plug of cotton, in cases of *dysmenorrhœa*, *uterine neuralgia*, or other painful affections of the uterus, bladder, or rectum.

Gelatinized chloroform has been recommended as an application by friction, or on compresses, to cause insensibility of the skin; it may be prepared in a few minutes, by agitating together the white of an egg with four times its weight of chloroform, and then setting the bottle containing the mixture in water having a temperature of 60° C. (140° F.). A weaker preparation, requiring 3 or 4 hours for the gelatinous change to occur, is made by agitating, in the cold, equal parts of white of egg and chloroform. Fournie states that equal measures of chloroform and glacial acetic acid form a mixture, the vapor from which will produce complete anæsthesia of the skin in a very few minutes.

III. BY INHALATION.—Chloroform was in use as an internal remedy for years before it became known as an anæsthetic. It was, however, used by inhalation in a case of *pulmonic embarrassment* as early as 1832. At the instigation of Mr. Waldie, of Liverpool, who had experimented with it in 1838-9, it was adopted and used first as an anæsthetic in November, 1847, by Dr. Simpson, of Edinburgh, who had been looking for a substitute for ether.

Chloroform is used to produce *anæsthesia*, to *relax spasm*, and to *alleviate pain*. Certain *respiratory neuroses* are relieved by its inhalation. In the same manner it may be used to give relief in the various forms of *colic*—, *bilious*, *flatulent*, *renal*, etc.:

dysmenorrhœa, *neuralgia*, *tic-douloureux*, *cancer*, and other painful states. For these purposes full anæsthesia is never required. It may be used in excited states, as in *hysteria*, *puerperal mania* (when not due to cerebral hemorrhage), *chronic insanity*, and *maniacal excitement*, and is extremely valuable in many *spasmodic disorders* of the muscular and nervous systems, many of which are also painful. Thus it is one of the best agents in *hiccough*, *convulsive hysteria*, *chorea*, *tetanus*, *hydrophobia*, and other *convulsive disorders*. In *asthma*, though it may not cure, it is unfailing as a palliative. It loses its power, however, after many repetitions of its use. It relieves severe *whooping-cough* and *convulsions* arising from cough. In *laryngismus stridulus* its effects are prompt. In *infantile convulsions* it is certainly one of the best agents to overcome the spasm, so that indicated drugs may be given to avert a return of the convulsive attacks. During the passage of *gall stones* and *renal calculi*, it not only relieves pain, but relaxes the spasmodically contracted tubes, thus facilitating the passage of the offending body. It is by far the best agent to control *uremic spasms* or *convulsions* from the same cause following *scarlatina*, while it stands at the head of all agents to check *puerperal eclampsia*. Morphine should also be hypodermatically injected. By the use of chloroform time is gained in which to administer other and appropriate remedies. It should not be forgotten as an aid in *poisoning by strychnine*. When no organic disease of the heart exists, the inhalation of chloroform will relieve *angina pectoris*, but the condition of the heart should be carefully ascertained before risking the agent. Amyl nitrite, followed by lobelia, is preferable.

Chloroform is principally used in *surgery* and *midwifery*, as an anæsthetic, for the purpose of producing insensibility to, or relieving pain and facilitating labor. In the latter state, it seems to be far safer than in any other condition. When labor is normal, brief, and not very painful, its use should be avoided. If, however, the opposite be true, no agent will act more beneficially and none will be more greatly appreciated by the woman. In first labors it should be used with great care. It is seldom necessary to carry it to complete anæsthesia, in fact, it should seldom be carried beyond the stage of merely blunting sensibility. It mitigates the pains, though it does not interfere with the force and frequency of the contractions, when not pushed too far, while it promotes relaxation of rigid parts. Pushed too far it interferes with the contractions and favors hemorrhage. Its use favors the easy performance of the required *obstetric operations*, as *turning*, *applying forceps*, *changing positions*, *extracting retained placenta*, or other manipulations, unless the patient be enfeebled by hemorrhage. If the latter state be present, and the agent must be employed, it should not be used to complete unconsciousness. In turning, enough must be given to suspend uterine action, while in forceps delivery enough should be administered to quiet the patient, or if necessary, to accomplish complete relaxation of the muscles. In instrumental interference it tends to prevent shock. In *craniotomy*, *symphyseotomy*, or *Cæsarion section*, the woman should be fully under the influence of the vapor. In most cases of labor a few whiffs of chloroform are allowed by many practitioners just as the head is emerging from the vulvar aperture.

Chloroform is of great value in facilitating *diagnosis*, where a thorough examination is necessary. It prevents pain, thoroughly relaxes the parts, and does away with any objections that might otherwise be made by the patient. It is especially useful to aid in determining obscure *abdominal*, *genito-urinary*, *pelvic*, and *rectal disorders*, and in examining *fractures* and *dislocations*. It is likewise useful in detecting *feigned diseases*.

By far the greatest use of chloroform has been to render *surgical operations* painless. Either this agent or ether is employed in all great operations. It may be used in performing *amputations*, *extirpating tumors*, in the reduction of *herniæ*, *adjusting fractured bones*, *reducing dislocations* (almost absolutely necessary here, to overcome muscular resistance), to rend *adhesions*, overcome *muscle* or *tendon contractions*, in performing *orificial work*, to correct *deformities*, and in dressing painful *ulcers* and *wounds*. Not only does it relieve the pain, but it also removes the fear and anxiety of the patient, and overcomes that muscular tension or rigidity which would otherwise defeat the surgeon in accomplishing a perfect result.

Prof. A. J. Howe, M. D., states that he has for some years been in the habit of administering chloroform, by inhalation, to break the force of *chills*. If given

when a chill is coming on, a condition foreshadowed by gaping and other well-known signs, the influence of the anæsthetic will prevent the paroxysm. He does not pretend that it eradicates the poison which causes the chills, or in any way takes the place of quinine, but by preventing or breaking up a paroxysm, time is gained in which to get an action from antiperiodic remedies. Dr. O'Bryan recommends a mixture of 10 drops, each, of laudanum, tincture of aconite, and chloroform, as being almost a specific in *intermittents*. It may be given 3 times a day for 7 or 8 days, during the intermission, preceding its use by a purgative.

The dose of chloroform is from 2 minims to 2 drachms; spirit of chloroform, from 10 to 60 minims, well diluted; chloroform water, $\frac{1}{2}$ to 2 fluid ounces; emulsion of chloroform, 1 to 5 drachms. For anæsthesia, by inhalation, the amount will be indicated by the effects produced. Dr. Thos. Skinner, of Liverpool, recommended the following preparation for internal use: *Spiritus Formylæ Terechloridi* (commonly called chloric ether). Chloroform, 5 fluid drachms; alcohol, specific gravity 0.838 at 15.5° C. (60° F.), 1 pint. Mix. Dose, $\frac{1}{2}$ to 2 fluid drachms, in a sufficient quantity of water.

Specific Indications and Uses.—To produce anæsthesia for surgical purposes; to alleviate pain; to relax spasm and control convulsions; to dissolve biliary calculi (?); to check severe and protracted chills (gtt. x to xx.).

Related Products.—**CHLORODYNE.** An empirical preparation under the name of *Chlorodyne*, has been somewhat popular in the profession of England and this country, as a remedy in *Asiatic cholera*; it is said to possess anodyne, diaphoretic, antispasmodic, and astringent properties. It is very effectual in many painful states of the viscera, and is prompt in its effects in *menstrual colic*. From 5 to 10 drops every hour until relief is obtained, is effectual to allay the frequent and painful micturition of *chronic cystitis*. As there are on the market many preparations bearing the name *Chlorodyne*, and nearly all varying in their composition, their strength should always be ascertained before administering them. Several formulæ for the preparation of chlorodyne have been published, from which the following are selected: Agitate together sulphate of morphine, 64 grains; alcohol (95 per cent), 2 fluid ounces; and purified chloroform, 6 fluid ounces; then gradually add sulphuric acid q. s. to make the mixture clear upon agitation; add oleoresin of capsicum, 12 drops; extract of *cannabis indica*, 30 grains; and Scheele's hydrocyanic acid, 96 drops. This forms a clear, dark, green liquid, each teaspoonful of which contains 1 grain of sulphate of morphine, about $\frac{1}{2}$ grain of extract of *cannabis*, and 14 drops of prussic acid, equal to nearly 4 drops of U. S. P. acid. The dose is from 15 to 30 drops. This preparation is said to be preferred to the original one by Dr. J. Collis Brown. But it must be used with care, as it must be extremely poisonous (E. McInall, Jr., *Amer. Jour. Pharm.*, 1868, p. 209). A less dangerous preparation was proposed by Prof. E. S. Wayne, as follows: Aqueous extract of opium, 12 grains; extract of *hyoscyamus*, 8 grains; oil of pepper-mint, 5 minims; oil of capsicum, 1 minim; camphor, 10 grains; alcohol, 4 fluid drachms; glycerin, 2 fluid drachms; chloroform, 2 fluid drachms. Mix.

CHORAMYL.—Chloroform, 1 pound; amyl nitrite, 2 drachms. Mix (Sanford).

CHLOR-ANODYNE.—This pharmaceutical preparation was devised and introduced by Parke, Davis & Co., of Detroit, and as made by them enjoys an enviable reputation. The formula is published in their literature, and is freely given to whoever wishes to study either its composition or its therapeutical action.

LYCOPERDON.—The fumes from burning the common puff ball (*Lycoperdon Bovista*, Linné) are said to be anæsthetic, but not equal to ether or chloroform. It possesses a volatile narcotic principle, which is not taken up by alcohol, water, or strong alkaline solutions (see p. 364).

CHONDRUS (U. S. P.)—CHONDRUS.

Chondrus crispus, Stackhouse (*Sphærococcus crispus*, Agardh; *Fucus crispus*, Linné), and *Gigartina mamillosa*, J. Agardh (*Sphærococcus mamilloeus*, Agardh; *Mastocarpus mamilloeus*, Kützinger; *Chondrus mamilloeus*, Greville).

Class: Algæ.

COMMON NAMES: Irish moss, Carragheen, Carraghen, Carragaheen.

Botanical Source.—*Chondrus crispus*, Stackhouse. Irish moss, sometimes called carrageen, has a root-disk, throwing up tufts of many flat, nerveless, slender, cartilaginous fronds, from 2 to 12 inches in height, subcylindrical at the base, but immediately becoming flat, generally dilating from the base upward, until they become 3 or 4 lines wide, then dividing repeatedly and dichotomously, each division spreading and becoming narrower than the preceding one, and taking place at shorter and shorter intervals; the summits are bifid, the segments linear, wedge-shaped, varying greatly in length, rounded or acute, straight or curved,

often twisted in such a manner as to give the curled appearance denoted in the specific name. The fructification is roundish or roundish-oval, and subhemispherical. The capsules are imbedded in the disk of the frond, prominent on one side, producing a concavity on the other, containing a mass of minute, roundish, red seeds. The substance is cartilaginous, in some varieties approaching to horny, flexible, and tough. The color is a deep purple-brown, often tinged with a purplish-red, paler at the summit, becoming greenish, and at length white in decay (L.).

Gigartina mamillosa, J. Agardh. This plant differs chiefly from the preceding in the situation of its cystocarps (sporocarps or capsules), which, instead of being slightly raised and near the extremities of the segments, as in the foregoing species, are borne on short, tuberculated projections or stalks, scattered over the channeled thallus.

History.—These are very common European plants found along the sea-coasts, especially along the west shores of Ireland, where quantities of it are gathered. They also grow on the Atlantic shores of this country. Large quantities of Irish moss are annually collected on the Massachusetts coast. It is found attached by its disk to the rocks along the sea, where it is collected in the spring-time, washed, and spread on the sands some distance from the shore-line, and allowed to lie in the sun until it becomes well bleached and of translucent, horny texture, when it is ready for market. It was introduced into medicine in 1831, by Todhunter, of Dublin. *Carrageen* (more properly *carrageen*) signifies, in Irish, "moss of the rock" (*Pharmacographia*). It is used to some extent in the arts, as sizing for paper and cotton fabrics in calico printing, for filling mattresses, and in this country in making beer. Cattle are sometimes fed on it (*Pharmacographia*). When fresh its color is somewhat purple, but when cleansed, and dry, as met with in commerce, it is in long crispy pieces, yellowish, or dirty-white, nearly inodorous, and of a mucilaginous taste. It swells up in warm water, and almost entirely dissolves in boiling water, forming a jelly when cold.

Description.—"Yellowish or white, horny, translucent; many-times forked; when softened in water, cartilaginous; shape of the segments varying from wedge-shaped to linear; at the apex emarginate or 2-lobed. It has a slight sea-weed odor, and a mucilaginous, somewhat saline taste. One part of it boiled for 10 minutes with 30 parts of water yields a solution which gelatinizes on cooling, and is not colored blue by iodine T.S."—(*U. S. P.*)

Chemical Composition.—Irish moss contains oxalate of calcium, compounds of sulphur, iodine, chlorine, bromine, potassium, magnesium, and sodium, and a large portion (as high as 80 per cent), of pectin matter. Flückiger, however, failed to find sulphur in the mucilage. Though starch is not present, Flückiger has shown that if thin pieces of the moss be treated for one day with solution of caustic potash in alcohol, the cell-contents (not cell-walls), react with a dark-blue coloration with the iodide of potassium iodine solution (*Pharmacographia*). Pereira considered the pectin to be a peculiar modification of mucilage, and has called it *carrageenin*. Carrageenin may be known from gum by its watery solution not affording a precipitate on the addition of alcohol; from starch by its not assuming a blue color with tincture of iodine; from animal jelly, by tannin causing no precipitate; and from pectin by acetate of lead not throwing down anything, though mucic acid is formed by the action of nitric acid.

Action, Medical Uses, and Dosage.—A decoction of Irish moss, with water or milk, is very nutritious, and may be used as a demulcent in *chronic affections of the air passages, chronic diarrhoea and dysentery, scrofula, rickets, enlarged mesenteric glands, irritation of the bladder and kidneys*, etc. As a culinary article it may be employed in the preparation of jellies, white soup, blanc mange, etc. The decoction is prepared as follows: Macerate $\frac{1}{2}$ ounce of carrageen in cold or warm water, during 10 minutes; then boil in 3 pints of water, or milk if stronger nourishment is desired, for a quarter of an hour. Strain through linen. Sugar, lemon-juice, tincture of orange-peel, essence of lemon, or other aromatics, as cinnamon or nutmeg, may be employed as flavoring ingredients.

Related Species and Drugs.—Other species of algae are said to be collected with the true Irish moss, the *Gigartina acicularis*, Lamouroux, having small, cylindrical segments, and having been sold in France as carrageen (Dragendorff). Another species resembling carrageen is the *Gigartina pistillata*, Lamouroux.

CEYLON MOSS. *Fucus amylaceus*, *Jaffna moss*, *Edible moss*.—The *Spherooccus lichenoides*, Agardh. Irregularly dichotomous, cylindrical, terminating in filiform extremities, of a reddish color (fresh); whitish and brittle when dried. Mucilaginous to the taste, and possessing a faint odor of sea-weed. A delicate moss from 4 to 10 inches in length. Contains metarabin, gelose, paramylon, cellulose, gum, other carbohydrates, some soluble in boiling water, others in soda solution, ash, albuminoids, and a substance soluble in alcohol (H. G. Greenish, 1882). This moss is collected from the Indian Ocean (Ceylon coast), and is one of the algae consumed by the *Collalia esculenta* (*Hirundo esculenta*), and other species of swallow of the East Indies, and after having been changed in the bird's gizzard, is made to enter into the formation of their nests, which constitute the **EDIBLE BIRDS' NESTS** of the Chinese. Ceylon moss is used like Irish moss.

AGAR AGAR.—This term is applied to several edible sea-weeds of the East Indies, and some of these varieties, largely employed by the Chinese for sizing silks and preparing jellies, have received commercial names as follows: *Chinese* (or *Japanese*) *isinglass*, or *gelatin*, derived chiefly from *Gelidium corneum*, Lamarek; and from *Eucheuma spinosum*, Agardh; *Eucheuma gelatinz*, Agardh; *Gelidium cartilagineum*, Gaillard; *Spherooccus compressus*, Agardh; *Gloiopeltis tenax*, J. Agardh, and other algae. This variety occurs in strips about a foot long, or in slender pieces a couple of feet in length, and of a yellow-white color. The strips are employed in bacteriological investigations. It is employed for the same purpose as jellies prepared from animal tissues, and its chief gelatinizing agent is *gelose* (Payen), a substance having greater gelatinizing properties than *carrageenin*.

Celebes or *Mucassar agar agar*.—The salt-incrusted *Eucheuma spinosum*, Agardh, and *Eucheuma gelatinz*, Agardh, gathered in the straits between the Celebes Isles and Borneo, and occurring as a brown-white moss, with sharp projections on its segments. It contributes to the preparation of Chinese gelatin (see above).

CORSICAN MOSS or **HELMINTHOCORTON**.—A mixture of a number of sea-algae gathered in the Mediterranean, one species of which, at least, is the *Spherooccus Helminthocorton*, Agardh, (*Gigartina Helminthocorton*, Greville; *Fucus Helminthocorton*, Linné). The latter has a cartilaginous, terete, tufted, entangled frond, with setaceous branches, is somewhat dichotomous, and marked indistinctly with transverse streaks. The lower part is dirty-yellow; the branches more or less purple (L.). This is a marine plant, growing on the Mediterranean coast, and especially on the Island of Corsica. The plant is of a cartilaginous consistence, of a dull and reddish-brown color, has a bitter, salt, and nauseous taste, and its odor is rather pleasant. It is found in the form of thick tufts, composed of numerous filaments, united at the base in bundles intermingled together, and fastened to each other by small hooks, with which the stems are furnished. It is seldom employed in this country: The commercial article consists of some 20 or more species, and may be whitish, yellowish, or of a brownish color. It contains bromides, iodides, and other salts, mucilaginous, and gelatinous material. Water dissolves its active principles. It is anthelmintic. The influence exercised by this substance upon the economy is hardly appreciable—perhaps occasionally a slight irritation of the digestive canal—but it acts very powerfully on the *intestinal worms*, especially the lumbricoid. Dr. Johnson affirms that when thrown into the rectum, "it destroys any worms domiciliating there as effectually as choke-damps would destroy the life of a miner." The dose is from 10 to 60 grains, mixed with molasses, jelly, or syrup, or in infusion.

DULSE.—The *Halymenia palmatus*, Agardh, and *Halymenia edulis*, Agardh, of the Atlantic and Mediterranean shores. Iodine, bromine, and mannit were found in these algae, which appear in commerce as deep-purple mosses, but when growing they have a rich red hue.

GELOSINE.—A substance under this name was proposed as a basis for preparations for topical use (*Brit. Med. Jour.*, Vol. II, 1886). It is a dried, mucilaginous preparation, occurring in sheets or leaves nearly white in color, and is the product of a Japanese sea-weed. It dissolves in both water and alcohol, but gradually contracting, expels the water or any foreign substance it may contain.

CHRYSAROBINUM (U. S. P.)—CHRYSAROBIN.

A more or less impure neutral principle extracted from Goa powder, a substance deposited in the wood of *Andira Araroba*, Aguiar (*Nat. Ord.*—Leguminosæ). See also **ARAROA** and **ACIDUM CHRYSOPHANICUM**.

History.—This body is extracted from Goa powder by means of hot benzene. It is largely used in the preparation of chrysophanic acid, which it contains in greater or less quantities, and as a local remedy for parasitic skin diseases. Its composition is mainly $C_{20}H_{12}O_7$. It was differentiated from chrysophanic acid by Liebermann and Seidler, in 1878. This substance, at one time supposed to be chrysophanic acid, is a neutral principle. As a commercial article, it is more or less impure, and is so recognized by the *U. S. P.*, where its use is directed in the preparation of *Unguentum Chrysarobini*.

Description and Tests.—Chrysarobin is a permanent, pale-yellow, or orange-yellow, warty, micro-crystalline powder. It is without taste or odor, but is an irritant to the conjunctival and Schneiderian membranes. It is "very slightly

soluble in cold water, or alcohol; soluble, without leaving more than a small residue, in 150 parts of boiling alcohol; also soluble in 33 parts of boiling benzol, and in solutions of the alkalies. When heated to 151°C . (303.8°F .), it fuses, forming a dark, opaque mass; and, when ignited, it is partly sublimed, and finally consumed without leaving a residue"—(*U. S. P.*). It dissolves in sulphuric acid with a yellow color when pure (chrysophanic acid dissolves with red color in this acid). It is somewhat soluble in fusel oil, chloroform, and collodion, but nearly insoluble in ammonia and dilute potassium hydroxide solutions, and yields a brown mass when fused with caustic potash. Chrysophanic acid, on the other hand, dissolves with a red color in dilute solution of the potassium hydroxide; fusion with that agent produces a blue compound. If chrysarobin be dissolved in concentrated solution of caustic potash, a yellow color, accompanied by a marked greenish fluorescence results. In contact with air the solution, by oxidation, turns red and changes to chrysophanic acid. Chrysarobin was named by Attfield, who obtained it by treating Goa powder with boiling benzol. It acquires a deeper tint upon exposure to the atmosphere.

"When boiled with about 2000 parts of water (which produces only partial solution), the light, reddish-brown filtrate does not affect litmus paper, and is not altered by ferric chloride T.S. In concentrated sulphuric acid it is soluble with a deep-red color; on pouring this solution into water, the substance is again deposited unchanged. On adding 0.1 Gm. of chrysarobin to 10 Cc. of potassium or sodium hydrate T.S., in a test-tube, and shaking the latter, the solution, which is at first yellow, or yellowish-red, will gradually acquire a deep-red color"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—The action of this body in certain skin affections is said to be due to its strong reducing powers, its affinity for oxygen being great. It is losing ground as a remedy on account of the occasional recurrence in a more severe form of the maladies that it appears to cure, and also on account of its irritating and staining qualities. *Erythema*, with swelling and cuticular desquamation, with reddening of the conjunctiva, are the effects of its application to the face or scalp. Intensely painful inflammation may succeed, lasting several weeks, and associated with it may be recurrent crops of boils. It has recently been lauded as a remedy for *hemorrhoids*, when combined with belladonna and iodoform in ointment and suppository. Its uses in *skin affections* are precisely those mentioned under araroba and chrysophanic acid (which see). It should not, as formerly, be prescribed under the name *chrysophanic acid*. Taken internally chrysarobin provokes purgation which, though at first delayed, continues for several days without marked discomfort. Doses of about 5 grains (children) and 25 grains (adults) are likely to first cause emesis. If used internally the 1 x or 2 x trituration should be preferred. Locally, the best ointment for general use may be prepared by incorporating 10 to 20 grains of chrysarobin with 1 ounce of lanoline or lard.

Related Products.—**ANTHRAROBIN.** *Desoxylizarin* ($\text{C}_{14}\text{H}_{10}\text{O}_2$). *Anthroarobin.*—A reduction product of commercial alizarin, produced by means of nascent hydrogen. A yellowish or yellowish-white powder, readily dissolving in alcohol, cold alkaline solutions, and glycerin; sparingly dissolved by chloroform, ether, and benzol, and practically insoluble in water and acidulous solutions. With fatty bodies it mixes readily to produce ointments. In alkaline solutions it absorbs oxygen from the air, turning to green and blue in color, alizarin being reproduced. When ignited the residue should not amount to more than 2 per cent. It has been used as a substitute for chrysarobinum and pyrogallol, because it is more easily dissolved than the former, and lacks irritant properties. It is weaker in its action than chrysarobin, though its stain is more pronounced upon the skin and linen.

HYDROXYLAMINE HYDROCHLORIDE ($\text{NH}_2\text{OH}\cdot\text{HCl}$).—Hydroxylamine exists free, only in solution. The salt used is the hydrochloride, which forms in hygroscopic, colorless crystals, dissolving in 1 part of water, 1 part of glycerin, and in 15 parts of alcohol. Its solutions are acid in reaction. The salt must be kept in well-closed bottles. It is a strong reducing agent. On account of its non-staining qualities, it has been recommended to replace anthrarobin, chrysarobin and pyrogallol in the treatment of skin affections, particularly *scabies*, *lupus*, *herpes tonsurans*, *chronic psoriasis*, *parasitic syphilis*, etc. A solution (1 to 1000) in glycerin and alcohol (equal parts) is preferred, being applied with a brush to small areas at a time. Stronger solutions do much damage to the skin, and many denounce its use at all, stating it to be inferior to the other applications mentioned and to be liable to serious consequences, both to the skin and to the general system through absorption. Constitutionally it induces a lowered blood pressure and destroys the blood corpuscles, rendering the blood brown in color. It is also destructive to plant life.

CICHORIUM.—CHICORY.

The root of *Cichorium Intybus*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES: *Chicory*, *Succory*, *Wild succory*.

ILLUSTRATION: Johnson's *Med. Bot.*, Fig. 138.

Botanical Source.—Chicory is a perennial plant, having a spindle-shaped, fleshy, whitish, and milky root. The stem is solid, round, furrowed, hispid, very tough, growing 2 or 3 feet high. The radical leaves are spreading, above a spear long, numerous, runcinate, toothed, and roughish. The cauline leaves smaller, sessile, less lobed, the uppermost cordate, acuminate, and entire. The flowers are large, 1 or 2 inches in diameter, axillary, in pairs, sessile, placed rather remote on the long, rather naked branches, and of a beautiful bright-blue color. Corollas flat and 5-toothed; involucre roughish; anthers and stigma blue (L.—W.).

History.—Chicory is a native of Europe, but cultivated in this country, where it grows in grass-fields and along roadsides, bearing large, elegant blue flowers in July and August. The root is quite bitter, and imparts its virtues to water. The young leaves are used as a salad. The plant is extensively cultivated for its root, which is used as a substitute for coffee, or for adulterating it: it is dried, roasted, and ground. J. L. Lassaigne states that an infusion of pure coffee acquires a more or less intense green color, when some drops of a solution of persulphate of iron are added to it; while an infusion of chicory retains its brownish color, becoming more intense with a greenish tint. Mr. Horsley proposed bichromate of potassium as a test. It produces no coloration with an infusion of chicory, but gradually changes the weakest infusion of coffee to a deep porter-brown color. When the two infusions are mixed, boil the mixture with the bichromate, add a few grains of sulphate of copper, and again boil. A flocculent precipitate is formed, of a more or less deep sepia-brown color, the intensity of which varies with the quantity of coffee contained. It is sometimes used as an adulterant of dandelion root.

Chemical Composition.—Besides the usual vegetable constituents, this root consists of more than one-third *inulin* ($C_{12}H_{22}O_{10}$), a fine, white, tasteless, and odorless powder, obtained chiefly by expression of the grated roots of various composite plants (see *Inula*). A very pure and pleasantly aromatic alcohol may be obtained from chicory root after the inulin has been converted into sugar by means of the mineral acids. A bitter glucosid, having the formula $C_{22}H_{34}O_{13}$, was obtained in colorless crystals from the flowers by Nietzki, in 1876. Alcohol and hot water dissolve it freely, while it is not soluble in ether. Sugar, pectin, and a bitter principle, not yet isolated, also exist in the root. The leaves yield a bitter body, albuminoids, sugar, and salts.

Action, Medical Uses, and Dosage.—Tonic, diuretic, and laxative. The decoction, used freely, is said to have proved efficient in *jaundice*, *engorgement of the liver*, and other *chronic visceral diseases*, as well as in *cutaneous eruptions*, *gout*, *herpes fever*, etc. An ounce of the root to a pint of water forms a good decoction. It is used as an adulterant of coffee.

Related Species.—*Cichorium Endivia*, Linné. *Garden endive*, a native of the Mediterranean countries, is said, by some French physicians, to be a remedy for jaundice. It is also cultivated and eaten as a salad.

CIMICIFUGA (U. S. P.)—CIMICIFUGA.

"The rhizome and roots of *Cimicifuga racemosa* (Linné), Nuttall"—(U. S. P.).
Nat. Ord.—Ranunculaceæ.

COMMON NAMES: *Black snakeroot*, *Black cohosh*, *Rattleroot*, *Rattleweed*, *Squarroot*.
ILLUSTRATION: *Drugs and Med. of N. A.*, by J. U. and C. G. Lloyd, Pl. 21, Vol. 1.

Botanical Source.—This plant is a tall, leafy, perennial herb, having a large, knotty root, with long, slender fibers, and a simple, smooth, furrowed stem, from 3 to 9 feet high. The leaves are large, alternate, and ternately decompose. The leaflets ovate-oblong, incisely serrate, and opposite. The flowers are fetid, small, and borne in long, terminal, slender racemes. The sepals are 4 or 5 in number.

rounded, and white; petals from 4 to 6, small, not so long as the sepals, resembling abortive stamens, and apt to be overlooked. The stamens are very numerous and showy; the anthers introrse and white. The stigma sessile, and lateral; pistils oval, forming dry, dehiscent, ovate, follicular capsules; the seeds numerous, small, and compressed (W.—G.).

History.—The black cohosh is a plentiful and conspicuous plant, growing in fence corners, on side hills and in rich woods. It blooms from the latter part of June until August. It grows from the Indian Territory to the Atlantic coast, extending as far north as the great lakes, and nearly as far south as Florida. The center of distribution is in the Ohio Valley. The part used in medicine is the rhizome, gathered in the autumn and carefully dried in the shade. It has an unpleasant, faint, earthy odor. Boiling water takes up its properties only partially; alcohol or ether wholly. The seeds probably possess active properties. The resin is but little used at the present time except in pill form, in combination with other agents.

Cimicifuga has several common names, as *makeroot* and *rattleroot*, having been used to cure rattlesnake bites; *rattleweed*, from the fact that the seeds remaining in the pods through a part of the winter, rattle when blown by the winds; *squawroot*, a name more properly belonging to blue cohosh; and its pharmacopœial name, *black makeroot*. The name *macrotys*, adopted by some Eclectics, is an erroneous one, given by De Candolle, the celebrated French botanist. The proper word is *macrotyrs*, from two Greek words meaning a large bunch, referring to its large raceme of fruit. *Cimicifuga*, its present botanical name, is derived from *cimex* (bedbug), and *fugare* (to drive away), the European species having been used as a bug exterminator. The drug is best known to the members of our school as *MACROTYS*.

This interesting remedy was a decided favorite with the early Eclectic practitioners, and to this day holds a very prominent place among the remedies originally placed before the medical profession by our school. As early as 1785, Schoepf merely mentioned the plant, but its medical uses were first recorded by Barton, in 1801, who called it *squawroot*, and writes: "Our Indians set a high value on it." He describes its use in putrid sore throat, itch, and in diseases of women, and further adds that it was used in the treatment of murrain in cattle. Other investigators wrote concerning it from time to time, but to Prof. John King belongs the credit of placing it before the medical profession, and it was through his valuable writings that it became an established and valued remedy. Prof. King began the

use of *macrotys* in 1832, when but few physicians knew anything concerning it as a medicine. In 1835 he prepared the first resin of *cimicifuga*, often sold under the improper names of *cimicifugin*, *macrotyn*, or *macrotin*. In 1844 he called the attention of physicians to it, and again, in 1846, wrote of it in the *Western Medical Reformer*; though the remedy did not come into general use until about 1850. Finally, when the *Eclectic Dispensatory* appeared in 1852, Dr. King gave the remedy great prominence, and from that time on it has been used very extensively by the Eclectic physicians.

Description.—"The rhizome is of horizontal growth, hard, 5 Cm. (2 inches) or more long, about 25 Mm. (1 inch) thick, with numerous stout, upright or curved branches, terminated by a cup-shaped scar, and with numerous, wiry, brittle,

Fig. 71.

Branch of a raceme of *Cimicifuga racemosa*.

Fig. 72.

Fresh rhizome of *Cimicifuga racemosa*.

more long, about 25 Mm. (1 inch) thick, with numerous stout, upright or curved branches, terminated by a cup-shaped scar, and with numerous, wiry, brittle,

obtusely quadrangular roots, about 2 Mm. ($\frac{1}{4}$ inch) thick; the whole brownish-black, of a slight, but heavy odor, and of a bitter, acrid taste. The rhizome and branches have a smooth fracture, with a rather large pith, surrounded by numerous sublinear, whitish wood-rays, and a thin, firm bark. The roots break with a short fracture, have a thick bark, and contain a ligneous cord expanding into about 4 rays"—(*U. S. P.*).

Chemical Composition.—The root yields an impure mixture of resins, to which the names CIMICIFUGIN, MACROTIN, or MACROTYN, have been given. It may be readily prepared by precipitation of the alcoholic extract by the addition of water. Dr. G. W. Mears (*Phila. Monthly Jour. Med. and Surg.*, Sept., 1827) first examined the plant chemically, obtaining therefrom gum, resin, starch, gallic acid, tannin, extractive, and a bitter (acrid) substance, but failed to obtain an alkaloid, for which he searched (*D. & M. of N. A.*, Vol. I, p. 262).

In 1871, Mr. T. Elwood Conrad announced the discovery of a neutral, "crystallizable principle in black snakeroot." By a circuitous process he obtained "a crystalline substance of a light yellow color, not of a very regular or decided shape, but of a massy appearance, resembling almost exactly the crystals of sulphate of aluminum on a small scale." In its behavior and most of its physical properties it resembled the resin. Mr. L. F. Beach (1876) claims to have found the same body in cimicifugin. M. S. Falck (1884) obtained from the fresh juice a body similar to Conrad's, and suspected it to be of an alkaloidal character. Both Profs. F. H. Trimble and J. U. Lloyd, who examined the drug in all conditions, failed to obtain a proximate crystalline substance. The same negative results attended the investigation of Prof. R. R. Warder. Prof. Lloyd believes the product obtained by Conrad to have been merely purified resin—*i. e.*, the resin of cimicifuga (cimicifugin) purified from extraneous substances, and that the gentlemen, who supposed they had obtained a crystalline body, were mistaken as to its structure, or, if they obtained crystals, that they mistook a lead or aluminum salt for a product of cimicifuga. The fresh juice, from which Mr. Falck is said to have obtained crystals, is, according to Prof. Lloyd, composed chiefly of glucose, and has no resin, or but very little of it. According to the latter, the resins are the important constituents of the drug. (See *Drugs and Med. of N. A.*, by J. U. and C. G. Lloyd, Vol. I, p. 262).

Besides the above resinous body, black and green coloring matters, tannic acid, gallic acid, salts of iron, calcium, magnesium, and potassium were found in 1834 by J. H. Tilghman (*Jour. Phil. Col. Pharm.*, VI, p. 20). Mr. G. H. Davis has found the root to contain gum, albumen, extractive, starch, uncrystallizable sugar, tannic acid, gallic acid, resin soluble in alcohol or ether, resin soluble in alcohol and insoluble in ether, fatty matter, waxy matter, volatile oil having the peculiar odor of the root, green and brown coloring matters, lignin and salts of potassium, magnesium, calcium, iron, and silica (*Amer. Jour. Pharm.*, 1861, p. 391). Mr. E. C. Jones found the seeds of cimicifuga to contain gum, starch, fat, tannic acid, gallic acid, a resin soluble in alcohol or ether, a resin insoluble in alcohol, but soluble in ether, and salts of potassium and calcium (*Proc. Amer. Pharm. Assoc.*, 1865, p. 186).

Action, Medical Uses, and Dosage.—This is a very active, powerful, and useful remedy, and appears to fulfil a great number of indications. It possesses an undoubted influence over the nervous system. In small doses the appetite and digestion are improved, and larger amounts augment the secretions of the gastro-intestinal tract. Excretions from the skin and kidneys are increased by it, the peculiar earthy odor of the drug being imparted to the urine; the secretions of the bronchial mucous surfaces are also augmented under its administration. Upon the heart and circulatory system its effects have been compared to those of digitalis, though being much less pronounced. The heart-beat is slowed and given increased power by it, while arterial tension is elevated. In large doses its action on the nervous system is very decided, producing vertigo, impaired vision, dilatation of the pupils, nausea, vomiting, and a reduction of the circulation, but no alarming narcotic effects. Three drops of the saturated tincture given every hour, for 20 hours, have been known to produce symptoms in every way simulating those of delirium tremens. Green tea is said to counteract its narcotic influences.

Upon the reproductive organs it exerts a specific influence, promoting the menstrual discharge, and by its power of increasing contractility of the unstriped fibres of the uterus, it acts as an efficient parturient. The venereal propensity in man is said to be stimulated by cimicifuga.

Few of our remedies have acquired as great a reputation in the treatment of *rheumatism* and *neuralgia*. As early as 1844, in the *New York Philosophical Journal*, Dr. King recommended the use of a saturated tincture of cimicifuga in *acute rheumatism*, stating that the remedy would permanently cure the disease. Prof. King's own statement of his use of it is as follows: "The saturated tincture of this article was recommended by me in acute rheumatism, in the *New York Philosophical Journal*, as early as in the year 1844; to be given in doses of 10 drops every 2 hours, gradually increasing to 60 drops, or until its action on the brain is observed, which action must be kept up for several days; it almost always removes the disease permanently, especially if it is a first attack." The experiences of other physicians since that day give abundant evidence of the truth of his statement. Indeed, few cases of rheumatism, or conditions depending upon a rheumatic basis, will present, which will not be influenced for the better by macrotys. *Rheumatism of the heart, diaphragm, psoas muscles, "lumbago," "stiff neck,"* in fact all cases characterized by that kind of pain known as "rheumatic," dull, tensive, intermittent, as if dependent upon a contracted state of muscular fibre, soreness in muscular tissue, especially over the abdomen and in the extensor and flexor muscles of the extremities, all yield readily to it. If there be febrile and inflammatory conditions it should be associated with specific aconite, or specific veratrum; or possibly specific asclepias will be indicated. If the pain be greatly aggravated by motion, and especially if the serous tissues be involved, specific bryonia should be added to it. Should there be burning pain, aggravated by warmth of the bed, specific rhus. If effusion of serum into cellular structures be present, combine the macrotys with specific apocynum.

In *cardiac rheumatism* it should be given early and in quite full doses, withdrawing the remedy when the full and dull headache is produced by the drug. In this way confirmed rheumatism of that organ may often be averted. It is most useful in acute cases, being of value only to relieve the acute complications that may arise in chronic cardiac rheumatism.

Muscular pain of a rheumatoid character, when not amounting to a true rheumatic attack, and other *rheumatoid pains*, when acute and not of spinal origin, such as *gastralgia, enteralgia, tenesmic vesical pain, pleurodynia, pain in the mediastina, orbits or ears*, are relieved by cimicifuga. In *diseases of the ear* the drug is indicated when the condition is aggravated by rheumatic association, or in *neuralgia* of the parts with stiffness in the faucial and pharyngeal muscles. The dose should be about $\frac{1}{2}$ to $\frac{1}{4}$ drop of specific macrotys every 2 hours. In *eye strain*, giving rise to headache, and associated with a sensation of stiffness in the ocular muscles, or a bruised feeling in the muscles of the frontal region, the same sized doses will give marked benefit. In doses of 1 fluid drachm of the tincture, repeated every hour, it has effected thorough cures of *acute conjunctivitis*, without the aid of any local application. Cimicifuga is a remedy for *dyspeptic manifestations* when due to rheumatoid states of the gastro-intestinal tube, or when associated with rheumatism of other parts of the body. It should be remembered in those cases where there is a dull or aching pain and tendency to metastasis, made worse by taking food or drink, and when the walls of the stomach seem to be contracting upon a hard lump, the patient having a rheumatic tendency or history (Webster).

Macrotys plays a very important part in the therapeutics of gynecology. It is a remedy for *atony of the reproductive tract*. In the painful conditions incident to imperfect menstruation, its remedial action is fully displayed. By its special affinity for the female reproductive organs, it is an efficient agent for the restoration of *suppressed menses*. It is even a better remedy in that variety of *amenorrhœa* termed "*absentio mensium*." In *dysmenorrhœa* it is surpassed by no other drug, being of greatest utility in irritative and congestive conditions of the uterus and appendages, characterized by tensive, dragging pains, resembling the pains of rheumatism. If the patient be despondent and chilly, combine macrotys with specific pulsatilla, especially in anemic subjects. In the opposite condition associate it with gelsemium. It is a good remedy for the reflex "*side-aches*" of the

unmarried woman; also for *mastitis* and *mastodynia*. It should be remembered in *rheumatism of the uterus*, and in *uterine leucorrhœa*, with a flabby condition of the viscus, its effects are decided. When there is a disordered action or lack of functional power in the uterus, giving rise to *sterility*, *cimicifuga* often corrects the impaired condition and cures. *Reflex mammary pains* during gestation are met by it, and in rheumatic subjects it promptly relieves such ovarian troubles as *ovari-algia* and *neuralgia*, the pain being of an aching character. *Orchialgia* and *aching sensations of the prostate* are conditions calling for *macrotys*, and as a tonic it is not without good effects in *spermatorrhœa*.

Macrotys has proved a better agent in obstetrical practice than *ergot*. It produces natural intermittent uterine contractions, whereas *ergot* produces constant contractions, thereby endangering the life of the child, or rupture of the uterus. Where the pains are inefficient, feeble, or irregular, *macrotys* will stimulate to normal action. It is an excellent "*partus preparator*" if given for several weeks before confinement. It is a diagnostic agent to differentiate between *spurious* and *true labor pains*, the latter being increased, while the former are dissipated under its use. It is the best and safest agent known for the relief of *after-pains*, and is effectual in allaying the general excitement of the nervous system after labor.

Macrotys exerts a powerful influence over the nervous system, and has long been favorably known as a remedy for *chorea*. It may be used alone or with specific *valerian*, equal parts. It is particularly useful here when associated with *amenorrhœa*, or when the menstrual function fails to act for the first time. Its action is slow, but its effects are permanent. It has been used successfully as an antispasmodic in *hysteria*, *epilepsy* when due to menstrual failures, *asthma* and kindred affections, *periodical convulsions*, *nervous excitability*, *pertussis*, *delirium tremens*, and many other *spasmodic affections*.

For *headache*, whether congestive or from cold, *neuralgia*, *dysmenorrhœa*, or from *la grippe*, it is promptly curative. As a palliative agent in *phthisis pulmonalis*, good results are obtained, in that it lessens *cough*, soothes the pain, especially the "aching" under the scapulæ, lessens secretions and allays nervous irritability. *Fevers*, *intermittent* and *remittent*, have been benefited by it, well-marked antiperiodic and tonic virtues having been observed in the drug. For *rheumatic fever* we have no better agent, when combined with *aconite* or *veratrum*. In the cerebral complications of the *simple* and *eruptive fevers*, especially in children, its action is prompt and decisive. It uniformly lessens the force and frequency of the pulse, soothes pain, allays irritability, and lessens the disposition to cerebral irritation and congestion. In febrile diseases especially, it frequently produces *diaphoresis* and *diuresis*. In the *exanthemata*, it is a valuable agent, controlling pain, especially the terrible "boneaches" of *smallpox*, rendering the disease much milder. In *scarlatina* and *measles*, it relieves the headache and the backache preceding the eruptions. It is stated that it has been used in the South with some success as a prophylactic against *variola*. *Cimicifuga* exerts a tonic influence over both the serous and mucous tissues of the system, and will be found a superior remedy in the majority of chronic diseases of these parts. In all cases where acidity of the stomach is present, this should first be removed, or some mild alkaline preparation be administered in conjunction with the remedy, before any beneficial change will ensue. As a remedy for pain, *macrotys* is a very prompt agent, often relieving in a few hours, painful conditions that have existed for a long time.

The saturated tincture of the root is recommended as a valuable embrocation in all cases where a stimulant, tonic, anodyne, and alterative combined is required, as—in all cases of *inflammation of the nerves*, *tic-douloureux*, *periodic cephalic pain*, *inflammation of the spine*, *ovarian inflammation*, *spasms of the broad ligaments*, *rheumatism*, *crick in the back or side*, *inflammation of the eyes*, *old ulcers*, etc. If a more active preparation is desired, add tincture of grains of paradise in proper quantity, and if a more powerful anodyne be needed add tincture of sulphate of morphine. The specific *macrotys* will be preferable to the saturated tincture. The local use of the drug, however, is not extensive.

Cimicifugin, whose action differs somewhat from *macrotys*, was used by Prof. King in the treatment of "*chronic ovaritis*, *endometritis*, *amenorrhœa*, *dysmenorrhœa*, *menorrhagia*, *frigidity*, *sterility*, *threatened abortion*, *uterine subinvolution*, and to relieve severe after-pains."

Preparations of *cimicifuga*, to be of any medicinal value, must be prepared from recently dried roots. In *phthisis pulmonalis*, *cough*, *acute rheumatism*, *neuralgia*, *scrofula*, *phlegmasia dolens*, *amenorrhœa*, *dysmenorrhœa*, *leucorrhœa*, and other *uterine affections*, the alcoholic preparations, as the saturated tincture or the specific *macrotys* are the best modes of exhibition, and exert a therapeutic influence not to be obtained from the impure resin, termed *cimicifugin*.

As a *partus accelerator*, it may be substituted for, and should be preferred to, *ergot*; $\frac{1}{2}$ drachm of the powdered root may be given in warm water every 15 or 20 minutes, until the expulsive action of the uterus is induced, and which it seldom fails to bring on speedily and powerfully. The powder, however, is seldom now used, the specific *macrotys* in from 15 drops to $\frac{1}{2}$ fluid drachm being given in the same manner. In acute troubles, as *acute muscular rheumatism*, and in *false pains*, and as an *oxytocic*, Webster prefers the strong decoction of the recent root in tablespoonful doses. The fluid extract of black cohosh may be used in all cases where the article is indicated; its dose is from $\frac{1}{4}$ fluid drachm to 2 fluid drachms. The ordinary dose of *macrotys* for its specific effects is a teaspoonful of a mixture of from 10 drops to 1 drachm of specific *macrotys* in 4 ounces of water, the larger or smaller dose being determined by the condition of the patient.

Specific Indications and Uses.—Dr. Scudder gives as the specific indications for this drug: "Muscular pains; uterine pains, with tenderness; false pains; irregular pains; rheumatism of the uterus; dysmenorrhœa. As an antirheumatic, when the pulse is open, the pain paroxysmal, the skin not dry and constricted."

To these may be added a sense of soreness, with dragging pains in the hips and loins; rheumatoid muscular pain; rheumatoid dyspepsia; chorea, associated with "*absentio mensium*."

CINCHONA (U. S. P.)—CINCHONA.

The bark of several species of *Cinchona*.

Nat. Ord.—Rubiaceæ.

Botanical History and Source.—The tribe CINCHONÆ, of the natural order Rubiaceæ, includes the genera *Cinchona*, *Cascarilla* (with *Buena* and *Cosmibuena*), *Remijia*, *Macrocnemum*, *Ladenbergia*, and about 30 other nearly allied genera (see *Pharmacographia*). This tribe is comprised of those opposite-leaved shrubs or trees bearing a 2-celled, many-seeded, dry, capsular fruit, and having scale-like, deciduous stipules. The inflorescence is expanded or branched, and not capitate or contracted. The numerous seeds are small and bordered all around by a broad membranous wing, lacerated or toothed at the edge. The subtribe *Eucinchonæ* has valvate corollas in contradistinction to the subtribe *Hillieæ*, which has the corolla contorted; inflexed, or imbricated.

The genus *Cinchona* is finally distinguished by its having the corolla-tube somewhat lengthened and cylindrical, and but slightly contracted or expanded. The lobes of the corolla are 5 in number, small, delicate, expanded flatly, and fringed at the edges. Their color ranges from whitish and purple to bright red or violaceous in the different species. These fragrant flowers are abundant and clustered in cymose or paniculate order. The valves of the capsule dehisce from

Fig. 73.

*Cinchona Calisaya.*

the base, from the splitting of the partition, the two divisions remaining attached to each other at the apex by means of the permanent 5-toothed calyx. The *cinchona trea*, or shrubs, are handsome, and have somewhat the appearance of the syringa bush. The leaves, which are of various shapes, from ovate or obovate to nearly circular, sometimes cordate, and, in some species, lanceolate, have always an entire margin (sometimes slightly revolute), and are of variable size and character, often on the same shrub. They are coriaceous, shining, laurel-like, finely-veined, and have a strong midrib. In some of the valuable species, in the vein-axils, near the midrib on the lower surface of the leaf, are small depressions, termed *scrobiculi*, which give out an astringent fluid. Hairy tufts replace these in some species. Often the young leaves are purplish, violet-colored underneath, and the mature leaves before falling assume rich tints of orange or crimson, this being marked in the *C. purpurascens*, Weddell. The petiole is thick, about $\frac{1}{2}$, or less the length of the leaf, and frequently of a handsome red hue. The most valued *cinchona* trees range from 40 to 80 feet high. They easily form hybrids, of which there are several, and so uniform are the characters of the members of the genus that it is extremely difficult to separate the individual species, which are so closely connected by intermediate forms which tend to form a somewhat connected series.

From the foregoing it will be seen that botanical classification has been difficult. The species number about 31. Weddell, whose views are generally accepted, enumerates 33 species and 18 subspecies, with varieties and subvarieties. Bentham and Hooker place the number at 36, De Candolle at 18 species, while Howard indicates 38. On the other hand, O. Kuntze (1882-3) contends for only 4 primary species, with their hybrids; a view, however, not universally accepted, and one based upon observation from cultivated Indian plants and herbarium specimens. The four species of Kuntze are: 1. *CINCHONA WEDDELIANA*. 2. *CINCHONA PAHUDIANA*. 3. *CINCHONA HOWARDIANA*. 4. *CINCHONA PAVONIANA*.

This agrees but little with the classification of Weddell, who condensed all of his species and subspecies of *Cinchona* into *stems* (*stirpes* or *souches*). To these fundamental groups, from which all the others radiate, he has placed the best known or most characteristic at the head of each. These *stirpes* or *stems* are: 1. *STIRPS CINCHONÆ OFFICINALIS*. 2. *STIRPS CINCHONÆ RUGOSÆ*. 3. *STIRPS CINCHONÆ MICRANTHÆ*. 4. *STIRPS CINCHONÆ CALISAYÆ*. 5. *STIRPS CINCHONÆ OVATÆ*. A comparative table will show the relation of Kuntze's classification to that of Weddell:

WEDDELL'S FORMS OF

1. *C. officinalis*
2. *C. rugosa*
3. *C. micrantha*
4. *C. Calisaya*
5. *C. ovata*

ARE DECLARED BY KUNTZE

Hybrids of *C. Weddelliana* with *C. Howardiana* and *C. Pavoniana*.
C. Pahudiana and hybrids.
C. Pavoniana and hybrids.
C. Weddelliana and hybrids.
C. Howardiana.

Kuntze's classification includes altogether 44 species and hybrids. Probably the most correct estimate of the number of species is that of Baillon, who places it at 20. The following conspectus, extracted by permission from the *Pharmacographia*, gives not only the *stirpes* of Weddell, but the species enumerated in each group, with source, where illustrated, and the barks known or believed to be derived from them:

Species (excluding subspecies and varieties) according to Weddell.	Where figured.	Native country.	Where cultivated.	Product.
I. STIRPS CINCHONÆ OFFICINALIS.				
1. <i>Cinchona officinalis</i> , Hook.	Bot. Mag., 5864.	Ecuador (Loxa).	India, Ceylon, Java.	Loxa or Crown bark. Pale bark.
2. <i>Cinchona macrocalyx</i> , Pav.	Howard, N. Q.	Peru.	{ Ashy Crown bark. Subspecies, <i>C. Pelton</i> , affords an im- portant sort called <i>Pelton bark</i> ; used in making quinine.
3. <i>Cinchona lucumefolia</i> , Pav.	do	Ecuador, Peru.	Carthagena bark, confounded with <i>Pelton bark</i> ; not so good.
4. <i>Cinchona tucumana</i> , R. et P. (?)	do	Peru.	{ Columbian bark. Imported for manufacture of quinine.
5. <i>Cinchona lancifolia</i> , Mutis.	Karsten, tab. 11, 12.	New Granada.	India.	{ Soft Columbian bark is produced by Howard's var. <i>oblonga</i> .
6. <i>Cinchona amygdalifolia</i> , Wedd.	Wedd., tab. 6.	Peru, Bolivia.	A poor bark, but not now imported.
II. STIRPS CINCHONÆ RUPESTRIS.				
7. <i>Cinchona pitayensis</i> , Wedd.	{ Karst., tab. 22. { (<i>C. Trianae</i>)	{ New Granada { (Popayan).	India.	Pinayo bark; very valuable; used by makers of quinine; it is the chief source of quinine.
8. <i>Cinchona rigida</i> , Pav.	Howard, N. Q.	Peru.	Bark unknown; probably valueless.
9. <i>Cinchona Mutisi</i> , Lamb.	do	Ecuador.	Bark not in commerce; contains only arbutin.
10. <i>Cinchona hirsuta</i> , R. et P.	Wedd., tab. 21.	Peru.	Bark not collected.
11. <i>Cinchona caribayensis</i> , Wedd.	Wedd., tab. 19.	Peru, Bolivia.	India, Java.	Poor bark; handsome appearance; propagation discontinued.
12. <i>Cinchona Fendleriana</i> , How.	Howard, N. Q.	Bolivia.	Bark not collected.
13. <i>Cinchona asperifolia</i> , Wedd.	Wedd., tab. 20.	Peru.	Bark not known as a distinct sort.
14. <i>Cinchona umbellulifera</i> , Pav.	Howard, N. Q.	do	do	do
15. <i>Cinchona glandulifera</i> , R. et P.	do	Peru.	False Loxa bark, Jaen bark. A very bad bark.
16. <i>Cinchona Humboldtiana</i> , Lamb.	do	do	An inferior bark mixed with <i>Calisaya</i> .
17. <i>Cinchona micrantha</i> , Wedd.	Wedd., tab. 8.	South Bolivia.	Bark formerly known as <i>Red Cusco bark</i> , or <i>Santa Ana bark</i> .
18. <i>Cinchona australis</i> , Wedd.	do	Peru.	Grey bark, Huanuco, or Lima bark. Chiefly consumed on the continent.
19. <i>Cinchona peruviana</i> , How.	Howard, N. Q.	Peru.	India India India	{ <i>Calisaya</i> bark, Bolivian bark. Yellow bark. The tree exists under many varieties; bark also very variable.
20. <i>Cinchona nitida</i> , R. et P.	do	Peru.	{ Carabaya bark. Bark scarcely now imported. <i>C. cuneata</i> , Miq. (flowers and fruit unknown) may, perhaps, be this species.

30. <i>Cinchona pubescens</i> , Vahl.	Wedd., tab. 16.	{ Ecuador, Peru, { Bolivia.	
31. <i>Cinchona purpurascens</i> , Wedd.	Wedd., tab. 18.	Bolivia.	

Cinchona Calisaya.—Weddell. This is a high tree, and if we accept the view of Weddell, also exists in a shrub form as var. *Josephiana*. Some botanists, however, regard the latter as distinct, or rather as belonging to no particular species. *Cinchona Calisaya* has an important variety largely cultivated in Java, known as the *Cinchona C. var. Ledgeriana* (named from Charles Ledger, who introduced it in Java), which is extremely rich in alkaloids. *C. Calisaya* is distinguished by its smooth, ovate capsules, scarcely equal in length to the flowers. *C. Boliviana*, Weddell, a variety of Bolivia, has leaves with a purplish under surface. (For description of *C. Calisaya* see *Amer. Disp.*, 15th ed.).

Cinchona Calisaya grows in declivities and steep and rugged places of the mountains, at an altitude of from 1500 to 1800 meters in the hottest forests of the valleys of Bolivia and Southern Peru; between 13° and 16° 30' south latitude, and from 68° to 72° west longitude; in the Bolivian provinces of Enquisivi, Yungas, Larecacha, and Caupolicon; and in the Peruvian province of Carabaya. It flowers in April and May. It yields the *Yellow cinchona bark*, commonly called indiscriminately by the Spaniards and Indians, *cascarilla calisaya*, *calisaya*, or *culisaya*.

Cinchona officinalis, Linné.—This species has suffered much at the hands of botanists, some contending that the name indicating the Linnéan species is capable of double interpretation (Flückiger). Hooker has made a new diagnosis regarded as differing from that of Linné, and the former's plant is now regarded by many as the true *Cinchona officinalis*. Others regard the diagnosis of Linné as correct. This was the original species of *Cinchona*. It has ribbed capsules. (For a description of this species, see *Amer. Disp.*, 15th ed.). It is indigenous to Ecuador and Peru, and is the source of *Loxa bark*. The *Loxa* region, however, according to Wellcome, is now exhausted.

Cinchona succirubra, Pavon, is a tall tree, from 50 to 80 feet high, indigenous to the western slope of Chimborazo, its territory of growth extending to northern Peru. It flourishes well in Ceylon, and the Blue Hills of India, being well adapted for grafting and hybridization. Its capsules are smooth. It is the source of *Red cinchona bark*.

History.—As a therapeutical agent of inestimable value, cinchona, from its first introduction and use to the present day, stands pre-eminent. In fact, no article of the *Materia Medica* has borne so high and unwavering a reputation. It is an agent for which, notwithstanding the vast addition to the list of the *Materia Medica*, no other substance has been discovered in nature nor in the laboratory that could fully substitute its therapeutical value.

The period of the discovery of the medicinal properties of cinchona, is unknown. Some fabulous stories are mentioned concerning it, but we have no reliable information as to when, or how it was discovered. Some writers (Geoffroy, Ruiz, and Joseph de Jussieu), are of the opinion that the Indians were acquainted with its medicinal properties prior to the arrival of the Spaniards; but even this is doubtful, for La Condamine, who visited Peru in 1738, found the natives then unacquainted with it; and J. J. Caldas, pupil of the celebrated botanist, Mutis, who traveled from 1802 for many years in the mountains of Peru in order to examine the natural history and geographical distribution of the *Cinchonas*, states that the Indians who inhabit those regions, and among whom fever often makes sad inroads, will not use it, believing that it heats the blood and humors; and states that the heaviest chastisements are often inflicted to compel them to employ it as a remedy; he remarks that this prejudice is much against the fact of their ever having been acquainted with its use, as they cling with the greatest obstinacy to their inherited customs, vices, and prejudices. Ulloa, and Humboldt also express the opinion that the Indians were unacquainted with the use of cinchona.

The introduction of cinchona into Europe dates from the year 1639; it came to be known, it is said, from its having cured the lady of the Comte de Chinchon, at that time Viceroy of Peru, of a fever, and who, upon her return to Spain, carried some of the bark with her. For some time after its introduction, the Jesuits, who received the bark from their brethren in Peru, alone used it, and kept to themselves the secret of its origin; and it was through their use of it that its fame as a febrifuge so rapidly spread, and from which fact it derived the name which still clings to it, of "*Jesuits' bark*." The medical profession at first opposed its use, and

it is recorded that it was not employed by them, until Sturm, of Antwerp, in 1639, and Bado, of Genoa, in 1663, advocated its employment and wrote in praise of its virtues. Notwithstanding the length of time that has elapsed since the discovery of the medicinal properties of cinchona bark, its botanical history is yet subject to discussion. A number of botanists have explored and described some of the sources of the barks of commerce, yet much remains to be accomplished. The barks that are recognized as official by the Pharmacopœias, both of this country and Europe, are now chiefly cultivated. Much of the information we have concerning them is from the labors of M. Weddell, who accompanied a scientific expedition, under the patronage of the French government, to Brazil and Peru in 1843, and who continued his researches until 1848, since which others have written descriptions, as M. Guibourt, E. Rampon, A. Delondre, G. Planchon, etc. but they have not materially differed from Weddell. Prior to him was Condamine, who first described the Cinchonas; Jussieu, Mutis, Ruiz, Pavon, Humboldt, and Bonpland. Weddell's researches (modified) having been adopted by many as authority, we shall, in the following text, give in a somewhat condensed form his manner of collecting the bark (see *Distribution and Collection*), and some remarks upon the classification of barks into red, yellow, and pale barks, as adopted generally in works upon *Materia Medica*.

Previous to the year 1775, Loxa bark (most probably derived from *Cinchona officinalis*), was the only kind of cinchona known in commerce. It was not until 1772 that Mutis discovered the valuable tree in the neighborhood of Santa Fé de Bogota, and at this period Europe began to receive Cinchonas direct from the ports of New Granada, on the Atlantic. Some years later the authors of *Flora Peruviana* (Ruiz and Pavon), studied the species of lower Peru, to the north of Lima, and these were also introduced into commerce. The only species then, which, botanically speaking, still remained unknown in Europe, were those growing in the vast extent of country extending southward. Notwithstanding the efforts of De Jussieu and the botanist, Thaddeus Haenke, little was added to the scientific knowledge of the Cinchonas by their travels. In the work by M. Weddell, he has made known the species observed by him in those regions during the years 1845, '46, and '47. From his observations, this *Cinchona* (Calisaya) does not spring up again in the localities from which it has been cut, the circumstances peculiar to its growth being, as it were, altered, and a stunted growth, the variety *Josephina*, is the only representative of the majestic *C. Calisaya* to be found in the localities which have been destroyed by the hands of the cascarrilleros in a very ruinous and wasteful manner. To remedy the evil, at least as far as lay in its power, the government of Bolivia prohibited the cutting of the bark from the year 1851 for three years; this, together with a monopoly by the government of all the bark then cut in its territory, caused a rapid rise in the value of calisaya bark, and forced the manufacturers of quinine to use other barks in its preparation.

The immense commercial demands on the Cinchonas of these parts, tending to exhaust the forests, also rendered it necessary that new sources should be discovered. According to Wellcome's report (Flückiger, 1884), the forests of Loxa, for example, are now exhausted of their cinchona trees. To give some idea of the consumption of this bark, and the enormous drain upon the localities from which it was obtained, the company which had a monopoly of it exported at one time annually, more than 850,000 pounds of it. The great extent of the country, however, over which the Cinchonas are spread, excludes the idea, which has been entertained, that we shall ever be deprived of this valuable drug, and the extensive Eastern cultivation now makes the contingency of its extinction next to impossible.

Cultivation.—The subject of cultivation of the Cinchonas early received the attention of botanists and laymen, both with a view to increasing the supply in their native country and their introduction into foreign climes. Condamine made an unsuccessful attempt to transport to Europe young trees, which, in transportation, were lost in the Amazon river. Mutis cultivated the tree, and the Bolivian Jesuits obligated the collectors to plant 5 trees in cross-form on the spots where each tree was felled. The same body of religionists from Peru, made unsuccessful attempts, in 1849, to grow the trees in Algeria. Later, however, several persons, chiefly among whom were Miquel, Pahud (Governor-general of Dutch East

Indics), Hasskarl, Weddell, Karsten, Royle, Markham, and Ledger, succeeded after innumerable and partly vain attempts, in establishing the plants, first in Java and afterward in India. It was with the greatest of difficulty and danger owing to the hostile attitude of the native population, that the plants, or seeds even, could be procured, and the transportation was attended with mishaps, either due to the perishing of the plants or seeds en route, or at stations, or to losses in the sea. The seeds sent by Weddell to Paris were planted in the gardens of Thibaut and Keteleer, and the plants grown therefrom were, in 1852, bought by the Dutch government and sent to Java. The results, however, were none too satisfactory, and it was not until Markham, already well acquainted with the territory, in 1859 went to South America to procure plants, that the foreign introduction of cinchona became at all successful. Upon reaching the cinchona lands he associated with him Spruce, a botanist, Prichett, a resident, and Cross (1861), a gardener, the latter planting with his own hand, in India, the plants procured by him in America. The plants secured by the latter were those of *C. succirubra*. Markham's purpose was to reserve for himself the Peru and Bolivia border-lands, and procure the *C. Calisaya*, of which he collected 456 young plants, amid great dangers and hardships, a graphic account of which is to be found in Markham's work on Peruvian Bark. These plants, which were shipped by way of England, however, in transportation from thence to Hindustan, became exposed to such intense heat while in the waters of the Red Sea, that they were of little value when planted. The deficiency was made up, however, by seeds of *C. Calisaya*, procured from Java, and the cultivation of the Cinchonas in India, Ceylon, and Java, became at last a marked success. The plants obtained by Prichett were from the Huanuco country, and were chiefly plants of *C. nitida* and *C. micrantha*.

The cultivation of the plants in their new homes is not without some drawbacks. According to F. B. Power, the Javan volcanic eruptions of 1883 did great damage to the cinchona plantations. In addition to such accidental injuries, a constant source of trouble is the beetles and caterpillars, as well as a new and small hemiptera, the "tea bug" (*Helopeltis Antonii*, Sigm.), the wingless young of which, hatched among the tops of the branches and leafstalks, nourish themselves at the expense of the leaves, producing a disease known as *kinarceet* (see *Cinchona Barks*, Flückiger, Tr. by Power).

The Cinchonas have been cultivated with some success at Jamaica, but the only commercially important ground in South America where cultivation is at all successful is in Bolivia. Western Africa and Mexico have also attempted the cultivation, the former with considerable success. Within a few years the estimated number of cultivated trees was about 75,540,000, Java alone possessing 30,000,000; Central America and Bolivia, each 2,000,000; India, 18,500,000; Ceylon, 19,000,000; Australia, Borneo, and other islands, 1,000,000; Africa, 2,500,000; Jamaica, 500,000, and Mexico the remainder. Only cultivated barks now appear in commerce, the wild bark being seldom met.

Distribution and Collection.—The native Cinchonas seem to be exclusively confined to the Andes within the boundaries of Peru, Bolivia, Ecuador, and New Granada, from 11° north latitude to 20° south latitude; chiefly growing at an elevation varying from 1200 to 10,000 feet above the level of the sea, and in a dry, rocky soil. There are at least 12 or 13 species, which have from time to time furnished the barks of commerce.

The only period in which these cinchona barks are collected, is during the rainy season, which continues some 3 or 4 months. The trees rarely constitute an entire forest, but form more or less compact groups in various parts of the forests, termed *manchas*. Frequently they grow separately. Experienced cutters, called *diestros* or *practicos*, are engaged to explore the forests, and report where the Cinchona trees are to be found, their number, and the quality of the bark they yield. This investigation requires much sagacity, patience, and experience, as the chances of success depend wholly upon the report made. So well skilled are these *diestros* that they can in most instances distinguish the trees by the appearance of their tops, by a peculiar slight movement of the leaves of certain species, by a particular color of the foliage, by the aspect presented by a great mass of inflorescence, etc. Sometimes they are favored with success in a short time, while at other times, many days pass before they can reach the object which they have

constantly kept in sight from the moment of its discovery. Matters having been satisfactorily ascertained, the merchant or company desiring to procure the bark, engage other parties who are called *cascarilleros*, and are trained to this occupation from infancy, to cut the bark for them. A road is at once made up to the point which is to form the center of operations, and the *cascarilleros*, together with a confidential agent of the company, called the *majordomo*, construct small huts or houses in a favorable site near this point, both for the purpose of encampment and to shelter their provisions and cuttings. And while the party are engaged in this neighborhood, all parts of the forest adjacent to the roads are considered the property of those who formed it, and no other *cascarilleros* are allowed to work there. The trees are felled with hatchets, being cut a little above the root, the bark having been previously removed from this part, even removing the earth from around the trunk that the barking may be more complete. As soon as all obstacles to the falling of the tree have been overcome, and it lies upon the ground, the useless branches are cut off, and the peridermis is removed by striking it with a wooden mallet, or the back of a hatchet, which exposes the inner bark; frequently this is further cleaned by means of a brush.

The bark is then divided by incisions circumscribing the pieces to be removed, the size and regularity depending upon circumstances, but generally for convenience of transport and facility of preparation they are made from 15 to 18 inches long, and 4 or 5 inches wide. These pieces are removed from the trees, with a common knife or similar instrument, and as close to the wood as possible. The bark of the branches is similarly removed, except that its peridermis is not beaten off. The thinnest bark from the branches is dried by exposure to the sun's rays, and forms hollow cylinders; but the pieces of thicker bark, which are to form the flat cinchona, *tabla* or *plancha*, are, after a slight exposure to the sun, placed one on the other in crossed squares, upon the top of which a heavy weight is placed. This exposure and pressure is repeated for several days until the bark is flattened and completely dried. This is the process more commonly adopted, yet it will sometimes vary a little, according to the locality, or the nature of the tree operated upon. Thus, the peridermis may be simply scraped, or be only partially removed; the bark may be imperfectly or not at all pressed; or it may be imperfectly desiccated, thereby destroying its value, etc. The bark prepared, is carried by the *cascarilleros* in heavy shoulder loads to the camp, which is an inconceivably laborious task, frequently requiring 15 or 20 days for its removal from one district alone. It may be proper to state here, that, as a rule, before the bark reaches the coast, it passes through at least three or four hands, and on each occasion its price is augmented; its carriage from the coast being expensive, and having to pass through other hands also, a pound of the bark that would cost at the coast a certain price, is sold in Europe for the price many times doubled.

As the bark is brought into camp by the cutters, it is examined by the *majordomo*, who, after rejecting that part of it which is bad, submits it, if necessary, to a fresh process of drying. It is then formed into bundles of nearly equal weight, sewn up in coarse canvas, and conveyed on the backs of men, donkeys, or mules, to the depots in the towns, where they usually receive an exterior envelope of fresh hide, which, as it dries, forms the hard compact packages in which the bark is exported, termed *aerones*. Such is the history of the original method as pursued in South America.

The East Indian and Java methods are three: *Mossing*, *felling* or *coppicing*, and *shaving*. The first method, proposed by Karsten and put into operation by W. G. MacIvor, consists of removing from the stems narrow vertical strips of the bark. The denuded surface is then enveloped with moss (clay is now being used in India and Alang-Alang grass in Java) when the bark is quickly renewed, and becomes richer in alkaloidal principles. The second method (*coppicing*) consists in felling the trees and stripping them of bark, while the stumps so left send up shoots, which, in about 8 years, yields a rich bark also. This method is employed in Bolivia to some extent; when the roots are utilized also the process is called *uprooting*. The third method, introduced in Java by Bernelot Moens (1880), is that of *shaving* or *scraping*, which consists in removing not the whole of the bark, but a few layers, leaving enough of it to preserve the vitality of the tree. The effect of these methods has been a greatly increased yield of alkaloids.

Classification of Barks.—In most works on *Materia Medica*, we find the cinchona barks classified according to their color, i. e., into the *yellow, pale* and *red barks*; the *Cinchona Calisaya*, as yellow bark; the *C. officinalis*, and others, as pale barks; and the *C. succirubra*, as red bark. This classification, while convenient, is very defective; not only does it, in some instances, separate the products of the same tree, but it connects those which are essentially different. At one time it was thought that all the gray cinchonas were furnished by the same species, but not only are they produced by many different species, but very frequently they are the young bark of the same trees which yield the yellow and red cinchonas. A more useful and, indeed, more natural classification would be founded, in the first instance, upon the chemical composition of the barks, it being only necessary to study their active principles, as quinine, cinchonine, etc. But this method is impracticable on account of the unavoidable difficulties arising from such a mode of classification, and, also, from the fact now fully proved, that the same botanical species furnish barks varying greatly, according to accidental circumstances. Weddell remarks that if a classification be absolutely needed, one which should be based upon the anatomical structure of the bark would be of much greater utility than either of the preceding, inasmuch as we shall find existing, even in the cinchonas, a certain relation between their structural and chemical characters. M. Weddell gives the data upon which he bases the latter conclusion which, however, can not be here discussed. The classification of commercial cinchona barks, according to their color, has been most generally accepted. At the present day such a classification is even more easily made than in earlier days, for the various sources and conditions of the bark caused the colors to vary greatly, and even to merge closely into one another. The color was chiefly based upon the powder rather than upon the exterior of the bark. The botanical sources of the three grades are now, however, well known on account of their being cultivated. To those species, with their hybrids, which have become official, may be added mention of an inferior bark now known as *hard yellow*, or *Maracaibo bark*. These distinctions into red, yellow, etc., are mainly taken cognizance of by pharmacists, the manufacturers of alkaloids caring but little for classification, their reliance being placed upon all barks which, by assay, will yield them the greatest amount and best quality of bases. A convenient classification is that less in vogue known as *druggists' barks* (quills, or large chips), and *manufacturers' barks* (broken bark). In general, barks occur in commerce in 5 chief forms: (1) small chips or fragments, which includes much of the broken bark and pieces of root bark; (2) shaved bark, which includes largely barks of branches and dry stems, with some root bark; (3) irregular flat chips or pieces of varying sizes and shapes, mostly made up of hard yellow bark; (4) the cultivated, together with some wild bark, in the form of quills, taken from stem and root; (5) and lastly, the thick, mossed bark and thinner renewed bark, obtained by the mossaing process. Making allowances for different conditions existing at the time of gathering, such as the age of the plant, etc., the following descriptions will apply to the barks as classified according to color:

Description of Barks.—**YELLOW BARK** (*Calisaya bark, Cinchona flava*), from *C. Calisaya* and its variety *Ledgeriana*. Mostly cultivated, rarely collected wild, in great demand, and greatest quinine yielder (70 to 80 per cent of whole yield of alkaloids). The best bark; the *quill* forms only commercial, the *flat*, or *table bark*, being rarely met at present (see below). Large, handsome quills, sometimes broken, varying from 18 to 30 inches long, and from $\frac{1}{4}$ to $\frac{1}{2}$ inch thick, and occasionally $2\frac{1}{2}$ inches wide; color gray, or light-brown gray externally, pale cinnamon-brown internally, the inner surface marked with very fine striæ. Its powder is a pale, yellow-brown. The *quilled bark* may be in fragments varying from 1 or 2 inches to 24 inches in length, from 2 lines to 2 inches in diameter, and from $\frac{1}{4}$ to 7 lines in thickness. Very small quills, however, are very rare. They are generally singly quilled, though occasionally met with doubly quilled. Usually *coated*, with an outer bark or periderm; sometimes *uncoated*, or deprived of its periderm; the inner, living part of the bark, Weddell terms its *derm*, in contradistinction to its external covering, or *periderm*.

In the *coated* specimens, the periderm varies in thickness, is more or less rugous, and marked with transverse impressions, furrows, or cracks, which some-

times form complete rings around the quills. The edges are thick, everted, and raised. If the periderm is very thick, the consistence of it is corky or elastic, and the annular furrows have the appearance of deep incisions. Between these annular markings are longitudinal wrinkles or cracks. In the large quills, these furrows and cracks give the bark a very rough character (the so-called carved, or chicken-legged appearance), by which it may easily be distinguished from the large quills of gray bark (*Huanuco*). The periderm is nearly tasteless, having a naturally brown color, but sometimes more or less gray or silvery from the crustaceous lichens with which it is covered.

The flat, or *uncoated* bark, consists chiefly of liber; its taste is very bitter and feebly astringent; its transverse fracture, externally, is resinous, internally fibrous. The color is brown externally, and it is marked with impressions corresponding to the furrows or cracks of the periderm. Internally, it is finely fibrous, and of a deep cinnamon-brown color.

PALE BARK (*Loxa bark*, *Loja bark*, *Crown bark*, *Huanuco bark*, *Cuenca bark*). From *Cinchona officinalis*. Cultivated largely in India, and collected wild in Ecuador in former times, chiefly around Loxa. Large quinine yielder (60 to 70 per cent of whole yield of alkaloids). Entire or broken (irregularly), single or double quills 3 to 15 inches long, by $\frac{1}{4}$ to $\frac{1}{2}$ or 1 inch in diameter, chiefly 1 or 2 lines in thickness, but very variable in this respect. Its periderm is darker than in other species, and its powder light-brown. More lichens are present upon it than upon other barks, rendering it shaggy, and sometimes a portion of the ridges are verrucose. Its fissures are broader and more open than in the preceding bark, nor does it contain but a few longitudinal cracks, and is therefore not "checkered or chicken-legged" in appearance. The upper surface of the bark is very variable. According to age, temperature, and locality, it varies from a *light-brownish* color to *black*. If the trunk and branches are much exposed to the sun and wind, the bark becomes black, and if the tree is closely surrounded by other trees, it assumes a brownish color, which varies to a light-yellowish gray. A large quantity of lichens grow on the whole of the surface. On the epidermis, whatever its color may be, annular impressions or furrows are always perceptible, although sometimes but slightly impressed. They are the traces of places where the stipules were situated. Immediately beneath each ring are two almost circular cicatrices, formed by the petiole after the fall of the leaves. Between the rings many other transverse furrows and cracks, varying in length, depth, and distance from each other, are perceived, mostly parallel to the rings, but never extending entirely around the trunk. All these characteristics of the surface are also found on other species of *Cinchona*, and are therefore insufficient of themselves to distinguish any species. On the inner smooth surface, which is formed of fine, parallel, longitudinal fibers, we perceive numerous whitish spots, some of which are shining, but most of them dull. The color of this surface is similar to that of dry cinnamon, passing rather into yellow when the bark is fresh. The edges of the fractured surface of the bark are sharp, like grass, and only here and there a small point is perceptible on the inner edge. Under a magnifier the epidermis appears attached (*gebunden*), blackish, and shining; the subjacent parenchyma, which forms a concentric ring, is thicker than the epidermis, sometimes blackish, sometimes brownish-yellow with many shining spots. Next follow the layers formed of parallel fibers, between which we observe shining points, which proceed from the gummy, resinous juice diffused through the entire bark. This is the only official species which has an odor, which, in this bark is distinct and characteristic. J. J. Caldas, writing in 1802, states: "The natives call it *casca-rilla fina amarilla* and never quina. It flowers very probably twice, in July and August, and in December and January. The leaves fall successively, as is the case with most equinoctial plants. By the epithet *amarilla fina* it is distinguished from *colorada fina*, which differs from the typical principal form by the color of the fresh bark, which is reddish, whereas the other is yellow. This quality, however, does not appear to be permanent, for when the amarilla is dried it assumes the color of the other sort, so that the most experienced person is unable to distinguish (by color alone) one from the other."

RED BARK (*Cinchona rubra*).—From *C. succirubra*. Chiefly cultivated, except in South America. Yields an abundance of alkaloids, but of quinine only about

2 per cent. Quills thicker and wider than calisaya, otherwise quite similar, and the inner surface of a much redder cinnamon-brown than that species. Yields a reddish-brown powder. Transverse fissures few or none; when present disposed irregularly not forming a checkered or chicken-legged appearance. The prominent suberous, warty ridges, often short and merging into each other, and the elongated furrows between the ridges are distinguishing features (see *Official Description*).

The hybrid barks vary somewhat from these descriptions. *Cinchona rubra* is very largely hybridized with *C. officinalis* and vice versa, and with *C. Calisaya* and its variety *Ledgeriana*. The hybrids with the former are lighter in color, and show the transverse fissures. The hybrids of the latter species with *C. succirubra* yield a bark in which the characteristics of the latter are most prominent. (For the other known barks and their sources, see *Conspectus*, already given). The U. S. P. has combined the medicinal cinchonas into two classes, made official as follows:

I. CINCHONA (U. S. P.).—"In quills or incurved pieces, varying in length and usually 2 or 3 Mm. ($\frac{1}{8}$ or $\frac{1}{4}$ inch), or sometimes 5 Mm. ($\frac{1}{2}$ inch) thick; the outer surface covered with a gray or brownish-gray cork, usually slightly wrinkled, marked with transverse, and also with intersecting, longitudinal fissures (*C. Calisaya*), and sometimes with scattered warts and slight longitudinal ridges; inner surface light cinnamon-brown, very finely striate; fracture short and granular in the outer layer, and finely fibrous in the inner layer; powder light-brown or yellowish-brown; odor slight, somewhat aromatic; taste bitter and somewhat astringent"—(U. S. P.).

II. CINCHONA RUBRA (U. S. P.) *Red cinchona*.—"In quills or incurved pieces, varying in length, and from 2 to 4 or 5 Mm. ($\frac{1}{8}$ to $\frac{1}{4}$ or $\frac{1}{2}$ inch) thick; the outer surface covered with grayish-brown cork, more or less rough from warts and longitudinal warty ridges, and from few, mostly short, transverse fissures; inner surface more or less deep-reddish-brown and distinctly striate; fracture short-fibrous in the inner layer; powder reddish-brown; odor slight; taste bitter and astringent"—(U. S. P.).

The *Maracaibo* or *Hard yellow bark* (*Puerto Cabella bark*), of uncertain derivation, is a wild bark yielding very little quinine, and unimportant so far as its consumption in this country is concerned. It may be employed for the extraction of alkaloids other than quinine, is very bitter, and is used in some countries in the preparation of *Huxham's Tincture*.

Chemical Composition.—I. GENERAL CHEMICAL HISTORY. The very earliest chemical examinations of Peruvian bark were directed to the determination of amounts of resinous and extractive bodies, and the action of menstrua upon it. However, very early attempts were made to separate a febrifuge principle, but without success. The first alkaloidal principle isolated from cinchona was *cinchonine*, the existence of which had been pointed out, in 1803, by Dr. Duncan, of Edinburgh; it was first isolated and obtained in a state of purity by Gomez, a physician of Lisbon. He attributed the efficacy of cinchona barks to the presence of this body; but he failed to recognize its alkaline character, which, indeed, was not fully appreciated till after the discovery of morphine was announced by Sertürner, in 1816, when an impetus was given to investigations for alkaloids. Toward the year 1820, Pelletier and Caventou pronounced the alkaloidal character of cinchonine, an observation which was communicated to them by Houton-Labillardière; at the same time these chemists made the important discovery of *quinine*. About twelve years later two other French chemists, M. M. Henry and Delondre, discovered in yellow cinchona bark a third alkaloid to which they gave the name of *quinidine*. In 1829, Sertürner, already celebrated by his discovery of morphine, observed in the mother-liquors of sulphate of quinine an encrystallizable base, which he called *quinoidine*, and to which he attributed wonderful febrifuge properties. This last substance *quinoidine* (or more properly *chinoidin*), was undoubtedly a distinct amorphous base, but the name was shortly afterward applied to a deep-brown, brittle mass obtained by precipitating the mother-liquors from quinine works with ammonia, the substance so obtained being a mixture of alkaloids, subsequently found to be chiefly *dicinchonine* ($C_{22}H_{24}N_2O_8$), and *diconchinine* ($C_{20}H_{22}N_2O_8$). Quinoidine was formerly used in medicine under the name *amorphous quinine*. Resinous matter, as well as the *amorphous* and artificial

constituents, were contained in it (see *Chinoidinum*). In 1847 Winckler obtained a new alkaloid from Maracaibo bark, to which he gave the name *quinidine*. Pasteur, however, in 1853, proved this to be different from the quinidine already known, and affixed to it the name *cinchonidine*. A number of alkaloids have since been isolated from the various species of cinchona (see below).

The discovery of alkaloidal principles in cinchona is antedated by the isolation of a peculiar and comparatively inert acid by Fr. Chr. Hofmann, in 1790, who gave it the name *Chinasäure* (*kinic acid*). A (calcium) salt of this acid was first observed in a sediment from an extract of cinchona, by Count de Laragaye, as early as 1745. Another discovery of early date is that of *chinorin* (*quinovin* or *kinovin*), by Pelletier and Caventou, in 1821, who named it *acide quinovique*, having obtained it from the bark of *Cinchona nova surinamensis*. It is a non-crystallizable, bitter principle which was later ascertained to be a glucoside (see below).

As a matter of history we retain the following results of some of the early investigators: Bucholz found in cinchona bark (Loxa), cinchonine 0.36, kinic acid 1.17, kinate of calcium 1.30, hard resin (red cinchonic) 9.97, bitter soft resin 1.56, fatty matter with chlorophyll 0.78, tannin with some chloride of calcium (?) 5.80, gum 4.43, starch a trace, lignin 74.43. According to M. M. Pelletier and Caventou, the pale, yellow and red barks contain kinate of quinine, kinate of cinchonine, soluble cinchona-red, or cincho-tannic acid, insoluble cinchona-red, yellow coloring matter, grass-green coloring matter, kinate of calcium, starch, gum, and lignose.

II. THE CINCHONA ALKALOIDS.—More than 40 alkaloids, both natural and artificial, have been derived from cinchona, cuprea, and related barks. Of these, those existing in greatest amount and of medicinal value, are but 4, viz.: *Quinine*, *quinidine* (Hesse's *conquinine*), *cinchonine*, and *cinchonidine* (*quinidine*); two others of importance are *quinamine* and *conquinamine* (*conchinamine*). Of these the first two are isomeric, and the third and fourth are likewise isomeric, comprising two main groups of cinchona alkaloids, one or more of the alkaloids of which are found in the cinchona barks.

The following tabulated statement indicates the numerous alkaloids with their composition and some points of interest connected therewith:

Alkaloids.	Composition.	Discoverer.	Source.
1. QUININE	$C_{20}H_{21}N_3O_2$	Pelletier and Caventou, 1820.	
2. QUINIDINE (Hesse's <i>Conchinine</i>).	$C_{20}H_{21}N_3O_2$	Henry and Delondre, 1833.	
3. CINCHONINE.	$C_{19}H_{21}N_3O$	Gomez, 1812; Pelletier and Caventou, 1820.	
4. CINCHONIDINE.	$C_{19}H_{21}N_3O$	F. L. Winckler, 1847.	Maracaibo bark.
5. QUINAMINE.	$C_{19}H_{21}N_3O_2$	Hesse, 1872. }	<i>Cinchona succirubra</i> and
6. CONQUINAMINE (<i>Quinamidine</i>) (Hesse's <i>Conchinamine</i>).	$C_{19}H_{21}N_3O_2$	Hesse, 1877. }	<i>Crosulenta</i> .
7. HOMOQUININE (<i>Ultraquinine</i>).	$C_{19}H_{23}N_3O_2$	Tod, Howard, Hodgkin, Paul, Cownley and Whiffen, 1882.	<i>Cinchona cuprea</i> .
8. CUPREINE.	$C_{19}H_{23}N_3O_2$	Paul and Cownley.	<i>Cinchona cuprea</i> .
9. HYDROQUININE.	$C_{20}H_{23}N_3O_2$	Hesse.	
10. HYDROQUINIDINE.	$C_{20}H_{23}N_3O_2$	Forst and Boehringer	Derived from quinidine.
11. HYDROCINCHONINE.	$C_{19}H_{21}N_3O$	Caventou.	Derived from cinchonine. Exists in Cuprea bark (Hesse).
12. HYDROCINCHONIDINE (<i>Cinchamidine</i>).	$C_{19}H_{21}N_3O$	Hesse, 1881.	
13. CINCHONAMINE.	$C_{19}H_{21}N_3O$	Arnaud, 1881.	<i>Remijia Purdieana</i> .
14. CINCHOTINE.	$C_{19}H_{21}N_3O$	Hesse, 1882.	
15. HOMOCINCHONINE.	$C_{19}H_{23}N_3O$	<i>Cinchona rosulenta</i> .
16. HOMOCINCHONIDINE.	$C_{19}H_{23}N_3O$	Hesse, 1877.	<i>Cinchona rosulenta</i> .
17. CUSCONINE.	$C_{22}H_{27}N_3O_4$	Hesse, 1877 (Leverköhn, 1829 [?]).	Cusco and Cuprea barks.
18. CUSCONIDINE.	$C_{22}H_{27}N_3O_4$	Hesse, 1877.	

Alkaloids.	Composition.	Discoverer.	Source.
19. CONCUSCONINE.	$C_{22}H_{22}N_2O_4$	Hesse, 1883.	Cuprea bark.
20. CONCUSCONIDINE.	$C_{22}H_{22}N_2O_4$	Hesse, 1883.	Cuprea bark.
21. CUSCAMINE.	Not analyzed.	Hesse, 1880.	Cusco bark.
22. PAYTINE.	$C_{22}H_{22}N_2O + H_2O$	Hesse, 1870.	Payta, or White Cinchona bark.
23. PAYTAMINE.	$C_{21}H_{21}N_2O$		
24. PARICINE.	$C_{16}H_{16}N_2O$	Winckler, 1845.	Para bark.
25. DICINCHONINE.	$C_{26}H_{44}N_4O_2$		
26. ARICINE (Marsini's Cinchovatine).	$C_{26}H_{26}N_2O_4$	Pelletier and Carlot, 1829.	Cusco and Cuprea barks.
27. DIQUINIDINE (Hesse's Dicinchonine).	$C_{40}H_{40}N_4O_2$		
28. CHAIRAMINE.	$C_{22}H_{22}N_2O_4$	Hesse, 1885.	<i>Remyia Purdieana</i> .
29. CHAIRAMIDINE.	$C_{22}H_{22}N_2O_4$	Hesse.	
30. CONCHAIRAMINE.	$C_{22}H_{22}N_2O_4$	Hesse.	
31. CONCHAIRAMIDINE.	$C_{22}H_{22}N_2O_4$	Hesse.	
32. CUSCAMIDINE.	Not analyzed.	Hesse, 1880.	Cusco bark.
33. JAVANINE.	Not analyzed.	Hesse, 1877.	<i>Cinchona Calisaya</i> var. <i>Javanica</i> .
34. DIHOMOCINCHONINE.	$C_{26}H_{44}N_4O_2$	<i>Cinchona rosulenta</i> .
35. CINCHOLINE.	Not analyzed.	Hesse, 1882.	Quinine mother-liquors.
DERIVATIVES.			
36. CINCHONICINE.	$C_{19}H_{22}N_2O$	Derived from cinchonine and cinchonidine.
37. DICINCHONICINE.	$C_{26}H_{44}N_4O$	Derived from cinchonine and cinchonidine.
38. HOMOCINCHONICINE.	$C_{19}H_{22}N_2O$	Derived from homocinchonidine sulphate.
39. APOQUINAMINE.	$C_{19}H_{22}N_2O$	Derived from quinamine, or conquinamine.
40. QUINICINE.	$C_{20}H_{24}N_2O_2$	Derived from quinine and quinidine.
41. DIQUINICINE.	$C_{40}H_{40}N_4O_2$	Derived from quinine and quinidine.
42. QUINAMICINE.	$C_{19}H_{24}N_2O_2$	Derived from quinamine sulphate.
43. PROTOQUINAMICINE.	$C_{17}H_{20}N_2O_2$	Hesse.	Derived from quinamine sulphate.

The first 35 alkaloids in the preceding table are regarded as naturally existing in cinchona, cuprea and related barks; the first 4 only are employed medicinally; the last eight are the artificially produced alkaloidal bases. According to Flückiger (*Cinchona Barks*, p. 64), "every cinchona bark contains amorphous alkaloids." The majority, however, are crystallizable.

Of the cinchona alkaloids, four are considered elsewhere under their respective heads, or as sulphates. These are *Quinine*, *Quinidine*, *Cinchonine*, and *Cinchonidine*. The others will be briefly considered here.

QUINAMINE ($C_{19}H_{24}N_2O_2$) (*Quinamia* or *Chinamine*).—Long, white, asbestos-like, nearly tasteless crystals; dextrogyre; anhydrous; its solution in diluted sulphuric acid is not fluorescent. Somewhat soluble in boiling water, nearly insoluble in cold water, soluble in ether, benzol, and benzin, most readily when hot, depositing crystals on cooling and evaporating; hot alcohol dissolves it, depositing crystals on cooling, the solution being alkaline; soluble in caustic potash solution and in ammonia. With hydrochloric and sulphuric acids it forms salts, their solutions being very bitter. Gold chloride precipitates solutions of the hydrochlorate yellowish-white, changing to purple, while gold is liberated; the solution at the same time turns purple-red. Boiled with diluted sulphuric acid it changes to isomeric noncrystallizable *quinamidine*, behaving similarly to quinamine with gold chloride; quinamine sulphate heated to the boiling point of water changes to *quinamicine*, also isomeric. The sulphate heated to 120° C. (248° F.), or higher, forms *protoquinamicine*. *Apoquinamine* is produced when *quinamine* or *quinamicine* is treated with hydrochloric acid, resulting in the abstraction of water. Quinamine fuses at 172° C. (341.8° F.).

APOQUINAMINE ($C_{20}H_{22}N_2O$).—Foliaceous, white, easily soluble in ether, diluted hydrochloric acid and alcohol. Its gold chloride double salt does not change to purple. Its amorphous hydrochlorate dissolves readily in water. Apoquinamine is isomeric with *homocinchonidine*, *homocinchonine*, and *homocinchonicine*. It is an artificial base.

HOMOQUININE ($C_{19}H_{21}N_2O_2$) (*Ultraquinine* of Whiffen). Obtainable from cuprea bark. Crystalline, soluble freely in chloroform and alcohol, but sparingly in ether, from which solvent it may be crystallized. Diluted sulphuric acid dissolves it, the solution giving the thalleioquin reaction (see *Quinine*). It is extremely levogyrate, and fuses at 177°C . (350.6°F). Its sulphate, like that of quinine, forms a fluorescent solution in water; the salt when freshly prepared, is soluble in ether (difference from quinine sulphate). The cold saturated solution of the sulphate in water is precipitated by Rochelle salt, thus behaving like quinidine and cinchonidine (*Amer. Jour. Pharm.*, 1882, p. 75).

CINCHONAMINE ($C_{19}H_{21}N_2O$).—Associated with cinchonine. A dextrogyrate base, discovered by Arnaud, in 1881, in the bark of *Remijia Purdieana*, and said to have sialagogue properties, and to be much more toxic than quinine. Readily soluble in hot alcohol, less so in cold alcohol (1 in 30), and in ether (1 in 100). It fuses at 184° to 185°C . (363.2° to 365°F) (Arnaud). It is usually extracted from the bark with milk of lime, the magma dried, boiled with alcohol, treated with hydrochloric acid, and crystallized as hydrochlorate. Water and diluted alcohol sparingly dissolve its crystalline salts, the sulphate being an exception.

CINCHOTINE ($C_{19}H_{21}N_2O$) is obtained by oxidizing crude cinchonine sulphate with potassium permanganate in the cold, which leaves cinchotine unaffected. It agrees with Willms' and Caventou's *hydrocinchonine*, which see.

HYDROQUINIDINE ($C_{20}H_{23}N_2O_2 \cdot 2\frac{1}{2}H_2O$), (*Hydroconchinine*), forms efflorescing crystals soluble freely in chloroform and hot alcohol, but less so in ether. It is dextrogyrate, gives the thalleioquin reaction, is fluorescent in sulphuric acid solution, and fuses at 168°C . (334.4°F) (Hesse). It is present, according to Forst and Boehringer (1882), in commercial quinidine, from which it is obtained by oxidation with potassium permanganate in acid solution.

HYDROCINCHONINE ($C_{19}H_{21}N_2O$).—Obtained by the action of sodium amalgam upon cinchonine acetate in alcoholic solution. Soluble in ether, alcohol, and water (1 in 1800).

HYDROCINCHONIDINE ($C_{19}H_{21}N_2O$).—This base is found in commercial cinchonidine together with homocinchonidine.

CUPREINE ($C_{19}H_{21}N_2O_2$). Isomeric with homoquinine. Crystallizes from ether with 2 molecules of H_2O ; from alcohol, anhydrous. Soluble readily in alcohol; sparingly in chloroform or ether. Solutions alkaline, give thalleioquin coloration, and are levogyrate; the alcoholic solution strikes red-brown with chloride of iron. It forms a crystallizable sodium compound ($C_{19}H_{21}N_2O.ONa$), which is mainly of theoretical interest.

HYDROQUININE ($C_{20}H_{23}N_2O_2 \cdot H_2O$) occurs in the mother-liquors from the manufacture of quinine sulphate; it has been found present in commercial quinine sulphate to the extent of 4 per cent (Hesse). According to Allen's method, purification of quinine from hydroquinine is effected by allowing the quinine to crystallize as acid sulphate, whereby hydroquinine remains in solution. Ether and alcohol dissolve it, it exhibits the thalleioquin reaction, is fluorescent in sulphuric acid solution, and fuses at 168°C . (334.4°F). Potassium permanganate does not affect it when cold.

HOMOCINCHONINE ($C_{19}H_{21}N_2O$) (Koch's *Cinchonidine*).—This body has been confounded with *cinchovatine* (*aricine*). From alcohol it forms large prismatic crystals, having a left-handed rotation. Salts partly amorphous.

DIHOMOCINCHONINE ($C_{20}H_{23}N_2O_2$), is amorphous, and exhibits a right-handed rotation with polarized light.

HOMOCINCHONIDINE ($C_{19}H_{21}N_2O$) occurs in large prisms, and is said to form the chief part of the *cinchovatine* (*aricine*) of Winckler. It is levogyre, its sulphate crystallizes in gelatine-like needles, holding $6H_2O$, and soluble in hot water.

PAYTINE ($C_{20}H_{23}N_2O \cdot H_2O$), a crystalline body, and **PAYTAMINE**, from a species of *Aspidosperma* called *Payta* or *White cinchona bark*. The latter is amorphous, and both are levogyrate, and form insoluble double salts with chloride of platinum,

thus differing from quinamine which they resemble in solubility in ether and in the instability of the double salts they form with gold chloride.

PARICINE ($C_{11}H_{18}N_2O$), a yellowish powder, was isolated by O. Hesse from the bark of *C. succirubra*, of Darjeeling, associated with quinamine and other bases. When fresh, ether will dissolve it, and nitric acid changes it to a deep-green, resinous material. It is separated from its associated alkaloids by means of sodium carbonate, the paricine precipitating first. Paricine closely resembles aricine, but differs in being more soluble in ether, and being uncrystallizable.

CUSCONINE ($C_{22}H_{32}N_2O_4$). A crystallizable body soluble in chloroform, alcohol, and ether, and scarcely at all in water. It has been believed to be identical with aricine, but differs from most cinchona bases in its salts being gelatinous and not dissolved by sulphuric acid. Its neutral sulphate is yellow, gelatinous, non-crystalline, and insoluble in sulphuric acid in excess. Accompanying it in Cusco bark, besides aricine, is CUSCONIDINE, an amorphous, yellow body. CONCUSCONINE ($C_{22}H_{32}N_2O_4$) from *Remijia Purdieana* (Hesse), is crystalline and tasteless.

CUSCAMINE is crystalline, easily soluble in hot alcohol, ether, and chloroform, and insoluble in nitric and oxalic acids. It fuses at $218^\circ C.$ ($424.4^\circ F.$).

CUSCAMIDINE is amorphous, and otherwise agrees with the preceding in solubility, etc.

ARICINE (Manzini's *Cinchovatine*) ($C_{22}H_{32}N_2O_4$) forms salts which are not readily soluble. This body, as cinchovatine, was found in Arica bark by Pelletier and Coriol in 1829. Aricine crystallizes in white, non-volatile needles, fusible at $187.7^\circ C.$ ($370^\circ F.$), insoluble in water, and soluble in ether; forms a characteristic acetate and acid oxalate.

DICINCHONINE ($C_{28}H_{44}N_4O_2$) is one of the constituents of commercial chinoidine, the chief other one being DIQUINIDINE (Hesse's *Diconchinine*) ($C_{26}H_{42}N_4O$). It is dextrogyre, fluorescent in solution, and does not give the thalleioquin coloration. Was found by Hesse (see *Amer. Jour. Pharm.*, 1885), especially in the bark of *C. rosulenta*.

QUINAMIDINE ($C_{15}H_{24}N_2O_2$) (*Conquinamine*, *Quinamidia*, or Hesse's *Conchinamine*). Forms long, lustrous, prismatic crystals, fusing at $123^\circ C.$ ($253.4^\circ F.$). With gold chloride it behaves like quinamine. It is non-fluorescent, and gives no thalleioquin reaction. It is obtained from the barks of *C. succirubra*, *C. rosulenta*, and other India barks. An amorphous *quinamidine* (isomeric) is produced as stated under *quinamine*. It forms a sparingly soluble hydrochlorate.

QUINAMICINE ($C_{15}H_{24}N_2O_2$) is amorphous, white, melts at $100^\circ C.$ ($212^\circ F.$), and is soluble in acids, from which it may be precipitated by sodium bicarbonate. It is obtained by heating quinamine with diluted acids.

PROTOQUINAMICINE ($C_{17}H_{26}N_2O_2$) is a brown amorphous body precipitated from its sulphuric acid solution by sodium carbonate. Ether does not dissolve it. Water scarcely dissolves its sulphate. An artificial product.

JAVANINE.—Crystallizable, easily dissolved by ether, and forms an intense yellow solution in diluted sulphuric acid. Occurs in *C. Calisaya* var. *Javanica*.

CINCHOLINE.—A pale-yellow, volatile oil, tasteless, yet of alkaline reaction, easily dissolving in ether, chloroform, and alcohol; little soluble in water. This alkaloid has the odor of chinoline.

CINCHONICINE ($C_{19}H_{28}N_2O$) is formed when cinchonine or cinchonidine is fused in the presence of acids. It is isomeric with these bodies. It is amorphous, soluble in alcohol, water, and especially in ammonium salts; dextro-rotatory.

DICINCHONICINE (*Apodicinchonine*). One of the constituents of commercial chinoidine.

QUINICINE ($C_{20}H_{28}N_2O_2$). Amorphous, very soluble in alcohol, little soluble in water, dextrogyrate, its sulphuric acid solution non-fluorescent.

CHAIRAMINE ($C_{22}H_{30}N_2O_4.H_2O$). White acicular crystals, soluble in chloroform and ether.

CONCHAIRAMINE ($C_{22}H_{30}N_2O_4.H_2O.C_2H_5O$). Forms crystals containing both water of crystallization and alcohol of crystallization. Hot alcohol, chloroform, and ether dissolve it. A mixture of sulphuric and molybdic acids dissolves the alcoholate, the solution being first brown, changing to deep-green.

CONCHAIRAMIDINE ($C_{22}H_{30}N_2O_4.H_2O$). White needle-crystals soluble in ether, chloroform, alcohol, benzene, and acetone (O. Hesse, *Amer. Jour. Pharm.*, 1885).

The following table exhibits the more noteworthy properties of the principal cinchona alkaloids, the table being that of Flückiger, in *Cinchona Barks*, p. 66:

- | | |
|--|--|
| (a) Hydrated crystals are formed by | Quinine, Quinidine. |
| Not containing water of crystallization..... | { Cinchonine, Cinchonidine,
Quinamine, Homoquinine. |
| (b) Abundantly soluble in ether | Quinine, Quinidine, Quinamine. |
| Slightly soluble in ether | Cinchonidine, Cinchonamine. |
| Very sparingly soluble in ether | Cinchonine. |
| (c) Levogyrate solutions afforded by | Quinine, Cinchonidine. |
| Dextrogyrate solutions afforded by | Quinidine, Cinchonine, Quinamine. |
| (d) Thalleioquin is afforded by | Quinine, Quinidine, Homoquinine. |
| Thalleioquin is not afforded by | Cinchonine, Cinchonidine, Quinamine. |
| (e) Fluorescence is displayed in the acid solu-
tions of salts of | { Quinine, Quinidine, Homoquinine. |
| No fluorescence is displayed by | Cinchonine, Cinchonidine, Quinamine. |

III. ACID AND OTHER CONSTITUENTS OF CINCHONA.—The cinchona alkaloids exist naturally in the bark in combination with one or more acids—*kinic*, *kinovic*, and *cinchotannic acids* being associated with them, forming *kinates* (*quinates*), *kinovates* (*quinovates*), and *cinchotannates*. These acids are minor principles so far as the medicinal value of the cinchonas is concerned.

KINIC ACID (*Quinic*, or *Cinchonic acid*) ($C_7H_{13}O_6$).—This is the *Chinasäure* of Hofmann, and is a principle closely related to quercite or acorn-sugar ($C_6H_7[OH]_5$). It was among the first observed of the cinchona constituents, its calcium compound having been obtained as early as 1745 by the Comte Claude Toussaint Marot de Lagaraye. Hermbstädt (1786), of Berlin, indicated the character of the compound, though he believed the acid to be tartaric, but the acid was identified and named, in 1790, by Friedrich Christian Hofmann, a Hanoverian chemist, of Leer. This body gives to the aqueous extracts of cinchona their acid character, being present in some barks to the extent of 9 per cent. Besides, it occurs in coffee beans, and in several species of *Vaccinium*, *e. g.*, the American cranberry (*E. Claassen*, 1890). It forms readily soluble, hard, and large monoclinic crystals, permanent in the air. The aqueous solution is without odor, and is purely sour and not bitter to the taste. Such a solution exerts a left-handed polarization. It is more soluble in water than in strong alcohol, but very little soluble in ether. At $162^\circ C$. ($323.6^\circ F$.) the crystals fuse. This acid is a benzol derivative, having the graphic formula $C_6H_7(OH)_4COOH$, which explains the possibility of its being reduced to benzoic (C_6H_5COOH) and protocatechuic acids ($C_6H_3(OH)_3COOH$) by means of heating with hydriodic acid. By more energetic oxidation, as when treated with sulphuric acid and manganese dioxide, it yields, besides formic acid and carbon dioxide, *kinone* (*quinone*) ($C_6H_4O_2$), a crystalline, bright-yellow sublimate. Its physiological effects are not pronounced.

KINOVIC ACID (*Quinovic*, or *Chinovic acid*) ($C_{24}H_{38}O_8$) is obtained from East India barks by extraction with dilute alkalies, precipitation with acid and purification of the precipitate. It was first obtained as a decomposition product of the glucosid *kinovin* (Hlasiwetz). It forms shining, white crystals, or a crystalline powder, not soluble in water or chloroform, sparingly soluble in cold alcohol and ether, more readily soluble in hot alcohol, and easily soluble in the solutions of alkaline carbonates and caustic alkalies. It is a feeble acid, and all its solutions are bitter. It is reputed tonic, a calcium compound seeming to have been preferred for its exhibition. Kinovic acid results from the action of hydrochloric acid upon an alcoholic solution of chinovin, whereby this substance is split into a smeary, uncrystallizable sugar, called *mannitan*, or *kinovic sugar* ($C_6H_{12}O_5$), and *kinovic acid* ($C_{24}H_{38}O_8$).

CINCHOTANNIC ACID (*Cinchotannin*, or *Quinotannic acid*) ($C_{24}H_{38}O_9$).—This is tannic acid, or tannin of cinchona, and the *soluble red coloring matter*, or *soluble cinchona-red* of Pelletier and Caventou. It has all the properties of tannin; it precipitates ferric solutions green (the red from the pale bark, however, precipitates these solutions brown). It also precipitates gelatin and tartar emetic, and forms a compound with starch, insoluble in the cold, but soluble above $50^\circ C$. ($122^\circ F$.). It exists in cinchona barks in amounts varying from 1 to 4 per cent.

De Vrij, in 1885, observed in one sample of *Cinchona officinalis*, the exceptionally high amount of 12 per cent (*Amer. Jour. Pharm.*).

When prepared from its lead salt it forms an acidulous non-bitter astringent and very hygroscopic mass of a bright yellowish color. It is soluble in water, ether, and alcohol. Heated to 100° C. (212° F.), cinchotannic acid turns dark-red, at the same time becoming insoluble in water. Its aqueous solution absorbs oxygen from the air, particularly if acids or alkalies have been added, and red products are formed. When boiled with diluted sulphuric acid it splits into cinchona-red and sugar (Rembold, 1867).

CINCHONA-RED, or *Insoluble cinchona-red* ($C_{20}H_{12}O_8$), is inodorous, insipid, reddish-brown, nearly insoluble in water and ether, readily soluble in alcohol and alkalies, does not precipitate gelatin, but does precipitate tartar emetic. It exists in some specimens of bark to the extent of 10 per cent, being most abundant in the thicker red barks. It is undoubtedly formed in the bark by the decomposition of cinchotannic acid. Fused with caustic potash it yields protocatechuic acid. An ammoniacal solution of cinchona-red yields, with alum, a red lake.

Besides the acid bodies, the following principles belong to this class of barks:

Chinovin (*Quinovin*, or *Kinovin*) ($C_{20}H_{12}O_8$).—This is an amorphous, bitter glucosid, found not only in the cinchonas, but in the nearest relatives among the *Rubiaceæ*, and is the body known as *cinchona-bitter*, *chinova-bitter*, or *kinovic-bitter*. It was first observed by Pelletier and Caventou, in 1821, in *Cinchona nova surinamensis*, and named *quinovic acid* ("acide quinovique") a name afterward corrected, and which properly belongs to the acid which has been considered above. Water hardly dissolves chinovin, but it is freely soluble in acetone, alcohol, ether, chloroform, and oils. It has no action upon litmus, yet, with the alkalies, it forms salts, most of which dissolve in water, the solutions being very bitter.

Kerner (1859-62) has applied the name *cinchocerotin* to a substance obtained by extracting cinchona with boiling alcohol, from which solution it separates on cooling. Purified, it displays handsome, pure white, crystalline laminae, of a neutral reaction, and fusible at 180° C. (266° F.). Its composition corresponds to the formula $C_{27}H_{34}O_4$. Fabbroni first separated the volatile oil, which is of a butyraceous consistence, and gives to cinchona barks their odor.

Tests and Quantitative Determination of Alkaloids in Cinchona Bark.—

As stated before, the *U. S. P.* demands that CINCHONA contain not less than 5 per cent of alkaloids, at least 2.5 per cent of which must be quinine. CINCHONA RUBRA is required to contain not less than 5 per cent of its peculiar alkaloids. The table on page 549, compiled mainly from data contained in Flückiger's *Cinchona Barks*, by Power, 1884 (marked in the table by *), demonstrates the amount of alkaloids in various species of cinchona barks.

Broughton found but little more than traces of alkaloid in the leaves of the Indian *Cinchona succirubra*. Happersberger (*Amer. Jour. Pharm.*, 1883, p. 197), from analyses of the leaves of several species of *Cinchona*, found those of the *C. Calisaya* to have a predominant amount of bases (2 per cent)—these alkaloids being quinine, quinidine, cinchonine, and cinchonidine, quinidine amounting to about one half of the total yield. These species were grown in an unfavorable locality in California. Therefore the leaves seem to deserve more recognition than has hitherto been given them.

TESTS FOR SPURIOUS BARKS.—As spurious barks, liable to be substituted, are found in commerce, it is of importance that some ready means for their detection should be known. Bitterness is not always characteristic of the value of cinchona bark; barks which do not contain traces of alkaloids, and yet contain considerable kinovic acid, are very bitter. An infusion of such barks will give, upon the addition of a solution of sulphate of copper, a greenish precipitate of kinovate of copper. Tannic acid has been recommended as the best reagent for distinguishing the genuine from the spurious barks, as it forms insoluble compounds (tannates) with the alkaloids of genuine Peruvian barks. In using this test, all that is necessary will be to make a decoction or infusion of the bark under examination, filter it, add a solution of tannic acid, when, should the bark contain any of these peculiar alkaloids, the addition of the solution of tannic acid will immediately cause a precipitate of them as tannates. Consequently those barks which yield no precipitate with tannic acid, are destitute of these alkaloids.

Mr. Grahe has also instituted the following ready process for distinguishing the true from the false barks. He finds that true cinchona barks, when submitted to dry distillation, give a product of a bright carmine color; this product is characteristic of these barks, and is not furnished by any others that do not contain the cinchona alkaloids. The quantity of this red substance depends upon the amount of the alkaloids, and it appears to afford a tolerable indication of this amount. This test is applied by heating the fragment of a bark, weighing about 5 or 10 grains, in an ordinary test-tube, gradually raising the heat to redness. With cinchona bark a whitish smoke is given off, and also watery vapor, which condenses upon the sides of the tube. Very shortly afterward, the red color begins to appear, communicating to the vapor a reddish tinge, and at about one inch distant from the heated portion of the tube there is deposited a red pulverulent film, which gradually passes into a thick oleaginous liquid, running down the glass in drops or streaks of a fine carmine color, in the water condensed with it. Close to this point are deposited the tarry products, generally resulting from the destructive distillation of vegetable substances. The presence of some substances prevents the production of this red color, even in the case of the true cinchona barks, such as caustic alkalies, lime, nitric and chromic acids, bichromate of potassium, glacial phosphoric acid, and sulphuric acid.

As regards the quantitative determination of the alkaloids contained in cinchona barks, numerous assay methods have been proposed (see for example that of Dr. J. F. L. Winckler, *American Dispensatory*, 15th edition). These methods have been appropriately classed by Husemann and Hilger (*Pflanzenstoffe*, 1884) into 3 groups, according to the agent employed in the abstraction or liberation of the alkaloids, and are thus distinguished as *Acid methods*, *Lime methods*, and *Ammonia methods*. For an account of De Vrij's process, which is a representative of the acid methods, see *Amer. Jour. Pharm.*, 1885, p. 627. The process of the *British Pharmacopœia*, and that indicated by Squibb (*Ephemeris*, Vol. I, p. 105, 1883), are methods employing lime, while those directed by the *German* and the *United States Pharmacopœias* employ ammonia. For an interesting comparative study of some recent methods, see L. F. Kebler, *Amer. Jour. Pharm.*, 1896, p. 79. The United States Pharmacopœial process is as follows:

ASSAY OF CINCHONA.—I. *For Total Alkaloids.*—"Cinchona, in No. 80 (or finer) powder, and completely dried at 100° C. (212° F.), twenty grammes (20 Gm.) [309 grs.], alcohol, ammonia water, chloroform, ether, normal sulphuric acid V.S., potassium hydrate V.S., each a sufficient quantity. To 20 Gm. of cinchona, in very fine powder, and contained in a bottle provided with an accurately ground glass stopper, add 200 Cc. of a previously prepared mixture of 19 volumes of alcohol, 5 volumes of chloroform, and 1 volume of ammonia water, stopper the bottle and shake it thoroughly and frequently during 4 hours. Then separate the liquid by pouring it into another bottle through a funnel containing a pellet of cotton, in such a manner that no material loss by evaporation may result. Transfer 100 Cc. of the clear filtrate (representing 10 Gm. of cinchona) to a beaker, and evaporate it to dryness. Dissolve the residue of crude alkaloids thus obtained in 10 Cc. of water and 4 Cc. of normal sulphuric acid, with the aid of a gentle heat, filter the cooled solution into a separatory funnel, and wash the beaker, and filter until the filtrate no longer has an acid reaction, using as small a quantity of water as possible. Now add 5 Cc. of potassium hydrate V.S., or such an amount as will render the liquid decidedly alkaline, and extract the alkaloids by shaking the mixture, first with 20 Cc., and then repeatedly with 10 Cc. of chloroform, until a drop of the last chloroform extraction, when evaporated on a watch-glass, no longer leaves a residue. Evaporate the united chloroformic extracts in a tared beaker, dry the residue at 100° C. (212° F.), and weigh. The weight found, multiplied by ten (10), will give the percentage of *total alkaloids* in the specimen of cinchona tested.

II. *For Quinine.*—"Transfer 50 Cc. of the clear filtrate remaining over from the preceding process (and representing 5 Gm. of cinchona) to a beaker, evaporate it to dryness, and proceed as directed in the assay for total alkaloids, using, however, only one-half the amounts of volumetric acid and alkali there directed. Add the united chloroformic extracts containing the alkaloids in solution, gradually, and in small portions at a time, to about 5 Gm. of powdered glass contained

in a porcelain capsule placed over a water-bath, so that, when the contents of the capsule are dry, all or nearly all of the dry alkaloids shall be in intimate admixture with the powdered glass, and the chloroform be completely expelled. Now moisten the residue with ether, and, having placed a funnel containing a filter of a diameter of 7 Cm., and well wetted with ether, over a small graduated tube (A), transfer to the filter the ether-moistened residue from the capsule. Rinse the latter several times, if necessary, with fresh ether, so as to transfer the whole of the residue to the filter, then percolate with ether added drop by drop, until exactly 10 Cc. of percolate have been obtained. Then collect another volume of 10 Cc., by similar, slow percolation with ether, in a second graduated tube (B). Transfer the contents of the two tubes completely (using ether for washing) to two small, tared capsules, properly marked (A and B) so as to avoid confusion, evaporate to a constant weight at 100° C. (212° F.), and weigh them. (The residue in A will contain practically all the quinine, together with a portion of the alkaloids less soluble in ether; the residue in B will consist almost entirely of these alkaloids). From the amount of residue obtained in capsule A deduct that contained in B, and multiply the remainder by twenty (20). The product will represent, approximately, the percentage of *quinine* (containing 1 molecule of water) in the specimen of cinchona tested.—(U. S. P.).

Action, Medical Uses, and Dosage.—Cinchona bark is tonic, antiperiodic, slightly astringent, and topically antiseptic. When swallowed, a sensation of warmth is experienced at the stomach, which gradually spreads over the whole trunk; occasionally, it produces an unpleasant excitement of the stomach and bowels, with retching and emesis, more especially if the former be sensitive. In a little while after its administration the general system becomes more or less influenced, the pulse being fuller and more rapid, and a gentle stimulus imparted to the various organs of the body. With many persons it occasions symptoms which have been termed *cinchonism*, and which, some believe, are evidences that the remedy is exerting a favorable influence; but these symptoms should never be pushed too far. They are: Throbbing headache, and giddiness, of greater or less severity, tinnitus aurium, and imperfect hearing. Cinchona is valuable in functional derangement of the stomach, improving digestion, and invigorating the nervous and muscular systems in diseases of general debility, and in convalescence from exhausting diseases. Cinchona will be found useful in all *febrile, eruptive, and inflammatory diseases*, which manifest a degree of periodicity, in which it should be administered during the remissions; it is also valuable during the low and *typhoid conditions* of these diseases, and also in those cases, where, from an excessive and continued secretion of pus, the system becomes very much enfeebled and prostrated, in which it supports the powers of the constitution until all abnormal action is removed. It is likewise of much benefit in all chronic affections attended with periodicity, great feebleness, or nocturnal perspiration. When it occasions vomiting, its use should be suspended for a time. Its employment is contraindicated in acute inflammation, inflammatory fever, plethora, active hemorrhages, and in all nervous or vascular irritations.

Cinchona bark, however, exhibits its most important therapeutical powers as an antiperiodic, and in the consequent influence it exerts in almost invariably curing *remittent and intermittent fevers*, and the generality of diseases which are accompanied by symptoms of marked periodicity, as *neuralgia, hemicrania, dyspepsia, diarrhoea, and dysentery*, when epidemic, etc. Its use should in most cases be preceded by a mild laxative, after the action of which the powder may be given in doses of 10 to 60 grains, and repeated, according to circumstances, every 1, 2, or 4 hours, until 1 or 2 ounces have been taken during the periods of intermission, and continue thus until a cure is effected, or the remedy is found insufficient for the cure of the disease. In the use of the barks, to obtain their antiperiodic influence, the red and yellow are considered superior to the pale, and of which the red is preferred. As a tonic, the pale bark is generally preferred, being less obnoxious to the stomach and intestines. Quinine, or its salts (see *Quinine Sulphas*), especially the sulphate, is usually employed as a tonic and antiperiodic in place of the bark itself, but there have been many instances in which the bark in powder has succeeded in effecting a cure, when its alkaloidal salts failed; the cause of this is not well understood. Still, it is often the case that the crude drug, which holds

all associated principles, is more effective than its isolated alkaloids. In such cases, when the powder, from its bulk, or otherwise, offends the stomach, the infusion, decoction, tincture, or extract may be administered. Sometimes cinchona, or its preparations, occasion purging, which may be obviated by small portions of opium or laudanum. When a tonic effect only is desired, and periodicity is lacking, or when a tonic is indicated after *exhaustive bleeding*, the bark is preferable to the quinine salts, and, for some reason not well determined, the bark is sometimes preferable in chronic cases of *ague*. Cinchona is to be preferred when an astringent effect is desired.

Externally, a poultice of the bark has been found an excellent application to *felons*, *fetid* and *gangrenous ulcers*, etc.; also as an injection with opium, when the stomach rejects it; the powdered bark, placed between muslin, and held in place by sewing it in cross-bars, the same as in quilting, making medicated jackets, to be worn in contact with the body, has been of utility in *obstinate intermittents*. Dose of cinchona as an antiperiodic, from $\frac{1}{2}$ to 1 drachm; as a tonic, from 10 to 60 grains; of the infusion or decoction, 2 fluid ounces, to be repeated 2 or 3 times a day; of the extract, from 5 to 30 grains; of the fluid extract, 10 to 60 drops; of specific cinchona, 5 to 30 drops.

Quinine, cinchonine, and quinidine appear to possess somewhat similar medicinal properties; their salts (as the sulphate) appear to be best adapted for medicinal use, principally on account of their ready solubility. Dose of either, from 1 to 5 grains, 3 times a day, or oftener, if required; in severe *intermittents* as high as 10 grains may be administered for a dose.

Specific Indications and Uses.—Periodicity and, like quinine, effective when the pulse is soft and open, the tongue moist and cleaning, the skin soft and moist, and the nervous system free from irritation. If opposite conditions prevail, cinchona will be likely to aggravate. *Empyema*; gastric debility; anemia and debility from chronic suppuration; afternoon febrile conditions; weakness, with pale surface, loss of appetite, feeble digestion, and deficient recuperative powers.

Related Barks.—*FLAT CALISAYA*, scarcely ever met in American markets, occurs in pieces from 8 to 15 inches in length, from 1 to 3 inches broad, and from 1 to 5 lines in thickness. It is but slightly curled, generally uncoated. It has considerable density, is perfectly uniform in texture, marked on its outer surface by longitudinal digital furrows, more or less running into one another, and separated by projecting ridges. Its external surface is of a somewhat brownish tawny-yellow, often with blackish-red patches; its internal surface is fibrous, of a yellowish-tawny color, sometimes—especially when the bark is fresh—with an orange tint, and often with an undulating grain. The transverse fracture is fibrous, the fibers being short, easily detached, and irritating the skin like the hairs of *Dolichos pruriens*. The longitudinal fracture is not splintery, and presents a surface covered with brilliant points, owing to the reflection of light from the denuded fibers, and is of a uniform color. The taste is very bitter, the bitterness being gradually developed by mastication, with scarcely any astringency.

The great reputation of the calisaya bark has made it so much sought after, that it was becoming exceedingly rare, and there is no doubt that it might have one day disappeared almost entirely from commerce, and that we should be obliged, ultimately, to be satisfied with one or other of the species judged of less value. Cultivation has, however, removed the possibility of its extinction. In this connection, *Amer. Jour. Pharm.*, 1896, p. 120, remarks that the species *C. Ledgeriana*, cultivated in Java, now yields a surplus of quinine. Weddell says that the increasing scarcity of calisaya bark induced the *cascarilleros* constantly to mix the barks of several of their Cinchonas, and this fraud was effected much more successfully than it was formerly, and, without much experience, it was sometimes difficult of detection. The admixture was made especially with the barks of *Cinchona Boliviana* and *Cinchona ovata* var. *rufinervis*; or, more rarely, and only on the coast, with the bark of *C. scrobiculata*; in other words, with the barks which M. Guibourt calls, with much justice, the *light calisayas of commerce*. With the bark of *scrobiculata* it would not be likely to be long confounded, but it may readily be so with the first two; so much is this the case that in Bolivia the bark of *C. Boliviana* is also called *Calisaya bark*, a name which its properties will, at any rate, justify. The *best characters* by which to distinguish the true (flat) calisaya from all other species, are, the shortness of the fibers which entirely cover the surface of its transverse fracture, and the facility with which these are detached, instead of remaining adherent and pliant, as in the case with the *rufinervis* and *scrobiculata*. Lastly, its uniform rufous color, and its not being marbled throughout its thickness with white, sufficiently distinguish it from the bark of *C. Boliviana*. Added to these characters, its great density, the depth of the furrows and the projecting edges, are generally sufficient to distinguish the flat calisaya from all other barks with which it may be mixed. Rolled calisaya is much more difficult to distinguish, for not only does its peridermis, in its physical character, much resemble that of many other species, especially that of *scrobiculata* and *rufinervis*, but the fracture does not present clear characters as it does in older barks. If even a microscope be used in the examination, the characters are very slight.

Spurious Cinchona Barks.—Previous to the discovery of the alkaloids, various barks entered commerce either as adulterants or substitutes for cinchona barks. Since the alkaloids have become so well known, these false barks, which anatomically differ from the true cinchonas, as well as being very inferior in value, have been designated *spurious cinchona barks*. They seldom now appear in commerce. They were derived chiefly from the genera, *Cascarilla*, *Ladenbergia*, *Ercastemma*, and *Nauclea*. The bast fibers of those barks closest related to cinchona exhibit central cavities—the so-called sieve-like fibers. Grahe's test is regarded as sufficient to distinguish most of these barks from the true cinchonas.

CUPREA BARK is the most important of the spurious barks now recognized. It does not enter into general commerce, but is abundantly used in the manufacture of quinine. The name *cuprea* was given it by Flöckiger, in 1871, on account of its peculiar rusty copper color. It comes from the central and southern sections of Colombia, along the eastern Andes. The *Remijia Purdieana*, Weddell, and *Remijia pedunculata*, Triana (*Cinchona pedunculata*, Karsten), are pointed out by Triana (1882) as the source of that from the first-named locality. The bulk of these barks comes in small fragments, though some of it occurs in flattish or channelled pieces, and, occasionally, in quills about 20 inches long, and from less to $\frac{1}{4}$ inch in thickness. The corrugated, or warty, light-brown cork is removed, so that the scraped, smooth surface often shows sharply incised impressions, made with a sharp knife, thus showing the characteristic copper color of the outer bark tissue. It is much harder than the true cinchona, is heavy, and sinks in water. That from south Colombia is more compact, denser, and exhibits a conchoidal fracture. By Grahe's test it yields the red tar, like the cinchonas. The total alkaloids average about 3 per cent, 2 per cent of which is quinine, cinchonine and quinidine being the remainder. According to Hesse, Howard, and others, cinchonidine is not present. The south Colombian cuprea barks contain cinchonamine.

FRAUDULENT RED CINCHONA BARKS are produced by acting upon inferior barks with ammonia, thereby producing cinchona-red. Their red aqueous preparations precipitate brown-red with Nessler's reagent, instead of white, as with good or normal cinchona barks.

OTHER CINCHONA BARKS.—A number of unofficial barks have been known from time to time. A number of them are given in the *Compendium* under Cinchona.

Crossopteryx febrifuga, Benth (Nat. Ord.—Rubiaceæ). Africa. This bark is febrifuge, and yields (Hesse) *crossopteryxin*, a white, non-crystalline alkaloid soluble in alcohol, ammonia, and ether. A blue fluorescence marks its infusion, which disappears in the presence of sulphuric acid, and is restored by an alkali, even after the infusion has been boiled.

Pinckneya pubescens, Michaux (*Cinchona caroliniana*, Biret).—Yields *Georgia bark*, a febrifuge and tonic. Swamps from South Carolina to Florida. Cinchonine (?) is said by Farr to be present in the bark.

Other Febrifuges.—**CHINA MORADA**, *Quina morada*. The bark of *Pogonobus febrifugus* (Nat. Ord.—Rubiaceæ), and several other Bolivian and Argentine Republic trees. The former contains a fluorescent (blue) body, *moradin*, and an alkaloid, *moradine*. Therapy, the same as Cinchona.

PANBOTANO BARK.—Root of *Calliandra Houstoni* (Leguminosæ). Mexico. A tincture of 2 ounces of the root taken in 4 doses in a day, is highly praised as an antiperiodic (Valude).

Gurruya Fremontii, California fever-bush, Skunk-bush.—The intensely bitter leaves of this California shrub are provincially used as an antiperiodic and tonic. The alkaloid, *garryine*, was announced by D. W. Ross (*Amer. Jour. Pharm.*, 1877). Dose of fluid extract, 10 to 30 drops.

CINCHONIDINÆ SULPHAS (U. S. P.)—CINCHONIDINE SULPHATE.

FORMULA: $(C_{19}H_{21}N_3O)_2HSO_4 + 3H_2O$. **MOLECULAR WEIGHT:** 738.52.

"The neutral sulphate of an alkaloid obtained from the bark of various species of Cinchona"—(U. S. P.).

History and Preparation.—The base, *cinchonidine*, is contained chiefly in the cultivated India species, *Cinchona officinalis*, Hooker, and *Cinchona succirubra*, Pavon (Hesse); also in the South American species, *Cinchona tucujensis*, Karsten, and *Cinchona lancifolia*, Mutis. It was discovered by Winckler, in 1848, in the Maracaibo bark and a certain other species, and named by him *chinidin* (*quinidin*). Pasteur, having established, in 1853, that it was different from the base now known as quinidin, and isomeric with that known as cinchonin, gave it the name *cinchonidine*, which was not generally adopted until recently. Its formula was established by O. Hesse, who also found it associated with small amounts of *homacinchonidine* ($C_{19}H_{21}N_3O$), a substance which he found to be preponderate over cinchonidine, in some parcels of South American origin.

At one time the chinoidine of commerce (a mixture of cinchona bases), yielded a considerable amount of this base. It is now prepared, however, from the mother liquors obtained in preparing quinine sulphate (see table showing the amount of cinchonidine in various commercial samples of quinine sulphate by A. J. Cownley (*Amer. Jour. Pharm.*, 1886).

Description.—The alkaloid cinchonidine forms light, white, pulverulent, crystallizable masses. Sparingly soluble in cold (1680 parts), and more soluble in hot water. Alcohol (20 parts), and ether (70 parts) also dissolve it. At 206.5° C. (404° F.) it melts, and on cooling to 190° C. (374° F.) it congeals to a crystalline mass. Neutral solutions of its salts yield with Rochelle salt a crystalline precipitate insoluble in the excess of the precipitating liquid. The official body is the sulphate of the preceding alkaloid. It occurs in "white, silky, acicular crystals, without odor, and having a very bitter taste; slightly efflorescent on exposure to air. Soluble at 15° C. (59° F.), in 70 parts of water, and in 66 parts of alcohol; in 1.42 parts of boiling water, and in 8 parts of boiling alcohol. Also soluble in 1316 parts of chloroform, and almost insoluble in ether. The presence of sulphates of other cinchona alkaloids increases its solubility in ether and chloroform. At 100° C. (212° F.) the salt gives off its water of crystallization. At 215° C. (419° F.) it melts, and when ignited, it is consumed without leaving a residue. The salt is neutral, or has a faintly alkaline reaction on litmus paper"—(U. S. P.).

When treated with potassium sulphocyanate, either star-shaped groups of feathery, microscopic crystals, or stellate or fan-shaped groups of long, unbranched needles form. When the reagent is employed in excess, precipitation is so complete as not to cause even a turbidity when the filtrate is treated with ammonia. *Cinchotenidine* ($C_{18}H_{22}N_2O_2 \cdot 3H_2O$) is formed in colorless, prismatic crystals when cinchonidine is acted upon by potassium permanganate. The same occurs with the isomer, homocinchonidine sulphate (regarded as impure cinchonidine by Skraup and Claus), which forms either in fine, white needles, or in whitish prisms. This body dissolves in 70 parts of slightly warmed water. Its saturated solution in water prepared at 50° C. (122° F.), congeals to a gelatinous, crystalline mass holding mother-liquor, from which it is not easily separable. Under like treatment cinchonine sulphate forms smooth, shining needles easily drained of their mother-liquor. Beautiful prismatic crystals (with $2H_2O$), are only produced when cinchonidine sulphate is crystallized from alcohol. If crystallized from water, according to the amount of salt and degree of concentration, the result will be either fine, silky, lustrous needles, like the official salt, or shining, square crystals, devoid of color.

Tests.—"On adding ammonia water to the aqueous solution of the salt, a white precipitate (cinchonidine) is produced, which is but slightly soluble in ammonia, but dissolves in about 75 parts of ether. If concentrated sulphuric acid be added to a small quantity of the salt, not more than a faintly yellowish color should be developed (limit of readily carbonizable, organic impurities). Upon adding to this liquid a crystal of potassium dichromate, a yellowish-green color is produced, which gradually changes to grass-green. Addition of barium chloride T.S. to an aqueous solution of the salt produces a white precipitate insoluble in hydrochloric acid. A solution of the salt (about 1 in 1000) in diluted sulphuric acid should not exhibit more than a faint blue fluorescence (absence of more than traces of the sulphates of quinine or quinidine). If 1 Gm. of the salt be dried at 100° C. (212° F.), until it ceases to lose weight, the residue, cooled in a desiccator, should weigh not less than 0.920 Gm. (absence of an undue amount of water). If 0.5 Gm. of the salt be macerated with frequent agitation, at the ordinary temperature, with 20 Cc. of water, 0.5 Gm. of potassium sodium tartrate then added, the maceration continued, under repeated agitation for 1 hour at 15° C. (59° F.), and the mixture then filtered, the addition of 1 drop of ammonia water to the filtrate should not produce more than a slight turbidity (absence of more than small proportions of the sulphates of cinchonine or quinidine)"—(U. S. P.).

Action, Medical Uses, and Dosage.—This salt has been used as a substitute for quinine sulphate. When pure it is probably equally as efficient both as a prophylactic and remedial agent, during the prevalence of *malarial disorders*, as *intermittent* and *remittent fevers* and *miasmatic neuralgias*. It reduces the temperature even more readily than the quinine salt, and is a better tonic. It is claimed that it is not so likely to produce the unpleasant head symptoms often resulting from the use of quinine sulphate, and is pleasanter to take. Larger doses are required than of the latter salt. It may be given in doses of from 10 to 20 grains several hours before the expected chill; or where the paroxysms are mild, broken doses, 10 grains in all, may be given in the course of a day.

Specific Indications and Uses.—Periodicity, when the pulse is open and soft, the skin soft and moist, and nervous irritation absent.

Related Salts.—CINCHONIDINE HYDROBROMIDE has been administered hypodermatically (4 grains, twice a day) in malarial disorders, inflammations, and in the summer diseases of children.

CINCHONIDINÆ SALICYLAS, *Salicylate of cinchonidine* ($C_{20}H_{22}N_2O_7$). Needles sparingly soluble in water. Antiperiodic and antirheumatic. Dose, 15 to 20 grains in pill form as a daily allowance.

CINCHONINA (U. S. P.)—CINCHONINE.

FORMULA: ($C_{20}H_{22}N_2O$). MOLECULAR WEIGHT: 293.41.

"An alkaloid obtained from the bark of various species of *Cinchona*"—(U. S. P.).

History and Preparation.—Pelletier and Caventou, in 1820, discovered the alkaloidal nature of this principle, which had been observed before and named by Gomez (see *Cinchona alkaloids*). Most of the cinchonas yield it, the pale bark furnishing it most abundantly. According to a former Parisian Codex, cinchonine may be obtained by exhausting 125 parts of powdered pale bark, by 3 successive boilings with $2\frac{3}{4}$ parts of hydrochloric acid, and 500 parts of water, successively (so that 8 parts of acid and 1500 parts of water will be employed in the three boilings). Mix the decoctions, and then add $12\frac{1}{2}$ parts of quicklime diffused in water, and when precipitation is completed wash and dry the precipitate. Dissolve this in boiling alcohol, filter the solution while hot, distill in a water-bath, evaporate to dryness, digest in cold alcohol, and then dissolve the residue in boiling alcohol, with the addition of some animal charcoal; again filter while hot, and allow the cinchonine to crystallize spontaneously on the cooling of the liquid (*Par. Cod.*). Cinchonine may best be made from the mother-waters after sulphate of quinine has been prepared; the process is to considerably dilute the mother-waters with water, and then add ammonia; the precipitate thus formed is collected on a filter, washed, dried, and manipulated in the same manner cited.

The sulphate, acetate, hydrochlorate, etc., of cinchonine are made by dissolving cinchonine in the required diluted acid, filtering, evaporating, and crystallizing.

Description.—Cinchonine or cinchonina crystallizes readily in anhydrous, quadrilateral prisms bounded by oblique facets. It is a strong base, combining readily with acids. Cinchonine may be obtained by precipitating its salts with aqua ammoniæ, in which it is almost insoluble; it crystallizes readily from alcohol. The salts of cinchonine are bitter, and bear considerable analogy to those of quinine. The solution of cinchonine sulphate, however, when pure, is not fluorescent, and, unlike quinine, does not give the thalleioquin reaction. An alcoholic, or acidulated aqueous solution of cinchonine possesses the property of right-hand rotatory polarization. The formula of cinchonine was found by Laurent to be $C_{20}H_{22}N_2O$, which was confirmed by Skraup, and is now accepted by the U. S. P. in preference to the old formula of Pasteur ($C_{20}H_{24}N_2O$). The U. S. P. describes cinchonine as occurring in "white, lustrous prisms or needles, without odor, at first almost tasteless, but soon developing a bitter after-taste; permanent in the air. Soluble at $15^{\circ}C$. ($59^{\circ}F$.), in 3760 parts of water, and in 116 parts of alcohol; in 3500 parts of boiling water, and in 26.5 parts of boiling alcohol. Also soluble in 526 parts of ether, and in 163 parts of chloroform. At $240^{\circ}C$. ($464^{\circ}F$.), the crystals fuse together, and at $258^{\circ}C$. ($496.4^{\circ}F$.), they melt, forming a brown liquid. When ignited, they are consumed without leaving a residue. When placed on moistened red litmus paper, cinchonine shows an alkaline reaction"—(U. S. P.). Cinchonine sublimes without undergoing change, forming large crystals when heated in a current of an indifferent gas, e. g., hydrogen (Husemann and Hilger), sublimation beginning at $220^{\circ}C$. ($428^{\circ}F$.) (Hesse). Sulphuric acid in excess in the presence of heat, renders cinchonine amorphous (Winckler). Cinchonine, though permanent in the air, will absorb sufficient carbon dioxide in the atmosphere to cause it to feebly effervesce when treated with acids. Cinchonine or any of its salts are soluble in chlorine water without being decomposed. Such a solution precipitates white with ammonia (compare thalleioquin test under *Quinine*). Of its salts, the oxalate, gallate, and neutral tartrate are soluble in hot

water, acids (in excess), and alcohol, but not in cold water, while the latter dissolves the acetate, hydrochlorate, nitrate, phosphate, and sulphate of cinchonine.

Distilled with caustic potash *quinoline* is produced (Gerhardt), together with pyridine and its homologues. Oxidation of the alkaloid or its salts with potassium permanganate yields, besides formic acid, *cinchotenine* ($C_{18}H_{21}N_3O_8 + 3H_2O$), a neutral body, and an alkaloid, *hydrocinchonine* ($C_{18}H_{21}N_3O$). Cinchotenine may also be obtained by oxidation of cinchonine or its salts with plumbum dioxide and sulphuric acid. Further action of potassium permanganate and other oxidizing agents upon cinchonine results in the formation of acids, these being quinoline and pyridine derivatives, *e. g.*, *quinoline-carbonic acid* (*cinchoninic acid*) ($C_9H_7N.COOH$), and the pyridine derivative *pyridine-dicarbonic acid* (*cinchomeronic acid*) ($C_5H_5N.[COOH]_2$) (Weidel). *Cinchene* ($C_{19}H_{21}N_3$), a volatile, crystallizable base, is formed when alcoholic potassa and cinchonine chloride are boiled together (Koenigs, 1881). By exposing to a heat of $130^\circ C.$ ($266^\circ F.$), a mixture of absolute alcohol, caustic soda, and cinchonine, a permanent, oily base having the composition $C_{20}H_{25}N_3$, was obtained by Michael in 1886. The commercial cinchonine was found to contain *cinchotine* (of Skraup) ($C_{18}H_{21}N_3O$), the hydrocinchonine of Caventon and Willms.

Tests.—"On adding to a neutral or not more than faintly acid solution of cinchonine, or any of its salts, enough potassium ferrocyanide T.S. to redissolve the precipitate first formed, and afterward an acid, a golden-yellow precipitate will be formed, which, when redissolved by gently warming the liquid, will separate, on cooling, in minute scales or needles. On adding an excess of ammonia water to a solution of cinchonine in a dilute acid, the alkaloid will be precipitated. The precipitate is but feebly soluble in ammonia and should require not less than 300 parts of ether for solution. A solution of cinchonine (1 in 1000) in diluted sulphuric acid should not exhibit more than a faint blue fluorescence (absence of more than traces of quinine or quinidine). Cinchonine should not impart more than a faintly yellowish tinge to concentrated sulphuric acid (limit of readily carbonizable organic impurities)" —(U. S. P.).

Action and Medical Uses.—(See *Cinchoninæ Sulphas*).

CINCHONINÆ SULPHAS (U. S. P.)—CINCHONINE SULPHATE.

FORMULA: $(C_{19}H_{21}N_3O).H_2SO_4 + 2H_2O$. **MOLECULAR WEIGHT:** 720.56.

SYNONYM: *Cinchoniz sulphas* (U. S. P., 1870).

Preparation.—The process of the U. S. P. (1870) is essentially as follows: Render the mother-liquor obtained in the preparation of quinine sulphate alkaline by adding gradually, with continued stirring, a sufficient quantity of solution of soda. Collect the precipitate which falls, place it on a filter and wash it with water (to remove sodium sulphate) and dry it. Next wash it with alcohol in successive portions to remove other alkaloids which may be present and soluble in that medium. Add to the residue 8 times its weight of water, heat the mixture, and add gradually sulphuric acid until saturation is effected, and the mixture becomes clear. Boil the liquid with animal charcoal (*unpurified*), filter while yet hot, and set aside, that crystals may form. Drain the crystals and dry them on paper. By further treatment of the mother-liquid (concentration), more crystals may be obtained.

Winckler has shown that an excess of sulphuric acid in the presence of heat renders cinchonine amorphous; therefore care should be had that the acid be not in excess. This is obviated to an extent by employing animal charcoal which has not been purified (bone black), the calcium carbonate present tending to neutralize the free acid.

Description and Tests.—Cinchonine forms two sulphates, the acid sulphate (see *Related Compounds*), and the neutral sulphate, or the official salt. It forms "hard, white, lustrous, prismatic crystals, without odor, and having a very bitter taste; permanent in the air. Soluble at $15^\circ C.$ ($59^\circ F.$), in 66 parts of water, and in 10 parts of alcohol; in 13.59 parts of boiling water and in 3.25 parts of boiling alcohol. Also soluble in 78 parts of chloroform, but almost insoluble in ether. At $100^\circ C.$ ($212^\circ F.$) it gives off its water of crystallization, and at $215^\circ C.$ ($419^\circ F.$)

it melts, forming a brown liquid. When ignited, it is consumed without leaving a residue. The salt is neutral to litmus paper. Addition of ammonia to an aqueous solution of the salt produces a white precipitate which should respond to the reactions and tests given under *Cinchonina*. On adding barium chloride T.S. to an aqueous solution of the salt, a white precipitate is produced, which is insoluble in hydrochloric acid. A solution of the salt (1 in 1000) in diluted sulphuric acid should not exhibit more than a faint blue fluorescence (limit of quinine or quinidine). If 1 Gm. of the salt be dried at 100° C. (212° F.), until it ceases to lose weight, the residue, cooled in a desiccator, should weigh not less than 0.95 Gm. (absence of an undue amount of water). If 1 part of the salt, reduced to powder, be macerated with frequent agitation, at the ordinary temperature with 80 parts of chloroform, it should wholly or almost wholly, dissolve (limit of quinine or cinchonidine). The salt should not impart more than a faintly yellowish tinge to concentrated sulphuric acid (limit of readily carbonizable, organic impurities" (U. S. P.).

Benzene and benzin do not dissolve this salt, but acids freely effect its solution. The solutions of cinchonine sulphate are very bitter, and are not fluorescent. If a drop of the saturated solution in water be placed in the field of the microscope, and a drop of potassium sulphocyanate solution be added, long, branched, radiating, anther-like crystals will be seen to form. Like cinchonine, the commercial sulphate yields *cinchotine* (Caventou and Willm's *hydrocinchonine*) ($C_{19}H_{21}N_3O$), which dissolves in alcohol more easily than cinchonine. Cold permanganate of potassium solution does not affect it, and its sulphate forms sharp, acicular crystals. It is separated from cinchonine by precipitating it fractionally. Cinchonine sulphate contains 82.8 per cent of base.

Action, Medical Uses, and Dosage.—In the main, the physiological action of cinchonine and its sulphate agrees closely with that of quinine. It is said, however, to be more poisonous to dogs and frogs than quinine sulphate. As an antiperiodic, it may be used where the patient can not take the quinine salt, though the dose must be larger than that of the latter, and, according to some, it is a less reliable agent. Its advantages over quinine are its cheapness, its greater solubility, its pleasanter taste, and its freedom from producing the gastric and head symptoms (tinnitus and disordered vision) of the latter, while, on the other hand, it is charged with producing a peculiar frontal oppression and pain, besides muscular debility, faintness, tendon-jerking, and pain in the region of the heart. The dose should be at least a third larger than that of quinine sulphate. Dose of cinchonine sulphate, as a tonic, from 1 to 2 grains; as an antiperiodic, 5 to 10 grains, about 3 doses generally being sufficient to prevent the recurrence of the chill.

Specific Indications and Uses.—Periodicity, when the pulse is open and soft, the skin moist and soft, and nervous irritation absent.

Related Compounds.—**ACID CINCHONINE SULPHATE** ($C_{19}H_{21}N_3O.H,SO_4.3H_2O$). This salt is prepared by adding diluted sulphuric acid to the neutral sulphate, and crystallizing. It forms rhombic-octahedral crystals containing 59.2 per cent of the base; soluble in less than one-half part of water and in alcohol 90 parts; insoluble in ether. It becomes opaque when exposed to dry air.

CINCHONINE HYDROCHLORIDE ($C_{19}H_{21}N_3O.HCl.2H_2O$).—Prepared in crystals resembling quinine sulphate by adding cinchonine in excess to diluted hydrochloric acid. Soluble in boiling water (1 in 3.2), and in cold water (1 in 24), chloroform (1 in 22.2), alcohol (1 in 1.3 of 80 per cent), and ether (1 in 273.) It contains 80.24 per cent of base, and melts near 130° C. (266° F.). It does not fluoresce in solution like quinine sulphate, and forms with silver nitrate a white precipitate. It may thus be distinguished from the latter salt, for which it is sometimes substituted, or used in adulterating.

CINNAMOMUM.—CINNAMON.

The barks of numerous species of *Cinnamomum*.

Nat. Ord.—Laurinæ.

Three kinds of cinnamon are official in the U. S. P., viz.:

I. **CINNAMOMUM CASSIA** (U. S. P.), *Cassia cinnamon* (*Cinnamomum* of U. S. P., 1880), *Cassia bark*. "The bark of the shoots of one or more undetermined species of *Cinnamomum* grown in China (*Chinese cinnamon*)"—(U. S. P.).

II. *CINNAMOMUM SAIGONICUM* (U. S. P.), *Saigon cinnamon*.—"The bark of an undetermined species of *Cinnamomum*"—(U. S. P.).

III. *CINNAMOMUM ZEYLANICUM* (U. S. P.), *Ceylon cinnamon* (*Cinnamomum*, U. S. P., 1880). "The inner bark of the shoots of *Cinnamomum zeylanicum*, Breyne"—(U. S. P.). (*Laurus Cinnamomum*, Linné).

COMMON NAMES: I. *Cassia cinnamon*, *Cassia bark*, *Chinese cinnamon*, *Cassia lignea*.

II. *Saigon cinnamon*.

III. *Ceylon cinnamon*, *Cinnamon bark*.

ILLUSTRATION: *Cinnamomum zeylanicum*, Bentley and Trimen, *Med. Plants*, 224.

Botanical Source and History.—The trees yielding cassia or Chinese cinnamon are of several undetermined species cultivated in China and India. Accord-

Fig. 74.

Branch and bark of Cinnamon plant.

ing to Charles Ford (*Jour. Linn. Soc.*, 1882), the *Cinnamomum Cassia* of Blume yields the true cassia bark of the Chinese. Many other species have been thought, however, to yield a portion of this bark. Chinese cinnamon proper is the product of a wild tree growing in Annam, and should not be confused with cassia cinnamon. It never occurs in our commerce, being consumed entirely in China, to which country it is exported. The cassia barks from Sumatra and Java, the latter being of excellent quality, are said to be the products of *Cinnamomum Cassia*, Blume, and *Cinnamomum Burmanni*, Blume. Indian cassia is derived in part, at least, from several species of India, which are by many botanists considered but varieties of the Ceylon cinnamon tree. They are the *Cinnamomum Tamala*, *C. nitidum*, and *C. iners*. *Cinnamomum Burmanni* var. *Kiamis* yields *Massoy-bark*. The botanical source of Saigon cinnamon is unknown. In fact the source of the species yielding cassia bark is but little known,

excepting that of the Ceylonese bark.

Cassia bark does not come in commerce with the quills telescoped (in the form of quills within quills) like the Ceylon bark. They are usually single, though sometimes double, and are tied together in bundles with bamboo. It is gathered from March to May from trees of about the sixth year's growth. The branches after being cut, are carried to a building where the shoots, after being deprived of leaves and twigs, are twice cut longitudinally through the bark, after which cross-incisions are made at intervals of about 16 inches. The bark is then detached by a curved horn-knife, and while still pliable is laid inner surface downward, and the epidermis detached with a plane. It is then dried for a day, and tied in bundles of about the diameter of the length of the pieces (Ford).

Cassia cinnamon is, in fact, a mixture of a variety of different qualities of cinnamon. It is generally met with in cylindrical rolls or quills of various sizes, from 2 to 12 lines in diameter, or in semi-tubular segments, 12 to 18 inches long, with the external layer much thicker than that of cinnamon; externally more of a dark red, traversed with thicker and more shining, straight or serpentine veins; more fibrous and paler in fracture; internal layer coarsely fibrous; heavier and more compact, with an odor similar to that of cinnamon, but not so strong or agreeable, and a corresponding taste more acrid, burning, and lasting, and at the same time mucilaginous. It is used in tinctures instead of cinnamon, and is the kind usually sold as cinnamon.

Saigon cinnamon comes in unscraped pieces or quills. *Java cinnamon* may resemble the Ceylon variety, though its flavor is not considered so fine; or it may resemble the better grades of cassia cinnamon, though its flavor is of a better quality. *Cayenne cinnamon* is somewhat mucilaginous, and is of a reddish hue.

Cinnamomum zeylanicum, Breyne (*Laurus Cinnamomum*, Linné).—This tree has a rough bark, and grows from 15 to 25 feet or more high, having a trunk from 1 to 1½ feet in diameter. Its branches are somewhat 4-cornered, and smooth; the leaves are ovate, or ovate-oblong, from 6 to 9 inches long, 2 or 3 inches broad, tapering into an obtuse point, triple-nerved, reticulated on the under side, smooth, with the uppermost the smallest, opposite, and coriaceous. Its flowers are small, hoary, silky, and white; the segments oblong and deciduous in the middle; the panicles are terminal and axillary, and stalked (L.—Ed.—P.).

Cinnamomum zeylanicum is a native of Ceylon, Sumatra, Borneo, etc., and is cultivated in many parts of both the new and old world. The bark is the official part; it has the odor peculiar to cinnamon, and an agreeable, warm, aromatic flavor, with a mild degree of sweetness. The leaves are similar in taste and odor, but less powerful, and contain a volatile oil, which may be procured by distillation. The odor of the flowers is to most people disagreeable, like newly-sawn bones (*Ed.*). The tree throws out no fragrance beyond its immediate sphere. The bark is the true cinnamon of commerce. It is usually collected from trees about 9 years old. The plant is kept pruned in such a manner that the shrub forms "stools," and from these a few shoots are produced, which, when about 2 years old, or just as the corky layer begins to appear (the bark beginning to change to a brown color), are cut, deprived of their leaves, and prepared for market. The peeling of the shoots and branches commences in May, and continues until the latter part of October. The bark is freed from its epidermis, and then dried, first in the shade, and afterward under exposure to the sun; it curls in drying into quills, which are subsequently placed within each other, as they will admit. The best bark comes from Ceylon, and is in the form of rolls about $\frac{1}{2}$ inch in diameter, and from 30 to 40 inches long, and composed of many quills within each other. The fragments of bark obtained in preparing the shoots are sold in the market as *cinnamon chips*. Cinnamon quills have a light-yellow color, and are thin, smooth, shining, a little thicker than cartridge paper, and break readily with a splintery fracture, being easily pulverizable. They possess a rich, pure, peculiar odor, and a warm, spicy, sweetish, and agreeable taste, and yield their virtues to water, but more readily to alcohol or spirits. A small amount of volatile oil may be procured from it by distillation. The thick, dark-brown, and feebly-flavored bark is of an inferior quality. Cinnamon is often adulterated with the poorer sorts, and likewise with the bark after having been deprived of its oil.

Description.—The following are the Pharmacopœial descriptions of the three varieties of cinnamon:

I. *CINNAMOMUM CASSIA* (*U. S. P.*), *Cassia cinnamon*.—"In quills of varying length and about 1 Mm. ($\frac{1}{16}$ inch) or more in thickness; nearly deprived of the corky layer; yellowish-brown; outer surface somewhat rough; fracture nearly smooth; odor fragrant; taste sweet, and warmly aromatic"—(*U. S. P.*).

II. *CINNAMOMUM SAIGONICUM* (*U. S. P.*), *Saigon cinnamon*.—"In quills about 15 Cm. (6 inches) long, and 10 to 15 Mm. ($\frac{3}{8}$ to $\frac{1}{2}$ inch) in diameter, the bark 2 or 3 Mm. ($\frac{1}{16}$ to $\frac{1}{8}$ inch) thick; outer surface gray or light grayish-brown, with whitish patches, more or less rough from numerous warts and some transverse ridges and fine longitudinal wrinkles; the inner surface cinnamon-brown or dark-brown, granular, and slightly striate; fracture short, granular, in the outer layer cinnamon-colored, having near the cork numerous whitish striæ forming an almost uninterrupted line; odor fragrant; taste sweet, warmly aromatic, somewhat astringent"—(*U. S. P.*).

III. *CINNAMOMUM ZEYLANICUM* (*U. S. P.*), *Ceylon cinnamon*.—"Long, closely rolled quills, composed of 8 or more layers of bark of the thickness of paper; pale yellowish-brown; outer surface smooth, marked with wavy lines of bast-bundles; inner surface striate; fracture short-splintery; odor fragrant; taste sweet and warmly aromatic"—(*U. S. P.*).

Chemical Composition.—The various species of cinnamon differ but little chemically, the chief constituent being their volatile oil (see *Oleum Cinnamomi*), which occurs to the amount of 1 per cent in cassia bark, but more sparingly ($\frac{1}{2}$ to 1 per cent) in that from the Ceylon variety. The latter, however, has by far the finer flavor. The principal constituent of cinnamon oil is *cinnamic aldehyde* ($C_6H_5CH:CHCHO$) together with cinnamyl-acetic ester and a little cinnamic acid. Holmes, in 1890, obtained from the oil distilled from the leaves *eugenol*, as chief constituent; a hydrocarbon resembling cymene in odor, little benzoic acid, and less cinnamic aldehyde. Cinnamon, according to the older analysis by Vauquelin, contains volatile oil, tannic acid (see investigation by T. R. Thornton, *Amer. Jour. Pharm.*, 1895), coloring matter, resin, an acid (cinnamic), and ligneous fiber; starch has been found in it. S. Martin, in 1868, obtained *cinnamomine*, a body identified as *mannite* by Wittstein, in 1869. Ceylon cinnamon leaves upon incineration about 4 or 5 per cent of ash.

Action, Medical Uses, and Dosage.—Stimulant, tonic, stomachic, carminative, and astringent; also reputed emmenagogue, and capable of diminishing the secretion of milk. The tincture of the bark is useful in *uterine hemorrhage* and *menorrhagia*, given in drachm doses in sweetened water, and repeated every 5, 10, or 20 minutes, or as may be required. A tincture of the oil (3j) in 98 per cent alcohol (3viii), is preferable, given in from 5 to 30-drop doses, repeated as often as necessary. For *post-partum* and other *uterine hemorrhages*, it is one of the most prompt and efficient remedies in the *Materia Medica*. To a limited extent it controls hemorrhage from other parts of the body, yet its most direct action is upon the uterine muscular fibres, causing contraction and arresting bleeding. Upon the nervous system cinnamon first stimulates and then depresses. Cinnamon is generally used to correct the effects, or improve the flavor of other drugs, and is one of the best additions to cinchona bark for correcting the nausea or vomiting sometimes occasioned by that drug. Internally, it is very useful in *diarrhæa*, *colic*, *cramp of the stomach*, *flatulency*, and to allay *nausea* and *vomiting*. Dose of the powder, from 5 to 20 grains; of the tincture, from 10 to 60 drops; tincture of oil, 5 to 60 drops. Specific cinnamomum, 10 to 60 drops (see *Oil of Cinnamon*).

Specific Indications and Uses.—Post-partum and other uterine hemorrhages with profuse flow, cold extremities, and pallid surface; hæmaturia; hæmoptysis.

Related Products.—*CASSIA BUDS* (*Flores cassiæ*) or *Clavelli cinnamomi*. The immature pedicellate fruits of one or several species of *Cinnamomum*. Though smaller, they resemble cloves somewhat, though their taste and odor is nearly like that of cinnamon. They contain tannin and an essential oil.

CASSIA TWIGS.—These are the small branches of the same tree yielding *cassia lignea*. They are about 2 feet long, vary in thickness, and possess a cinnamon flavor.

IAHPINGO.—The calyx of a lauraceous tree common to Peru and Ecuador. It consists of an enlarged, woody calyx from 1½ to 2 inches broad, funnel-shaped though shallow, the cup-like cavity being surrounded by an irregular, broad, usually recurved margin. It is of a deep-brown color, smooth internally, and veiny and rough on the exterior. Its taste is sweet and aromatic, resembling that of cinnamon, for which it is employed as a substitute in Ecuador. The bark of the twigs resembles cinnamon, being furnished in small quills (*Pharmacographia*).

CLOVE BARK OF CASSIA CARYOPHYLLATA (*Cortex caryophyllatus*).—This Brazilian bark has a cinnamon-like, mucilaginous taste and the odor of cloves. It is the product of *Dicypellium caryophyllatum*, Nees. The bark is thin (¼ inch), smooth, or slightly rugose, is of a rich brown color, occasionally bluish-brown, and when broken displays a nearly white line close to the external margin. It breaks with a short fracture. It is occasionally found in market, but is most largely employed in Brazil as a substitute for cinnamon, whose properties it resembles.

CULILAWAN BARK.—This bark, employed by the natives of Molucca and occasionally sold on the market, is the product of *Cinnamomum Culilawan*, Nees. It comes in somewhat thick (½ to ¾ inch) curved or flat pieces. It breaks with a short, fibrous, somewhat corky fracture, and has internally a brownish color, while on the external surface it is gray or brown. It has a mucilaginous, aromatic taste, and a mixed odor of cinnamon, sassafras, and cloves.

MASSOY BARK.—Several aromatic barks bear this title. A New Guinea bark yielded a oil to Schimmel & Co., resembling that of cloves and nutmeg. The true massoy barks, however, are those believed to be derived chiefly from the *Cinnamomum Burmanni* var. *Kiamis*, *Cinnamomum zanthoxylon*, and *Sassafras gosianum* (see *P. J. Trans.*, 1888).

CIRSIIUM.—CANADA THISTLE.

The root of *Cirsium arvense*, Scopoli.

Nat. Ord.—Compositæ.

COMMON NAMES: *Canada thistle*, *Cursed thistle*.

Botanical Source.—This plant, called in England *Cursed thistle*, has a perennial, creeping, very long root, extremely tenacious of life, with a stem 3 or 4 feet in height, having a branching panicle at the top. The leaves are alternate, oblong or lanceolate, sessile, smooth, or slightly woolly beneath, sinuate-pinnatifid, and prickly margined. The heads are rather small, numerous, and imperfectly dioecious. The flowers are rose-purple. The involucre round or ovate, with minute spines; and the scales close pressed, and ovate-lanceolate (W.—G.).

History.—Canada thistle grows in various sections of the United States, in cultivated fields and pastures, roadsides, and waste places, flowering from June to August. It is an extremely troublesome plant to the farmer, requiring his utmost vigilance to extirpate it from his fields. The involucre is the only part of the plant that can be handled with safety. The root is the part employed, which

yields its properties to water. Herman J. Pierce has made a chemical analysis and found a volatile alkaloidal principle difficult to obtain crystalline, of narcotic odor, soluble in ether, chloroform and alcohol; an organic acid, resin, etc., while starch, tannins and glucosids were absent (*Amer. Jour. Pharm.*, 1896, p. 529).

Action, Medical Uses, and Dosage.—Tonic and astringent. Used principally, boiled with milk, in *diarrhœa* and *dysentery*; some recommend the addition of dried codfish skin to the decoction. Also, used as a local application to some *cutaneous diseases*, *ulcers*, and in *leucorrhœa*.

CLEMATIS.—VIRGIN'S BOWER.

The fresh stems, leaves, and blossoms of *Clematis virginiana*, Linné.
Nat. Ord.—Ranunculaceæ.

COMMON NAMES: *Virgin's bower*, *Ladies' bower*, *Love vine*, *Traveler's ivy*.

ILLUSTRATION: Lloyd's *Drugs and Med. of N. A.*, Vol. I, Pl. 1.

Botanical Source.—*Clematis virginiana* is a perennial, climbing plant, with a stem from 8 to 15 feet or more in length, supporting itself on shrubs, fences and brushwood, by means of its long petioles. The leaves are opposite, deep-green, and ternate; the leaflets ovate, cordate, acuminate, lobed, cut-dentate, and from 2 to 3 inches in length by 1 or 2 in breadth. The flowers are in paniculate clusters, and dioecious; the panicles being large, axillary, and dichotomous. Sepals 4, white, spreading, oval-oblong, obtuse-petaloid. Stamens from 28 to 36. The fruit is furnished with long, plumose tails, appearing in large, downy tufts. The seeds are compressed (W.).

History.—The *Clematis virginiana* is a native of the United States, and grows by river banks, in hedges and thickets, from Canada to Georgia and the Mississippi. It flowers in July and August; the parts used are the bark, leaves, and blossoms, which yield their virtues to water or alcohol. The leaves should be gathered when they are fully grown, say in August. The fresh drug only should be employed, as most of its properties are dissipated in drying. *Clematis* is not found as a drug in commerce. Alcohol takes up the properties of *clematis*, yielding a green tincture, which, upon exposure to light, turns brown. This and all of the below-mentioned species of *Clematis* have been used in medicine to some extent, but only this species and *Clematis recta* are now employed, and chiefly in domestic practice and by Homœopathic physicians. Though never favorite remedies, they have probably fallen into undeserved neglect on account of having been used in the dried instead of the fresh state. They should be given a proper trial, and their worth or worthlessness established.

Description.—The leaves and flowers are described above. "The stem attains a diameter at the base from $\frac{1}{2}$ inch to 1 inch, and has a spongy, ligneous texture. When recent, it is covered with a thin brown bark. The wood is coarsely divided into distinct medullary rays, between which, when the plant is recent, are deposited layers of a greenish substance, which contains the acrid principles." (J. U. Lloyd, in *Drugs and Med. of N. A.*, Vol. I, p. 7).

Chemical Composition.—According to Rafinesque (1830) a peculiar body resembling gluten, and known as *clematin*, exists in the flowers of *C. virginiana* and *C. Viorna*. The fresh plant (*Clematis virginiana*), according to Prof. J. U. Lloyd, who examined it chemically, has a peculiar, unpleasant odor, and a taste at first rank and disagreeable, but, after prolonged chewing, becomes acrid and irritating, not followed by pain, but rather leaving "a dry, metallic-like roughness of the tongue and mouth." When distilled with water a neutral distillate, having an

Fig. 75.

Clematis virginiana

odor recalling that of skunk-cabbage, was obtained. This odor may be removed by agitation with chloroform or benzol. If this solution be spontaneously evaporated, "a colorless, oily substance remains, which is the characteristic principle of the plant, but which evaporates by exposure." He found the distillate, when inhaled, to be a pulmonary irritant, giving a sensation similar to that produced by sulphurous acid gas. No alkaloid, either volatile or fixed, was found. Besides the usual plant constituents the plant contains grape-sugar. (See paper by Prof. J. U. Lloyd, in *Drugs and Med. of N. A.*, Vol. I, p. 10).

Action, Medical Uses, and Dosage.—The various species of clematis, when applied to the skin in a fresh state, blister it; and if taken internally, act as corrosive poisons. Both drying and boiling destroy the virulent property. They have been used externally in the treatment of several *cutaneous affections*, and in form of a liniment, made with oil, for the cure of *itch*; internally, as diuretics and sudorifics in *chronic rheumatism*, *palsy*, etc., in minute doses. The extract, in doses of 1 or 2 grains, is recommended for *osteocopic pains*. The green leaves bruised are sometimes employed to produce vesication, also, as an escharotic and detergent for *venereal* and other foul and *indolent ulcers*.

Clematis virginiana has been highly spoken of as a nervine in *uterine diseases*. Place 2 drachms of the dried leaf into a cup filled with hot water, cover it, and allow it to stand until the liquid is cool enough to drink; strain, sweeten with sugar if desired, and let the patient drink it at once. Repeat as often as may be required, the doses being regulated by its effects upon the system.

Like *Clematis recta* (which see), this species produces painful eczema-like eruptions, which may result in small painful ulcerations. Prof. E. M. Hale, M. D., has found it fully equal to *Clematis recta*, being particularly useful in *nervous crachism*, *insomnia*, *neuralgic and rheumatic headache*, *toothache*, *reflex neuroses of women* from ovarian or urinary irritation, *neuroses of men* with pain in testicles and bladder, *cystitis*, *urethritis*, *gonorrhœa*, *orchitis*, and *swellings of the inguinal glands*. Following the law of *similia*, he also found it useful in "*eczema*, *herpes zoster*, and *pustular eruptions* on the scalp and face of children." A good tincture may be prepared as follows: *Clematis* (fresh stem, leaves, and flowers), 1 part; alcohol, 2 parts; bruise to an even pulp, add the alcohol, mix thoroughly, and allow to macerate in a close vessel for 10 days. Express and filter (*D. and M. of N. A.*). As clematis acts very much after the manner of *pulsatilla* and its congeners, it should be tried in fractional doses in the complaints for which such drugs have an established reputation. (For uses of other species see *Related Species*). Dose, $\frac{1}{15}$ to 5 drops, well diluted.

Related Species.—Prof. Landerer, of Greece (1877), reported a case of *epilepsy* cured after futile attempts with other medicine, by a species of *Clematis*, either *C. cirrhosa* or *C. sylvestris*. Also rubefacient and vesicant.

Clematis recta (*erecta*), Linné. *Upright Virgin's bower*.—The *Flammula Joris* of old medical writers and the first species introduced as a medicine (*D. and M. of N. A.*). This species, like others of its family, will produce a painful pustular, eczema-like eruption, which may result in blebs or bullæ, and even develop into small painful ulcers. It has been used to some extent in Homœopathy, and is mentioned by Prof. Webster (*Dynam. Therap.*) in the conditions named below. It appears to affect both the male and female reproductive organs, influencing both the testes and ovaries. *Orurian indurations* and *chronic gonorrhœal orchitis* are said to be relieved by it. It is also reputed useful in other after-effects of *gonorrhœa*, as *gleet* and *incipient stricture*. It relieves *irritation of the urinary tract*, especially the *venical irritation* of nervous women with ovarian derangements. *Dysuria* and *urinal retention* are also occasionally benefited by it. Homœopaths employ it in *chronic scrofulous* and *syphilitic skin diseases*, especially when mercurialization has been carried too far. Foul, vesicular, and pustular eruptions, *ulcers*, *syphilitic excrescences*, *eczema*, and *irritated and swollen eyelids*, involving the meibomian glands, are conditions in which they claim success from its use. A Homœopathic tincture may be used in the proportion of 10 to 15 drops to 4 fluid ounces of water, the dose of which is a teaspoonful several times a day. Störck (1769) employed *Clematis recta* in *old ulcers*, *secondary syphilis*, *headache*, and *carcinoma*. He also pointed out its diuretic action, a view confirmed by Prof. Sauveur, in 1866, who claims to have cured *Bright's disease* with its infusion.

Clematis vitalba, Linné.—The common species of Europe and only one in England. "*Virgin's bower*, *Traveler's joy*, *Love vine*, *White vine*, *Ladies' bower*, *Old Man's beard*, *Smoke wood*, *Wild vine*, *Bind-with*, *Hedge vine*, and *Climbers*" (*D. and M. of N. A.*). *Wild clematis*. Gaube extracted a principle from this plant to which he gave the name *clematine*. It is alkaline, and forms a neutral compound with sulphuric acid, which crystallizes in hexagonal needles. Besides this principle, he also detected an essential oil, to which it owes its properties, tannin, mucilaginous substances, and a small amount of earthy salts.

The seeds of clematis, given in infusion, have been found serviceable in *albuminuria*, even when general *anasarca*, *amblyopia*, *incipient hypertrophy of the left ventricle*, without valvular lesion, and which condition is, as M. Traube has shown, always a result of abnormal conditions of the kidneys, and other symptoms peculiar to this disease were present. The effects of the remedy were quite prompt, a profuse diuresis, followed by a gradual diminution of albumin in the urine, and a rapid disappearance of the *anasarca*, and other symptoms. This infusion has likewise proved efficient in other serous affections due to other maladies of the abdominal viscera (Prof. Sauveur, 1888). The roots of the *C. vitalba*, boiled for a short time to diminish their acrimony, and then infused in boiling oil, were applied to the skin several times a day, in *itch*, and a cure was effected in 12 or 15 applications. The plant, boiled in oil and mixed with wax and verdigris, was formerly esteemed a remedy for *tinea*.

Clematis Florna, Linné, or *Leather flower*, which is more common in the western states, and may be found growing in woods from Pennsylvania southward, may, probably, be employed as a substitute for the above. It differs from it in having a cylindrical, striate stem; with opposite, decompound, pinnately divided leaves, consisting of from 9 to 12 ovate-lanceolate leaflets, acute at each end, entire or 3-lobed; flowers large, purple, nodding, solitary, axillary, campanulate; sepals thick, leathery, acuminate, and peduncles from 3 to 6 inches long, with a pair of small, simple, entire leaves near the middle (W.).

Clematis Pitcheri, Torrey and Gray.—From Illinois westward. This and above species are probably varieties of the same species. It has single, dull-purple flowers, having thick, leathery, valvate sepals. It is also known as *Leather flower*.

Clematis crispa, Linné.—Southern United States. This is thought to be the most acrid of the indigenous species. It is known in the south as *Blue jasmine* and *Curled Virgin's bower*. It has single nodding flowers, with "purplish-blue sepals, with dilated thin margins" (*D. and M. of N. A.*).

Clematis Flammula, Sweet-scented Virgin's bower.—France and other parts of south Europe. Has fragrant white flowers and is cultivated for ornamentation (*D. and M. of N. A.*).

Clematis Viticella, Linné; *Blue clematis*.—South Europe, particularly France. Cultivated, and has blue flowers (*D. and M. of N. A.*). Formerly esteemed in *itch* and *leprosy*.

Clematis verticillaris, De Candolle; *Whorl-leaved Virgin's bower*.—Rare northern species. "It has large, 4-sepaled, purple flowers, with thin, spreading sepals" (*D. and M. of N. A.*). Cultivated for ornament.

Clematis alpina, Miller.—Southern Europe, in mountainous regions. Analogous to preceding (*D. and M. of N. A.*).

Clematis ligusticifolia, Nuttall; *Wild sarsaparilla*.—Western United States. Closely resembles *Clematis virginiana*. Root used by New Mexico Indians as an alterative (*D. and M. of N. A.*).

Clematis dioica, Linné.—Jamaica. Used as a rubefacient (*D. and M. of N. A.*). The root, oiled with sea water, acts as a powerful hydragogue cathartic, and is useful in *dropsy*; and an infusion of the leaves and flowers removes spots and freckles from the skin.

Clematis mauritiana, Linné.—Madagascar. "Probably the most acrid of all the genus" (*D. and M. of N. A.*). Employed by the negroes of the Isle of France to blister the cheek for the relief of toothache.

ONICUS BENEDICTUS.—BLESSED THISTLE.

The leaves and flowering heads of *Oniclus benedictus*, Gaertner (*Centaurea benedicta*, Linné; *Carduus benedictus*).

Nat. Ord.—Compositæ.

COMMON NAMES: *Blessed thistle*, *Holy thistle*.

Botanical Source.—Blessed thistle is an annual, branched, woolly plant, with a fibrous, whitish root, sending out several roundish, reddish stems, 1 or 2 feet high. The leaves are amplexicaul, somewhat decurrent, nearly entire, pinnated or deeply pinnatifid, more or less hairy; the upper leaves sessile; the lower ones petioled. The flowers are yellow, and borne in terminal bracteate heads. involucre ovate; scales close-pressed, coriaceous, extended into a long, hard, spiny, innated appendage; lateral spines conical and distant. The florets of the ray are sterile, slender, and as long as those of the disk. Fruit longitudinally and regularly striated, smooth, with a broad, lateral scar. Pappus triple, as it were; the outer being the horny, short, crenated margin of the fruit; the intermediate consisting of 10 long, stiff setæ; the inner, of 10 short setæ; all the setæ alternating with each other (L.).

History.—This plant is common to southern Europe and the Levant, and has been introduced into this and several other countries. It flowers in June, at which time the leaves and tops should be collected, as the plant is at its highest degree of medicinal power; they should be thoroughly and speedily dried, and kept free from moisture, light, and free access of air. Their odor is faint and rather disagreeable, and their taste is exceedingly bitter. Their properties are added to water or alcohol, forming a pleasantly-bitter draught when infused with the former fluid, but a sickening and repulsive decoction.

Chemical Composition.—The leaves yield, upon analysis, an amorphous, brownish-yellow, bitter principle, resin, a fixed oil, gum, sugar, albumen, some salts, etc. The bitter principle was discovered, in 1839, by Nativelle and by him named *cnicin* ($C_{12}H_{18}O_{12}$, Scribe), and is supposed to be the active constituent of the plant. It crystallizes in transparent white needles, which have a bitter taste, are odorless, neutral, unaffected by the atmosphere, are fused and decomposed by heat, slightly soluble in cold, but more so in boiling water, sparingly soluble in ether, but readily in alcohol. Chemically it approaches salicin. Vomiting is produced by it in doses of 5 or 6 grains; 7 or 8-grain doses have proved beneficial in periodical fevers (see *Chem. Gaz.*, Vol. II, p. 462).

Action, Medical Uses, and Dosage.—A cold infusion is tonic; a warm infusion diaphoretic and emmenagogue; and, if strong, emetic. Used as a tonic in *loss of appetite, dyspepsia, and intermittent diseases*. Valuable also in the forming stage of *febrile and inflammatory affections*. Colds may be broken up with it, and it acts well in *menstrual suppression* from cold. Dose of the powder, from 10 to 60 grains; of the infusion, 2 fluid ounces; specific *cnicus benedictus*, 5 to 10 drops, every 4 hours.

Related Species.—*Centaurea calcitrapa*, Linné; *Star thistle*.—Europe. Naturalized to some extent in the United States. Flowers purple, and herb has a bitter taste. Virtues like those of blessed thistle.

Centaurea cyanus, Linné; *Blue bottle*; *Corn flower*.—Europe. Naturalized and cultivated in flower gardens in the United States. Florets blue. Besides being an ingredient of some fumigating powders, these flowers have virtues similar to the preceding plants.

COCA (U. S. P.)—COCA.

"The leaves of *Erythroxylon Coca*, Lamarck"—(U. S. P.). This is the *ERYTHROXYLON* of the U. S. P. of 1880.

Nat. Ord.—Lineæ.

Botanical Source.—This is a shrub growing about 4 feet high, with the leaves ovate, alternate, thin, membranous, flat, opaque, acute at both ends, the apex almost mucronate, quite entire, tri-nerved in the middle with fine connecting veins on either side of the midrib, a slightly curved line extending from one end of the leaf to the other (the crossing of larger veins rendering the leaves somewhat areolated), dark-green above, paler beneath, $1\frac{1}{2}$ to 2 inches long, an inch or more in their greatest width, and on short, delicate foot-stalks. The petioles are from 2 to 4 lines long, with a pair of intrapetiolarly ovate-lanceolate, brown, acute stipules, upon the back of the outside of which the petiole is articulated, and from which the leaf readily falls away, leaving the branches scaly with the persistent stipules. The flowers are small, white, numerous, and borne in fascicles from the branches where the leaves have fallen away, bracteated. The peduncles are about as long as the flower, and sharply angled. Calyx 5-cleft, 5-angled at the base; segments acute. Petals 5, alternate with the calyx segments, oblong, concave, wavy, with a lacerated and much plaited membrane arising from within and above the base. Stamens 10, monadelphous; filaments longer than the pistil, combined below into a rather short cylindrical tube. Ovary oval, 3-celled, 3-seeded; styles 3, about as long as the ovary, distinct from the very base, not consolidated; stigmas thickened. The fruit (by abortion), is an oblong or ovoid drupe, 1-seeded, red, and obscurely furrowed when dry; the nut is oblong and furrowed (L.).

History.—Coca grows in moist and woody regions on the eastern slopes of the Andes, from 2000 to 10,000 feet above the level of the sea, and is highly valued and cultivated by the natives of Peru, Chili, and Bolivia, who make great use of it as a medicine, and as an article of diet. It answers as a substitute for the tea, coffee, tobacco, hashish, opium, etc., of other nations. In some sections the plant produces three crops annually. The natives masticate the dried leaves with finely powdered chalk or lime, or with a highly alkaline substance prepared from roasted potatoes and the ashes of various plants, which they call *llipta*. Its use is not confined to the rich; the poor laboring classes make great use of it as a stimulant and imaginary nutrient, as it enables them to endure fatigue and exertion for many hours, and even for several days, with but little nourishment.

of any other kind; and while under its influence they are said to perform prodigies of labor. The leaves after being gathered must be dried as quickly as possible, and be kept perfectly free from moisture and dampness; they then have a rather pleasant odor, recalling that of tea, and a bitter, aromatic, and slightly astringent taste.

Coca shrub has been cultivated successfully in Ceylon, India, and Java. In the latter country the cultivated species differ sufficiently from the *Erythroxylon Coca* to have been designated as the variety *E. Coca*, var. *Spruceanum*, Burck.

Description.—Two South American cocas are found in commerce. One known as *Huanuco* or *Cuzco Coca*, is derived from places of those names in Peru, the cities being located south of the central part of the state; and *Truxillo* or *Trujillo Coca*, coming from the northern portion of Peru. The latter kind has pale-green leaves, which are thin and easily broken, not so large but more pointed than those of Huanuco coca, which are coriaceous, thicker, and have a much deeper green color. The Truxillo leaf is said to be identical with that furnished by the Java shrub. Bolivian coca is regarded as finer than that grown in Peru. It is identical in appearance with the Huanuco variety. Coca is marketed in *cestos* or bags of from 25 to 50 pounds each. The *U. S. P.* thus describes coca: "Varying between ovate, lanceolate, and obovate-oblong, and from 2 to 5 or 7 Cm. ($\frac{3}{4}$ to 2 or $2\frac{3}{4}$ inches) in length; short-petiolate, entire, rather obtuse or emarginate at the apex, slightly reticulate on both sides, with a prominent midrib, and on each side of it a curved line running from base to apex; odor slight and tea-like; taste somewhat aromatic and bitter. When chewed it temporarily benumbs the lips and tongue"—(*U. S. P.*).

Chemical Composition.—Wackenroder, in 1853, failed to isolate any of the active principles of coca leaves, but obtained its peculiar tannic principle to which

later the name *coca-tannic acid* was given. Several alkaloids have since been observed in coca. *Cocaine* ($C_{17}H_{21}NO_4$), was first noticed by Gædeke, in 1855, who named it *erythroxiline*, but it was better defined by Niemann, in 1860, who gave it its present name. When heated with concentrated hydrochloric acid, it is resolved into benzoic acid, methyl alcohol, and a new base called *ecgonine* ($C_8H_{13}NO_3$, or $CH_3.NC_6H_4.CHOH.CH_2.COOH$); hence *cocaine* is *methyl-benzoyl-ecgonine* (W. Lossen, 1862). Ecgonine crystallizes from alcohol in monoclinic prisms, easily soluble in water, less so in alcohol, and insoluble in ether. It has a sweetish bitter taste. COCAINE occurs in large 4 to 6-sided monoclinic prisms, and when pure, is without odor and color. Cocaine is readily soluble in chloroform, ether, carbon disulphide, benzene, petroleum ether, petrolatum (melted), and in volatile and fixed oils. It is much less soluble in alcohol than in the above solvents,

while water dissolves it with difficulty (1 part in 704 at $12^\circ C.$ [$53.6^\circ F.$]) (Niemann); more than 1300 parts of cold water (Paul), being required. Cocaine is bitterish, and produces upon the tongue an evanescent numbness. It can not be kept in aqueous solution on account of its tendency to split into methyl-alcohol, ecgonine, and benzoic acid. Cocaine is strongly alkaline in reaction,

Fig. 76.

Cocaine alkaloid, commercial product crystallized from alcohol. X. 50 diameters.

Fig. 77.

Cocaine hydrobromate. Crystals formed by spontaneous evaporation of aqueous solution X. 50 diameters.

producing with acids crystallizable salts, which, as a rule, are bitter, and dissolve freely in water and alcohol. Ether does not dissolve them. They all possess the property of benumbing the tongue in a greater degree than does the alkaloid cocaine. For the details of Squibb's process of preparing cocaine by percolating coca leaves with a 5 per cent solution of sulphuric acid, and abstracting the alkaloid with kerosene oil after rendering alkaline with sodium carbonate, see *Ephemeris*, 1887, p. 906.

Cocaine may also be considered a methyl derivative of *benzoyl-ecgonine* ($C_{17}H_{19}NO_3$, COC_2H_5), which is another alkaloid occurring in coca leaves. *Isatropyl-cocaine* ($C_{17}H_{21}NO_3$), a very poisonous, amorphous alkaloid, has also been found in this drug (Liebermann, 1888). With hydrochloric acid it splits into methyl-alcohol, ecgonine, and *isatropic acid* (C_8H_7COOH), thus disclosing an analogy to cocaine, the relationship being similar to that exhibited in the class of alkaloidal bodies known as *tropeines* (see *Atropine*). *Cinnamyl-cocaine* ($C_{18}H_{21}NO_3$), another alkaloid existing in coca leaves, is likewise analogous to cocaine, yielding by decomposition *cinnamic acid* (Geisel), or *isocinnamic acid* (Liebermann, 1890), instead of benzoic acid. *Cocamine* ($C_{18}H_{23}NO_4$, Hesse, 1889), being present in *Erythroxylon nova granatense*, or Truxillo bark, in the amount of 0.6 per cent, yields *cocaic acid* ($C_8H_7O_3$), which Hesse pronounces, however, identical with *isatropic acid*. Liebermann and Geisel (1891), found in coca leaves from Java *benzoyl-pseudo-tropeine* ($C_{18}H_{21}NO_3$), which, when heated with hydrochloric acid, splits off *pseudo-tropeine* (C_8H_7NO). The alkaloid *hygrine*, named by Lossen, was previously observed by MacLagan. According to Hesse (1887), it is a yellowish, strongly basic oil easily soluble in ether, chloroform, and alcohol, less so in water, forming salts with acids. Its diluted solutions in acids are fluorescent. Its formula is probably $C_{10}H_{15}N$, which points to its being a homologue of quinoline (C_9H_7N). *Cocaicine* (Bender, 1885), is one of several undetermined coca alkaloids. Among other constituents of coca leaves may be mentioned, chlorophyll, resin, traces of essential oil, the coca-tannic acid before mentioned producing a green-black color with ferric salts; a wax crystallizing from alcohol in white granules, and melting at $70^\circ C.$ ($158^\circ F.$) (Niemann), and inorganic salts. The amount of total alkaloids in coca leaves has been found to vary from 0.2 to 0.8 per cent, seldom reaching 1 per cent. For comparisons of assay methods, see *Amer. Jour. Pharm.*, 1895, pp. 489 and 572.

Action, Medical Uses, and Dosage.—In large doses, coca is said to cause delirium, hallucination, and finally cerebral congestion. In medium doses it acts as a stimulant, increasing the temperature of the body, as well as the respiration and frequency of the pulse; in a moderate dose it excites the nervous system in such a manner as to render the performance of muscular exertion much easier, and producing a sensation of calmness. According to Dr. Mantegazza, its use has produced an erythematous eruption resembling pityriasis, with a sense of prickling and itching; the intoxication produced by it, differs from that resulting from the use of alcoholic drinks, the symptoms being feverishness, increased heat of the surface, palpitation, photopsy, headache, vertigo, increased frequency of the pulse, a peculiar roaring tinnitus, strong desire for active locomotion, with increased sense of strength and agility, exaltation of the intellectual sphere, sense of isolation, followed by a feeling of intense calm and comfort, complete apathy, sleep, odd and rapidly changing dreams, and from which the patient awakes without debility or indisposition of any kind. The leaves of coca, chewed or taken in a weak infusion, stimulate the gastric nerves and greatly facilitate digestion; and are also useful in relieving the sense of fatigue from excessive mental or physical exercise. A drachm of the leaves chewed produces a feeling of comfort in the stomach, and upon repeating the dose a few times, a slight burning sensation is experienced in the mouth and pharynx, with increased thirst, rapid digestion, and a substitution of the coca odor in the stools for that ordinarily present.

More recently, M. Moreno, who made some interesting experiments upon the effects of coca and cocaine, remarks, that coca gives much less arterial tension than coffee, as he has convinced himself with the aid of the sphygmograph. Relatively to its action, M. Weddell has observed: "One of two things, either coca incloses some nutritive principles which directly sustain the forces, or else it simply deceives the hunger, by acting upon the economy as an excitant."

M. Moreno has submitted animals to an insufficient alimentation or to absolute inanition, and in these conditions he has observed that those to whom he administered coca lost more of their weight and died more speedily. He concludes that if coca sustains the forces, that is to say, permits man to forget hunger, it is not, however, as an aliment, and does not succeed in satisfying it. He has carefully studied the special action exerted by this substance upon the nervous system. According to him it determines (1) phenomena which place it with strychnine (tetanic and spontaneous convulsions, and, upon the least excitation of the animals, death); (2) in a small dose, it provokes a remarkable excitation of sensibility, dilatation of the pupil, irregularity of the movements; the animals seem to have lost the coördinating power of their movements. Lastly, in large doses, it causes a diminution, followed by exhaustion, of sensation, without motility being completely abolished, and in all the cases, the pupils remain dilated. Like tea and coffee, coca lessens the elimination of urea, acting thereby indirectly as a food, though not a food in itself. That hunger is staved off by it is probably due to a benumbing effect upon the nervous supply of the stomach.

That the habit of using coca will grow upon one, is illustrated by its effects upon the mountaineers of the Peruvian Andes (see *History*), who employ it to lessen fatigue, and to guard against the pulmonary hemorrhage likely to occur at high altitudes. The habitual coca-chewer acquires a general apathetic state and his step becomes uncertain. Deep purplish circles surround his sunken eyes, his lips tremble, a peculiar blackish colorization is observed at the angles of the mouth, the teeth become green and encrusted, and an intolerably offensive odor is imparted to the breath. Extreme emaciation, with intractable sleeplessness, and anasarca ensue and finally death completes the destruction.

Coca is a remedy for defective innervation, as evidenced by imperfect digestion, even though the appetite remains normal, and when the disorder is associated with occipital and post-cervical pain, vertigo and inability to stand for any length of time (Scudder). It increases the flow of gastric juice, improves the tone of the stomach, and relieves gastric pain. In fact, atonic states of the nervous system and the stomach, are the conditions in which it appears to exert the best effects. *Hysteria* is often cured by it, while, in *chorea*, it may relieve by toning the muscles and increasing nerve power, in this manner giving the patient better control over the muscular movements. From 10 to 15 drops of specific erythroxyton will overcome *insomnia*, caused by a gloomy state of the mind, and sometimes *asthma* is slowly, but permanently, cured by the drug (Locke). In the treatment of the *opium habit* it generally fails.

Coca has been successfully used in *irritative or atonic dyspepsia*, *flatulency*, *colic*, *gastralgia*, *enteralgia*, *hypochondria*, *spinal irritation*, *idiopathic convulsions*, *nervous rethism*, and in the *debility* following severe acute affections, *anemia*, *scurvy*, etc. In large doses it has been proposed in *tetanus* and *hydrophobia*, though no trustworthy reports of its efficacy are as yet forthcoming. Prof. Scudder (*Spec. Med.*) suggests that it may be useful in "the early stages of *tuberculosis*, by enabling the person to take the exercise so much needed to burn the imperfect materials in the blood." There is no doubt but that it exerts some control in *wasting diseases* in general. It is reputed useful in *relaxed states of the vocal chords*, and in the granular form of *pharyngitis*; and to allay the thirst accompanying *diabetes*, and the inordinate hunger of the *insane* and *epileptics*. Like tea, coffee, guarana, etc., it is an effectual remedy in *migraine*, or *nervous headache*, and is not without utility in *functional impotence* and *spermatorrhœa*, when due merely to a condition of general debility. Coca has been suggested as an agent to control hunger, thirst, and fatigue for armies during long and forced marches, but, owing to its scarcity, it will probably never be used for this purpose.

Three or 4 drachms of the leaves is a medium dose, whether chewed or used in infusion; of the hydro-alcoholic extract, 10 to 15 grains, in pill form; the dose of specific erythroxyton is from 5 to 30 drops.

Specific Indications and Uses.—Defective innervation with dizziness, impaired digestion, occipital and post-cervical pain, and inability to stand for a length of time; migraine; fatigue; weariness and mental and physical exhaustion; labored and difficult breathing, with normal temperature; inordinate hunger and thirst.

COCAINÆ HYDROCHLORAS (U. S. P.)—COCAINE HYDROCHLORATE.

FORMULA: $C_{17}H_{21}NO_4 \cdot HCl$. **MOLECULAR WEIGHT:** 338.71.

"The hydrochlorate of an alkaloid obtained from Coca"—(U. S. P.).

SYNONYMS: *Cocaine hydrochlorate, Cocaine muriate.*

Preparation.—According to the *British Pharmacopœia*, cocaine hydrochlorate may be obtained by dissolving an acidulated alcoholic extract of coca in water, rendering it alkaline by means of sodium carbonate, and agitating it with ether. Evaporate the ethereal solution, purify by means of acidulated water, shake out with sodium carbonate and ether, repeating the above process, decolorize, and, finally, neutralize with hydrochloric acid, and then recrystallize. Cocaine is usually not made by pharmacists.

Description.—The U. S. P. describes this salt as "colorless, transparent crystals, or a white, crystalline powder, without odor, of a saline, slightly bitter taste,

Fig. 78.

Cocaine hydrochlorate. Crystals formed by spontaneous evaporation of a drop of saturated aqueous solution. X. 100 diameters.

and producing upon the tongue a tingling sensation followed by numbness of some minutes' duration. Permanent in the air. Soluble at 15° C. (59° F.), in 0.48 part of water, and in 3.5 parts of alcohol; very soluble in boiling water, and in boiling alcohol; also soluble in 2800 parts of ether, or in 17 parts of chloroform. On heating a small quantity of the powdered salt for 20 minutes at a temperature of 100° C. (212° F.), should not suffer any material loss (absence of water of crystallization). The prolonged application of heat to the salt, or to its solution, induces decomposition. At 193° C. (379.4° F.) the salt melts with partial sublimation, forming a light, brownish-yellow liquid. When ignited, it is consumed without leaving a residue"—(U. S. P.).

Tests.—"The salt is neutral to litmus paper. On adding 5 drops of a 5 per cent solution of chromic acid to 5 Cc. of a 2 per cent solution of cocaine hydrochlorate, a yellow precipitate is produced, which redissolves on shaking; on now adding 1 Cc. of hydrochloric acid, a permanent, orange-yellow precipitate will be formed. If a small quantity of the salt be rubbed, with a glass rod, on a dry, white porcelain surface, with an equal bulk of mercurous chloride, and the mixture then breathed upon, it will acquire a dark-gray or grayish-black color. The aqueous solution of the salt yields, with silver nitrate T.S., a white precipitate, insoluble in nitric acid. The addition of sulphuric or nitric acid to the salt, at the ordinary temperature, should develop no color. If 1 drop of a mixture of 1 volume of decinormal potassium permanganate V.S., and 2 volumes of water be added to 5 Cc. of a 2 per cent solution of cocaine hydrochlorate mixed with 3 drops of diluted sulphuric acid, and contained in a small, clean, glass-stoppered vial, the pink tint produced by the permanganate should not entirely disappear within half an hour (absence of cinnamyl-cocaine and some other bases derived from cocoa)"—(U. S. P.). MacLagan's test is carried out as follows: Dissolve 1 grain (0.064 Gm.) of cocaine in 2 fluid ounces (56.5 Cc.) of water, add 2 drops of aqua ammoniæ (10 per cent), and stir well with a glass rod. When pure, a crystalline precipitate will be produced after a few minutes' stirring. The reliability of this test is doubted by Günther, but is upheld by Paul and Cownley (see *Pharm. Jour. Trans.*, Vol. VII, 1898, and Vol. VIII, 1899).

Action and Toxicology.—Most of the physiological action of cocaine has been determined from experiments upon frogs and the lower warm-blooded animals. Its action upon man has been gleaned principally from its therapeutic employment, and from its action in cases of poisoning by it. There appears to be

a difference in the effects produced by the parent drug and its alkaloid, as well as a difference produced by the fresh leaves of coca in its native habitat and the dried product as used in this country. When applied to mucous surfaces, as of the mouth, it first excites the parts, an action which is quickly followed by a sense of numbness, followed shortly by complete local anæsthesia. The same effects are felt upon all mucous surfaces, and are more quickly produced by hypodermatic injection. A sense of coldness after drinking cold water or drawing in the breath, is experienced in the mouth after the benumbing has taken place, similar to that following the application of peppermint or menthol, thus showing that while insensibility to pain may be effected, that the impression to cold is not wholly abolished. To produce a general anæsthesia of the parts quite large doses are requisite. Taken internally in small doses it increases peristaltic movements, while such movements are paralyzed by large amounts. Upon the pharynx, larynx, or nasal fossæ it effects a reduction of sensibility, so that examinations and small operations may be freely permitted. Applied to the conjunctival membranes local anæsthesia is produced though a sense of coldness when an unwarmed instrument is brought in contact with the parts is distinctly felt. The accommodation is impaired, and a partial pupillary dilatation is effected, which may however, be further increased by atropine. The vessels are constricted by it. Internally or hypodermatically administered, or even where absorption has taken place from its application to mucous surfaces, its effects upon the nervous system are very pronounced, and a number of fatal cases have been reported. It has been compared to Indian hemp in its effects upon the brain. Among the symptoms are mental confusion, disordered senses, a glowing sensation throughout the system, and in the beginning a sense of cheerfulness and contentment in some cases, of restlessness, nervous excitation, fear, and terror in others. Vertigo, tinnitus, dilated pupils with impairment of accommodation, headache, and a sense of passing from earth into air, is sometimes experienced. Sleep occasionally follows. The conjunctivæ and skin are pale, the heart's movement accelerated, and respiration quickened. In some cases nausea, vomiting, and eructations occur. When only that stage is reached in which a cheerful inebriation occurs, the insensibility to hunger and power to endure fatigue are striking, and muscular power is undoubtedly increased. Consciousness is usually lost, though this unconscious state may be only apparent, but rather an anæsthetic state. The more pronounced toxic effects vary somewhat. Besides nausea and vomiting, if consciousness still persists, a sensation of great thirst and dryness of the fauces and mouth are complained of. A very rapid, small, thready, and imperceptible pulse characterizes most cases, while in others a slow, feeble pulse and cyanotic state precede slow or arrested breathing. Pain is seldom felt. The breathing is generally slow, shallow, and labored, though at first it is generally quickened. Muscular trembling or even spasms may occur, and if the dose be large they are often severe and with epileptiform movements. Headache, vertigo, and carotid throbbing may be present, and in many cases hallucinations are experienced. Perspiration is sometimes profuse, and in some instances greatly increased diuresis has taken place. Outside of what is oxidized in the body, cocaine is eliminated by the renal organs. Even as small a dose as $\frac{1}{4}$ grain, hypodermatically, has produced great depression and collapse.

To the brain, then, cocaine is a powerful stimulant, first exciting, and in larger doses producing a narcotic state associated with convulsions of an epileptiform character. Upon the spinal cord the sensory portion is thought to be more responsive to cocaine than the motor tract, as toxic doses depress and paralyze the sensory nerves much more readily than the motor filaments. Upon the circulation its effects are less pronounced, arterial pressure being first increased, and if the dose be toxic, the pressure falls. That the heart substance or the intracardiac nerves are directly impressed, increasing the power of contraction, is thought to be the cause of the increased heart action. Striated muscles are not strongly impressed by cocaine, but it exerts a powerful stimulating effect upon the breathing organs, first increasing their action, and finally paralyzing the respiratory centers. While the urine is sometimes increased in quantity, diuresis is not a constant effect of the administration of cocaine, though nearly all agree in its power of decreasing urea-elimination.

Cocaine poisoning is best treated with amyl nitrite, though chloroform and ether (the latter subcutaneously) are useful. Alcohol, morphine, atropine, and chloral are also antidotes in some degree. The treatment is much the same as for poisoning by caffeine.

Medical Uses and Dosage.—Cocaine is not extensively used as an internal remedy. However, it may be given by mouth or hypodermatically, and has been found serviceable in the following conditions. In small doses it has proved a good heart tonic in low *febrile states*, but this use of it has received but little recognition from members of our school. In *angina pectoris*, however, while not so effective as amyl nitrite, nitroglycerin, or lobelia, doses of from $\frac{1}{4}$ to $\frac{1}{2}$ grain 3 or 4 times a day have given good results. When *dropsy* is due to heart debility, the same-sized doses 3 times a day, by their effect of causing increase or rise of blood pressure, stronger heart contractions, and a greater flow of urine, have accomplished cures. It is a remedy for the *vomiting of yellow fever*, *sea sickness*, and of *pregnancy*. In the latter condition it has also been applied by way of the rectum, or directly as an ointment to the os uteri. Testimony may be had for and against its use in *sea sickness*. As a preventative and as a remedy therefor, Monassein (*Med. News*, Vol. 47, p. 320), used a solution of cocaine hydrochlorate 0.15 part, alcohol a sufficiency, and distilled water 150 parts. A drachm dose of this was administered on embarking, and continued every 2 or 3 hours until no further danger of sickness seemed probable. In *sick headache* and *neuralgia* from $\frac{1}{4}$ to $\frac{1}{2}$ grain may be injected near the affected parts. The same may be resorted to in *sciatica*. The gloom of temporary *hypochondria* may be dispelled by small doses of cocaine, and fatigue due to loss of sleep may also be relieved by it. Its action in confirmed mental disorders, however, is deleterious, and it has failed to become a remedy for *neurasthenia*, *melancholia*, etc., as it was once hoped would prove to be the case. Were it not for the fact that almost toxic doses are required, it would be of value in such gastric disorders as *neuralgia*, *ulceration*, or *carcinoma* of that organ. As a remedy in the treatment of *alcoholism* and of the *opium habit* it has nothing to commend it, as a cocaine habit, as pernicious as those it is sought to cure, is extremely liable to become established.

Cocaine is locally used in a great variety of *painful affections* of the mucous tracts. When applied to the parts they become pale on account of the anemia resulting from the constriction of the vessels produced. It is thus valuable to arrest or to palliate *inflammation of the nasal membranes*, *fauces*, *pharynx*, and *larynx*. In acute *tonsillitis* a 2 to 4 per cent solution painted upon the parts relieves the pain and reduces the swelling, while for chronic cases a 6 per cent solution in a vehicle of one-third water and two-thirds glycerin is effective. These solutions should be painted upon the parts with a pencil twice a day. In *tubercular troubles* of the upper part of the throat, such as tenderness and ulceration, and in the irritable throat of *phthisis*, *cancer*, or *syphilis*, preventing the patient from taking food, a strong solution (6 per cent), applied to the parts 3 or 4 times a day gives marked relief, and enables the patient to take nourishment with comfort. Early applied it will arrest *coryza*, and applied in solution or suppository it is exceedingly effectual in the paroxysms of *hay fever*. Or it may be applied upon cotton wool or insufflated with some inert powder. It not only allays the pain and irritability, but it has a tendency to enlarge the nasal fossae through its constricting agency. It alleviates the painful condition of *fissures*, *ulcers*, etc., of the buccal membranes. *Epistaxis* may be arrested with cocaine locally applied. The solution is palliative only in *whooping-cough*, and may be used to allow the hydrophobic patient to swallow water and other fluids. Cocaine reduces *phimosis* and *paraphimosis*, and applied to the urethra or rectum controls *chordee*, and in enema or suppository is useful in allaying *cystic irritability* when due to an enlarged prostate, and will control *tenesmic pain* in the bladder or rectum. *Dysentery* is relieved by it locally applied, and in strong solution, suppository, or ointment, it mitigates the pain of *rectal cancer*. *Urethral spasms* are relaxed by it, and it relieves in the acute stage of *gonorrhœa*. It may be applied in itching and burning conditions of the vagina and anus. Applied to the vaginal orifice in cases of *vaginismus*, coitus may be perfectly and painlessly accomplished. A 2 per cent solution is valuable to assuage the pain of *burns* and *scalds*, and is of service in *wounds* of delicate parts like the eye, to subdue the exalted sensibility so that the

parts may be properly and painlessly dressed. Locally applied or subcutaneously injected, it subdues the pain incident to *insect stings* and *bites*. In *earache* from cold a few drops of equal parts of glycerin and a 2 per cent solution of cocaine arrests the pain. The same procedure may assuage the pain of *dental caries*.

Cocaine serves a valuable purpose in allaying irritability of parts so that examinations of delicate structures may be facilitated. It renders easy the use of the aural speculum, and instruments necessary in examination or operation upon the auditory canal, catheterization of the Eustachian tube, the introduction of the rhinoscope, laryngoscope, and lavage tubes, examination of the male or female urethra, and the introduction of catheters, bougies, or lithotrite, and the rectal speculum and dilators are all facilitated by first treating the parts with cocaine.

The discovery of the anæsthetic properties of cocaine revolutionized the practice of *minor surgical operations*, and especially upon the eye and kindred structures. As a local anæsthetic the acetate of cocaine was used as early as 1868, by Thomas Moreno y Maiz (*Paris Thesis*, p. 77); but the importance of this use of the drug did not seem to be fully appreciated by him. In 1880, Von Anrep called attention to the probable utility of cocaine as a local anæsthetic, but it was reserved for Koller, a student at Vienna, and now a practitioner of New York City, to perfect the knowledge of the anæsthetic uses of the drug and proclaim it to the world, and its success and popularity has been phenomenal.

In *ophthalmic surgery*, the solution generally employed is that of 4 per cent strength, though some use as high as an 8 to 10 per cent solution, but the latter has no particular advantage over the former. It should preferably be applied with a dropper at intervals of 3 or 4 minutes until 3 or 4 instillations have been made. Cocaine discs ($\frac{1}{4}$ grain) of gelatin, paper, linen, or cotton, are all undesirable and likely to become moldy. Not only does cocaine constricts the vessels of the part and produce local anæsthesia, but in the case of the eye it dilates the pupil and increases the power of absorption of atropine, homatropine, and eserine. A false astigmatism may be produced by its use on account of an irregular action set up in the ciliary muscles. The long-continued use of cocaine upon the structures of the eye is very deleterious, and following the temporary effects, inflammation of a grave character, ulceration, opacity, or exfoliation of the cornea having been produced by it. This is undoubtedly due to its constricting action, lessening the blood supply and consequently lowering the vitality of the tissues. Slow healing after operations has been attributed to the use of cocaine as an anæsthetic. In spite of its occasional bad results, however, it has become a most important agent with the ophthalmic surgeon. It is injected behind the eye for the removal of that organ, and should also be injected when operations upon the lachrymal sacs, incisions into the lachrymal canals, or operations upon the lids are to be performed. Its local use allays *photophobia*, and carried to anæsthesia by instillation it may be employed to remove *foreign bodies* from the eye, and in *operative measures* for *trachoma*, *pinguicula*, *pterygium*, *cauterization of corneal ulcers*, *strabismus*, *tenotomy*, *anterior staphyloma*, *iridectomy*, *cataract*, *prolapse of the iris*, the removal of *conjunctival* and *corneal growths*, and in other operations within or without the globe. As a rule it is contraindicated in glaucoma, but *hypopyon* is said to have been reduced in size by a 2 per cent solution.

In the nasal, pharyngeal, and laryngeal cavities it is employed to produce anæsthesia preparatory to the removal of *tumors*, *polypi*, and other *growths*, and to enlarge the parts in *nasal stenosis*, and to reduce *hypertrophied states of the mucous tract*. Operations for *harelip* and *cleft palate* have been performed under its use, while amputation of the *uvula* and *tonsils* are painlessly effected when the parts are well cocaineized. Operations for *hernia* and *staphylorrhaphy* have been successfully performed under cocaine anæsthesia. It should be used in opening *mammary abscesses*, *felons*, *suppurating bubos*, and for the removal of *ingrown nails*. While cocaine has been applied to sensitive teeth to facilitate their excavation, it is not considered universally applicable, and is not now very much used for that purpose. It is, however, very valuable, but not without occasional dangerous results, as an anæsthetic for the *extraction of teeth*, or of *alveolar spiculae*. The hydrochlorate is generally used, though some contend that better results are obtainable from the citrate. Of the 2 per cent solution 4 or 5 minims may be injected into the gum close to the tooth, and allowed to remain about 8 minutes before extraction

of the tooth is attempted. If it does not wholly control the pain it greatly lessens it, and especially obtunds the gum so that no pain whatever is felt in applying the forceps unless the gum be greatly inflamed.

Itching skin diseases, such as *eczema*, *herpes*, *erysipelas*, *scabies*, and the like are relieved by a 5 per cent petrolatum ointment of cocaine. The maximum dose of cocaine hydrochlorate should not be more than $\frac{1}{2}$, or at most, 1 grain, though some have put the limit at 2 grains, and the daily amount at 6 grains.

Specific Indications and Uses.—To produce local anæsthesia upon painful parts, or to facilitate examinations and minor operations upon sensitive tissues.

Other Salts of Cocaine and Related Drugs.—**COCAINE BENZOATE.** This salt forms needles which crystallize with difficulty. It is prepared by combining aqueous solutions of cocaine (5 parts) and benzoic acid (2 parts). Water freely dissolves it. *Benzoyl ecgonine* has been sold for it. The latter is formed by the action of water and heat upon cocaine.

COCAINE NITRATE.—Readily soluble, large crystals, devoid of color. It has been recommended as an agent to use conjointly with silver nitrate to lessen the pain caused by using the latter as a caustic. Cocaine hydrochlorate, however, can not be used with silver nitrate, owing to the formation of insoluble silver chloride.

COCAINE PHENATE.—A viscid, yellow mass soluble in alcohol, but not in water. On account of its being less readily absorbed, Von Oefele has proposed it for use in place of cocaine hydrochlorate as a local anæsthetic on mucous surfaces.

COCAINE BORATE contains 68.7 per cent of base. A white crystalline powder, soluble in alcohol, which solution is more permanent than that of cocaine hydrochlorate (Merck's *Index*, 1896).

COCAINE CITRATE forms a white crystalline powder, hygroscopic and soluble in water. It contains 75.7 per cent of cocaine. It is chiefly employed in dental practice. The dose is from $\frac{1}{16}$ to 1 grain.

COCAINE HYDROBROMATE ($C_{17}H_{21}NO_4 \cdot HBr$).—This salt occurs as small, white crystals (see Fig. 77). It is soluble in water, and is used in the same sized doses and for the same purposes as cocaine hydrochlorate.

EUCAINE.—Two preparations, viz., *Eucaïne "A"* and *Eucaïne "B"*, have recently been placed upon the market as substitutes for cocaine.

EUCAINE "A" (*n-methyl-benzoyltetramethyl-g-oxypiperidincarbonic acid-methylester*) is a white, crystalline powder, neutral, and soluble in 10 parts of water. It is claimed that it is less toxic than cocaine, though the maximum dose ($\frac{1}{2}$ grain) of the latter should not be exceeded. The solution does not, it is asserted, decompose, and may be sterilized without injury to the preparation. Claimed of less value for ocular work than the *Eucaïne "B"*, on account of the irritation and hyperemia produced. The following strengths of solutions are directed: Diseases of nose, throat, and ear, 2 to 8 per cent; dentistry, 4 to 9 per cent; minor surgical operations, 5 per cent; solutions of greater than 9 per cent strength deposit crystals of the drug.

EUCAINE "B" (*benzoylvinyldiacetonalkamine*) is crystalline, white, neutral, and soluble in 27 to 28 parts of water; hot water dissolves it more readily. Solutions non-decomposable and not affected by sterilization. Claimed to be slightly antibacterial, less toxic than *Eucaïne "A"*, and 5 times less poisonous than cocaine; does not cause mydriasis and corneal, or accommodation disturbances (as cloudiness of the cornea), but little vascular injection, etc. The strength of solutions recommended are: For ocular use, 2 per cent, about 4-drop instillations shortly before operations, prolonged and repeated applications producing untoward effects; infiltration anæsthesia, $\frac{1}{4}$ to 1 per cent; genito-urinary disorders, $\frac{1}{4}$ to 2 per cent.

Though conceded to be less toxic than cocaine, eucaine is reported to have produced intoxication through the application of 4 per cent solutions to the throat. F. B. Kellogg, M. D., Tacoma, Wash. (*Pacific Coast Journal of Homœopathy*, April, 1897), reports such a case exhibiting "spasmodic muscular contractions of the arms and legs;" "the heart's action was also affected, the pulse becoming rapid and small." Dr. Kellogg regards eucaine as too irritating for ordinary application to the eye. The greatest advantage, he concedes, is its value when desirable to avoid pupillary dilatation, as in the removal of *foreign bodies* (the iris acting as a back ground in light-colored eyes, thus aiding in the detection of the particle), and for use upon the eyes of the elderly with "*glaucomatous tendency*." It gives one advantage in *nasal operations*, in that, by not causing shrinkage, it allows the operator to ensnare *posterior hypertrophies of the inferior turbinated bone*, being useful as well in *anterior hypertrophies*. On the other hand, cocaine produces a marked shrinkage of the tissues. As yet the exact therapeutical position of the agent can not be stated.

TROPA-COCAINE.—Tropa-cocaine, an alkaloid isolated by Giesel from the narrow-leaved variety of *Erythroxylon* (oca, Lamarek, grown in Java, is, according to Liebermann, *benzoyl-pseudo-tropine* ($C_{21}H_{27}NO_4 \cdot C_6H_5 \cdot CO$) (see *Cocaine*). It is also prepared synthetically. The hydrochlorate is principally used. It occurs in colorless crystals, soluble in water, the solution being (claimed) more stable than the corresponding solution of cocaine hydrochlorate. It is reputed a local anæsthetic, differing in action from cocaine and other local anæsthetics in not producing irritation, hyperemia (occasionally slight and transient hyperemia), or ischemia; furthermore it is said to be less toxic and depressing to the cardiac ganglia and to the heart. But little or no mydriasis results from its use. Anæsthesia is quickly produced, according to Silex, *tenotomy* having been painlessly performed in less than $\frac{1}{4}$ minute after the application of a 3 per cent solution of the hydrochlorate. The usual method of exhibition is the 3 per cent solution of tropa-cocaine, in a 0.6 per cent sodium chloride solution, 1 or 2 drops being instilled into the eye.

COCCUS (U. S. P.)—COCHINEAL.

"The dried female of *Coccus cacti*, Linné"—(U. S. P.).

"Class: Insecta. Order: Hemiptera"—(U. S. P.).

Source.—The cochineal insect, *Coccus cacti*, belongs to the class Insecta, order Hemiptera; the general characters are: Tarsi, with one joint, terminated by a single hook. The male is destitute of a rostrum, and has two wings covering the body horizontally; the abdomen is terminated by 2 setæ. The female is apterous, and furnished with a rostrum. The antennæ are of 11 joints, filiform, and setaceous. The males are very small, with antennæ shorter than the body, which is elongated, deep-red, and terminated by 2 long, diverging setæ. The wings are beautifully snow-white, large, and crossed above the abdomen. The females are nearly twice as large as the males, wingless, bluish-red, covered with a white farina, have the antennæ short, and the body convex and flattened below, with short feet.

History.—The Cochineal insects inhabit Mexico, and other parts of tropical America, where they feed on the *Opuntia* and *Cactus* families of plants. They are also cultivated extensively in the Canary Islands, and to some extent in the West Indies, and have been introduced into southern Spain, though their cultivation in the latter country is said to have been unprofitable. They are collected at various seasons. The best are the product of the first collection, which consists of the impregnated females; the males not being gathered. Those killed by the heat of a stove are said to be superior to those destroyed by boiling water and sun-dried.

The insects are protected during the rainy season by coverings placed over the cactus plants on which they are feeding. After pleasant weather has returned they are taken out and planted or sown on the different species of *Opuntia*, particularly the *Opuntia cochinillifera* of Miller, known to the Mexican natives as *nopal*. The male insect, which is very rapid in its movements, flies to the female, and, after the act of fecundation, the female attaches itself to the plant and remains stationary, rapidly enlarging from the development of an immense number of eggs within the body, and, in this distorted condition is knocked off the plant with feathers and dull knives, and either dipped into hot water and afterwards sun-dried, or killed by being placed in heated ovens. A few are left, however, to deposit their eggs, shortly after which they die. The eggs, hatching in the sun, give an innumerable supply of young insects, which at once distribute themselves over the plant and begin feeding. In this manner 3 crops are gathered yearly from the *nopal plantations*. For a full and instructive account of the cultivation of cochineal in Central America, see *Amer. Jour. Pharm.*, 1873, p. 30.

Description.—The U. S. P. thus describes cochineal: "About 5 Mm. ($\frac{1}{4}$ inch) long; of a purplish-gray or purplish-black color; somewhat oblong and angular in outline; flat or concave beneath; convex above; transversely wrinkled; easily pulverizable, yielding a dark-red powder. Odor faint; taste slightly bitterish. Cochineal contains a red coloring matter soluble in water, alcohol, or water of ammonia, slightly soluble in ether, insoluble in fixed and volatile oils. On macerating cochineal in water it swells up, but no insoluble powder should be separated. When completely incinerated, cochineal should leave not more than 5 per cent of ash"—(U. S. P.). As met in commerce, cochineal is sometimes covered with a white bloom, which, if not due to adulteration, consists of a wax-like body (see below). When properly kept it is not liable to deteriorate. There are two varieties, *silver grains* (*silver*, or *Honduras cochineal*) and *black grains* (*zaccatilla*

Fig. 79.

Coccus cacti.

1. Cochineal insects feeding.
2. Female insect.
3. Male insect.

cochineal). The silver cochineal, of a reddish ash-color, is said to be procured by destroying the female insect previous to laying its eggs, and is the most esteemed; the black cochineal, of nearly a black color, is obtained by killing the female after the eggs have been laid (*Amer. Jour. Pharm.*, Vol. XVIII, p. 47). According to other statements the silver grains are the product of oven-killed insects, or those allowed to perish by sun-heat, while the black grains are produced by immersion of the live insect in boiling water. There are also inferior grades, consisting chiefly of uncultivated young insects, called *granilla* (*grana sylvestra*). Dr. Jas. Stark, in 1855, directed attention to a commercial form, called "cake cochineal," imported from Cordova, Argentine Republic. However, it possessed only $\frac{1}{2}$ of the coloring strength of ordinary cochineal.

Chemical Composition.—Cochineal imparts a violet-red tinge to the saliva. It was first analyzed by Pelletier and Caventou, in 1818, and according to Hager (*Handbuch*, 1886), was found by subsequent analyses to contain moisture (about 6 per cent), fatty matter (15 to 18 per cent), red coloring matter (40 to 45 per cent), ash (3.5 to 5 per cent), and insoluble matter (7 to 11 per cent). The red coloring matter, first investigated closely by Warren de la Rue, in 1847, has been called *carminic acid*, and, following the later researches of Grabowski and Hlasiwetz, was believed to be a glucosid capable of being resolved by the action of diluted sulphuric acid, into *carmine-red* and sugar. Von Miller and Rohde (1893), however, established the non-glucosidal character of this substance. Pure carminic acid, by treatment with boiling dilute sulphuric acid, remained on the whole unaffected, although partial decomposition took place, yielding formic acid and a strongly reducing substance of unknown composition (*Amer. Jour. Pharm.*, 1894; from *Berichte*, 1893). According to Liebermann and Voswinkel (1897), carminic acid yields upon oxidation *cochenillic acid* ($C_{10}H_6O_7$) and *coccinic acid* ($C_8H_6O_5$) which are (tri- and dicarboxyl) derivatives of *meta kresol* ($C_6H_4CH_2OH$). The exact structural formula of carminic acid is not exactly established.

Carminic acid (*carmine-red*) usually occurs as a brown-purple body, but may be obtained in large, garnet-red crystals by treating good commercial cochineal with 5 times its weight of water, filtering, agitating with 20 times its weight of glacial acetic acid, filtering again, and allowing the solution to crystallize over sulphuric acid (v. Muller and Rohde). Carminic acid is soluble in alkalis, warm water, and alcohol; not soluble in oils and fats; aluminum salts precipitate it in the form of a purple-lake. Will and Leymann obtained from 5 kilograms of the silver-gray variety of cochineal, 400 to 500 grammes of pure carmine-red. These investigators also obtained two bromine compounds ($C_{22}H_8Br_2O_8$ and $C_{11}H_4Br_2O_4$), which are mainly of theoretical interest (see *Amer. Jour. Pharm.*, 1886, p. 91). The whitish material covering the insect was investigated by Liebermann (1885), who found it to be a peculiar wax, soluble in benzol, which he named *coccerin*, the constituents of which are *coccerylic acid* ($C_{21}H_{32}O_8$), melting at about $92^\circ C.$ ($197.6^\circ F.$), and *cocceryl alcohol* ($C_{20}H_{32}O_7$), melting at about $104^\circ C.$ ($239.2^\circ F.$). Besides, he found in cochineal *myristin* (1.5 to 2 per cent), and liquid fatty oil (4 to 6 per cent). Liebermann observed 1 to 2 per cent of coccerin in the silver variety, 0.5 to 1 per cent in the black variety, while from *granilla* (the inferior kind) he obtained 4.2 per cent (*Amer. Jour. Pharm.*, 1886).

Adulterations.—*Carmine* has been adulterated largely with starch, vermilion, dichromate of lead, talcum, etc. These additions, however, may be readily detected by dissolving the cochineal coloring matter with aqua ammoniæ, and examining the residue for the substances named. E. Donath, in *Chem. Zig.*, 1891, reports on a sample of commercial "ordinary" carmine, which consisted of lead oxide and alumina lakes of *eosine*, and contained much lead sulphate. Another specimen ("carmin antik") of good appearance was the barium compound of *red corallin* (related to rosolic acid and rosanilin), leaving, upon ignition, 75 per cent of barium carbonate (*Amer. Jour. Pharm.*).

Cochineal, especially in powder form, has been adulterated with French chalks, plumbago, soapstone, carbonate of lead, manganese dioxide, barium and iron salts, etc., to increase the weight, and the grains have even been imitated. The U. S. P., as stated before, fixes the upper limit of ash at 5 per cent. We, however, have found the majority of commercial specimens (both powdered and whole cochineal) to exceed this limit by far, the ash often running as high as 25 and 32 per

cent. A species of *Coccus* (*Coccus ilicis*, Fabricius, feeding upon a Mediterranean oak (*Quercus coccifera*, Linné), has been occasionally met as an adulteration. It is known as *cherries*, *kermes*, or *alkermes*, and, when dried in the sun after having been treated with acetic acid, becomes colored a brown-red, and yields a carmine powder, producing with tin salt ($\text{SnCl}_2 + 2\text{H}_2\text{O}$) a bright scarlet-red color, similar to that derived from true coccus. They are nearly spherical and quite smooth.

Action, Medical Uses, and Dosage.—Anodyne and antispasmodic. Formerly used in *whooping-cough* and *neuralgic affections*. Also used to color tinctures and ointments, imparting a beautiful carmine hue. Webster (*Dynam. Therap.*, p. 431) declares that coccus specifically influences the entire urinary tract and directs small doses in *renal colic*, *copious voidings of clear, limpid urine*, due to renal capillary relaxation, and in *vesical tenesmus* and *urinal retention*. He suggests that 10 to 15 drops of mother tincture be added to 4 fluid ounces of water, and a teaspoonful administered every 2 hours. Dose, from 5 to 10 grains, 3 or 4 times a day.

Specific Indications and Uses.—“*Colica renalis*, with dark-colored urine and pain extending down ureters to bladder” (Watkins’ *Comp. of Ec. Med.*).

Derivative.—**CARMIN** (derived from cochineal) is not a definite principle, but contains a mixture of nitrogenous compounds, ash, wax, and coloring matter to the extent of as high as 60 per cent. It may be prepared by precipitating a filtered cochineal decoction with bitartrate of potassium or alum, and collecting and drying the precipitate at about 30°C . (86°F .).

RED INK.—Red ink may be made as follows: Take of cochineal in powder, 160 grains; carbonate of potassium, 320 grains; distilled water, 8 fluid ounces; mix together and boil; then add of alum, 80 grains; bitartrate of potassium, 2 ounces; let them stand for 24 hours, filter, and add $\frac{1}{2}$ ounce of powdered gum Arabic.

CODEINA (U. S. P.)—CODEINE.

FORMULA: $\text{C}_{18}\text{H}_{21}\text{NO}_3 + \text{H}_2\text{O}$. **MOLECULAR WEIGHT:** 316.31.

SYNONYMS: *Codeinum*, *Codeia*, *Methyl morphine*.

“An alkaloid obtained from opium”—(U. S. P.).

Source and History.—Codeine, one of the alkaloidal constituents of opium, exists therein in the form of *meconate*. It was discovered in 1832, by Robiquet, and its close chemical relation to morphine ($\text{C}_{17}\text{H}_{19}\text{NO}_3$), was pointed out by Matthiessen and Wright, in 1869, who demonstrated that *codeine* ($\text{C}_{18}\text{H}_{21}\text{NO}_3$) must be considered as *methyl morphine*. In 1881, Grimaux succeeded in preparing codeine synthetically from morphine by heating together equimolecular quantities of methyl iodide (CH_3I), morphine and sodium hydrate in alcoholic solution. O. Hesse also effected the synthesis of codeine from morphine independently of Grimaux’s discovery, and further methods have since been elaborated by A. Knoll and others.

Preparation.—Directions for preparing codeine from opium are given by Hager (*Handbuch*, 1886). According to this process the hydrochlorates of morphine and codeine, after being obtained together, are decomposed by caustic potash solution, whereby codeine is precipitated, while morphine remains in solution. In the process of Robiquet and Anderson these alkaloids are separated by means of aqua ammoniæ which precipitates the greater part of the morphine, while codeine hydrochlorate remains dissolved, crystallizing upon concentration of the liquid. From this salt the codeine is liberated by caustic potash, and purified (see also *Codeina* under *Opium*).

Description.—“White, or nearly translucent, orthorhombic prisms, or octohedral crystals, odorless, having a faintly bitter taste, and slightly efflorescent in warm air. Soluble at 15°C . (59°F .), in 80 parts of water and in 3 parts of alcohol. In boiling water codeine melts into oily drops which dissolve in 17 parts of the water. It is very soluble in boiling alcohol; also soluble in 30 parts of ether, and in 2 parts of chloroform. At 100°C . (212°F .), codeine loses its water of crystallization (5.67 per cent); at 155°C . (311°F .) it melts, forming a colorless liquid; and when ignited it is consumed without leaving a residue. Codeine is neutral to litmus paper”—(U. S. P.)

Codeine, the reverse of morphine, is almost insoluble in concentrated solutions of caustic soda or potassa. In ammonia water codeine is soluble in the proportion of about 1 to 85, and morphine 1 to 117. Codeine is also soluble in carbon

disulphide, and methylic and amylic alcohol. Recently, M. L. Fouquet suggested a method of separating codeine from morphine, based on the difference of solubility of these alkaloids in *anisol* (the methyl ether of phenol [$C_6H_5OCH_3$], boiling point $150^{\circ} C.$ ($302^{\circ} F.$), and sp. g. 0.991), morphine being insoluble and codeine soluble in this liquid at ordinary temperature (*Amer. Jour. Pharm.*, 1897, p. 158). From absolute ether, codeine crystallizes without water of crystallization. With acids it forms crystallizable salts, nearly insoluble in ether. Codeine is so strong a base that it displaces morphine from its salts.

Tests.—"If 0.1 Gm. of codeine be dissolved in 6 Cc. of cold, concentrated sulphuric acid (free from nitrose), the resulting liquid should be colorless. If about 2 Cc. of this solution be poured into a small porcelain capsule, and 1 drop of highly diluted nitric acid (made by adding 1 drop of nitric acid to 200 Cc. of water) added, a bluish-red tint gradually changing to pale blue will be developed. Another portion of the same solution, of about 2 Cc., gently warmed and mixed with 1 drop of a mixture of 1 volume of ferric chloride T.S. and 19 volumes of water, likewise assumes a bluish or blue tint (difference from morphine). On adding to 5 Cc. of an aqueous solution of codeine (1 in 100), 10 drops of bromine water, and shaking so as to redissolve the precipitate formed, the liquid will gradually develop a light claret-red tint. This tint may be developed at once by the addition of ammonia water. On sprinkling 0.05 Gm. of codeine upon 2 Cc. of nitric acid (specific gravity 1.200), the crystals will turn red, but the acid, even when warmed, will acquire only a yellow color (difference from and absence of morphine)"—(*U. S. P.*).

Unlike morphine, codeine does not liberate iodine from iodic acid. *Fröhde's Reagent* (a solution of 1 gram of sodium molybdate in 1 liter of water), dissolves codeine with a dirty-green color which soon turns blue, fading to yellow only after many hours. A characteristic test for codeine is that proposed by L. Raby, which, according to the *Amer. Jour. Pharm.*, 1886, p. 495 (from *Jour. Pharm. Chim.*, 1884), is executed as follows: Rub a small quantity of codeine with 2 drops of a solution of sodium hypochlorite on a watch crystal, and add 4 drops of concentrated sulphuric acid. A beautiful sky-blue color is then produced. No other alkaloid is known to produce the same reaction.

Action, Medical Uses, and Dosage.—Codeine acts specifically upon the *vagus*. When pure it is probable that large doses of it may be taken without decided physiological effects. However, that is denied by some investigators. That the commercial product varies greatly is generally accepted, and by the majority of observers the effects of commercial codeine are mainly attributed to its impurities, the adherent alkaloidal bases. Owing to its great variability the smaller amounts should always be given as a beginning dose and the drug increased until its desired action is obtained. While as high as 8 grains have been given in 24 hours without pronounced effects, 4 grains have, in another instance, caused almost fatal results (*Myrtle, Br. Med. Jour.*, 1874). Among the effects of codeine are the following: Small doses of $\frac{1}{4}$ grain seldom occasion constipation, nausea, or vomiting, but produce a calmative effect, followed by a peaceful and refreshing slumber, without producing skin eruptions or perspiration. Large doses, from $1\frac{1}{2}$ to 2 grains, produce first a sense of exhilaration, quickly followed by depression with nausea, vomiting, anxiety, giddiness, tremor, dullness of intellect, cerebral fullness and heaviness, and cold, pale, and moist skin. The pulse is slightly quickened, the pupils somewhat contracted, and delirious wakefulness is added to the unpleasantness.

Codeine in $\frac{1}{4}$ -grain doses, increasing as indicated, has been used in the treatment of the *opium habit*—being a substitute for the latter agent and the morphine salts. It was introduced into medicine chiefly on account of its beneficial effects in *diabetes*, both simple and saccharine. Much evidence has been produced to show that it lessens both the amount of urine secreted and the quantity of glucose produced. However, it has not by any means proved of universal application in these disorders. Large quantities of codeine are used in France as a calmative to take the place of opium, to which it is inferior in power, and over which it has the advantage of being, in ordinary doses, practically non-constipating. It is a favorite with some as a calmative in *restlessness* and *insomnia*, and as a quieting agent in *cough*, and particularly that of *phthisis*, being employed where opium is

not well tolerated, and is regarded as superior to the latter from the fact that it does not irritate the stomach, nor disorder digestion. In doses of from $\frac{1}{4}$ to 1 grain, it is anodyne and antispasmodic, without acting as a soporific. For this purpose it has been employed in *painful abdominal disorders*, as *enteralgia*, and in *painful diseases of the genito-urinary tract*, in pain due to structural disease or to obstructions, and as a remedy for *neuralgic*, *rheumatic*, and various *paroxysmal pains*. It is especially adapted for the relief of mild pain from ovarian irritation.

Although inferior to morphine for allaying pain, and necessarily given in larger doses, in many respects it is superior to it in its effects, never causing heavy agitated sleep, perspirations, eruptions of the skin, obstinate constipation, retching, vomiting, nor disturbance of digestion when given in the smaller doses. Its earlier application was in *nervous diseases of the stomach*, in the stubborn and harrassing coughs of *bronchitis* and *consumption*, in violent *rheumatic* and *gouty pains*, and in the *pains of cancer*.

The beginning dose of codeine is $\frac{1}{4}$ grain, increased as indicated, and may be administered in powder, pill, or syrupy mixtures. The sulphate and hydrochlorate are given for similar purposes and in like doses, while the phosphate, in doses of about $\frac{1}{4}$ to $\frac{1}{2}$ grain, may be given hypodermatically.

Specific Indications and Uses.—A calnative where opium is apparently indicated, but not well tolerated. Insomnia, and particularly when sleep is prevented by cough; cough, constant and irritating; abdominal pain; diabetes.

Related Salt.—CODEINE PHOSPHATE is official in the *German Pharmacopœia*, which demands that this product when heated to 100° C., should lose about 8 per cent of its weight. The salt forms white needles of bitter taste, quite soluble in water, less so in alcohol. It is obtained by neutralizing codeine with phosphoric acid and crystallizing from water, or precipitating the solution with alcohol. Prof. E. Schmidt has demonstrated that under these conditions a salt of the composition $C_{18}H_{21}NO_3 \cdot H_3PO_4 + 2H_2O$ results, while, when crystallized from hot dilute alcohol its composition is represented by the formula $2(C_{18}H_{21}NO_3 \cdot H_3PO_4) + H_2O$ (*Amer. Jour. Pharm.*, 1890, p. 445).

Derivatives.—APOCODEINE ($C_{18}H_{21}NO_3$). Matthiessen and Wright obtained this body by heating codeine hydrochlorate with zinc chloride in excess to a temperature of 180° C. (356° F.). More recently, W. Göhlich produced the same substance by acting with alcoholic caustic potash under pressure upon *chlorocodin* ($C_{18}H_{21}ClNO_3$), a chlorine substitution product of codeine (see *Archiv. der Pharm.*, 1893, pp. 235-290). Apocodeine is an amorphous mass, soluble in alcohol, chloroform, and ether, and acts as an emetic and expectorant like apomorphine, being more stable than the latter body. A perfectly neutral solution may be used hypodermatically. The dose is about $\frac{1}{4}$ grain. Large doses may produce death, preceded by emesis and coma.

PSEUDO-CODEINE ($C_{18}H_{21}NO_3 + H_2O$).—Merck, in 1890, obtained this body as a by-product in the manufacture of apocodeine, and proved it to be an isomer of codeine. W. Göhlich (*Archiv. der Pharm.*, 1893) demonstrated its being identical with a crystallizable body which he obtained by heating codeine with a mixture of an equal volume of sulphuric acid and water. The amorphous form of this substance Göhlich found to be identical with the "amorphous codeine" of Armstrong, the melting point of these bodies being 180° C. (356° F.). Kobert states that the physiological effects of pseudo-codeine are similar to those of codeine.

COLCHICUM.—COLCHICUM.

The corm and seeds of *Colchicum autumnale*, Linné.

Nat. Ord.—Liliaceæ.

COMMON NAME: *Meadow saffron*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 287.

Botanical Source.—This plant has a large, ovate, solid, fleshy corm (tuber, according to some authors). The leaves are dark-green, very smooth, obtuse, above a foot long, $1\frac{1}{2}$ inches broad, keeled, and produced in the spring along with the capsules. The flowers are several, radical, leafless, and bright purple, with a long, white tube appearing in the autumn without the leaves. The capsules 3 and distinct, though forming together a single, oblong, elliptical fruit, with intermediate fissures. The seeds are whitish and polished (L.).

History.—*Colchicum* grows in meadows and low, rich soils in many parts of Europe, and is common to England. The herb is annual, but the bulb is annual or perennial, according to the manner in which the plant is propagated, which may be from the seed, by the formation of a single mature bulb from a parent bulb, or by the separation of several immature bulbs from the parent. A brief

reference to its mode of development may be useful: "In June or July a new bulb about the size of a grain of wheat is formed at the lower end of the old one, in close approximation with its radicles; this little bulb increases with rapidity, and at the same time sends up a leafless flower-stem. Toward the first of October a lilac, or pale-purple, flower springs from the ground, the germen remaining at the base of the corolla tube, but the leaves do not appear until early in the ensuing spring, at which time the germen, consisting of 3 many-seeded capsules, is elevated, and the seeds are matured during midsummer, after which the plant speedily withers. While the flower is rising in the autumn, the bulb is very small, but in the winter it grows rapidly, being in April as large as a chestnut, and attaining its greatest size, about that of a small apricot, in July. It is now a year old, and the herb having matured its seed, is withering away, but a new bulb appears at the lower end, close to its junction with the radicles or root proper, and passes through a similar succession of changes; while the old parent bulb gradually becomes more spongy and watery, but retains its size until the following April, the second spring of its own existence, when it quickly decays" (C.).

FIG. 80.
Colchicum autumnale.

Description.—**COLCHICI RADIX** (U. S. P.), *Colchicum root*. "About 25 Mm. (1 inch) long, ovoid, flattish, and with a groove on one side; externally brownish and wrinkled; internally white and solid; often in transverse slices, reniform in shape, and, breaking with a short, mealy fracture; inodorous; taste sweetish, bitter, and somewhat acrid"—(U. S. P.).

COLCHICI SEMEN (U. S. P.), *Colchicum seed*.—"Subglobular, about 2 Mm. ($\frac{1}{16}$ inch) thick, very slightly pointed at the hilum; reddish-brown, finely pitted, internally whitish; very hard and tough; inodorous; taste bitter and somewhat acrid"—(U. S. P.).

The seeds and the bulb are the official parts of the plant. The bulbs are usually collected about the beginning of July, but are said to attain their greatest perfection while the plant is flowering, or just after blossoming, at which time colchicum should be gathered for medicinal use. The odor is hircine (stinking like a goat), and the taste bitter, acrid, and nauseous. In drying, the bulb is usually cut into thin transverse slices, having first been stripped of its external dark brownish-black membranous tegument, and is dried quickly; sometimes it is dried entire. Good colchicum bulbs, when dried, are capable of changing their color to blue if softened with distilled vinegar, and then touched with tincture of guaiacum. Stained or mouldy bulbs should be rejected. Their virtues are imparted to alcohol, vinegar, or wine. The acetic tincture is often preferred to the vinous, as it is not so liable to change or decomposition. Acids render the vinous tincture drastic, while alkalies render its operation milder. The decoction of the fresh bulb forms, with a solution of iodine, a deep-blue precipitate (iodide of starch); with perchloride of iron, a faint bluish tint (gallate of iron); with subacetate of lead, or mercurous nitrate, a copious white precipitate; with nitrate of silver, a white precipitate, which soon becomes black; with tannin, a very slight, dirty-looking precipitate; and with a solution of gelatin, a slight haziness (P.). It was formerly supposed that the medicinal virtues of the seeds resided in the husk or cortical part, and it was advised not to bruise them in making the tincture, but experiments have proved that the bruised seeds yield the strongest tincture. Their properties are similar with those of the bulb, and, as they are considered more uniform in strength than the bulb, they are usually preferred.

Chemical Composition.—Of general plant constituents, colchicum bulbs contain gum, starch (more than one-fourth their weight), sugar, resin, tannin, and water (as high as 70 per cent). A volatile principle present in the fresh bulb, and to which its odor is due, is dissipated in drying. Fatty oil occurs in the seeds; Flückiger found 6.6 per cent, Rosenwasser 8.4 per cent. The peculiar constituent, common to all parts of the plant (bulbs, seeds, and flowers), is *colchicine*, concerning which there has been much discussion. Pelletier and Caventou (1820) thought it identical with veratrine, but Geiger and Hesse demonstrated it to be different. These and other investigators, however, describe it as a crystallizable body, but colchicine, as now established through the researches of Aschoff,

Bley, Oberlin, Hübler, Maisch, Hertel, and Zeisel, can not be obtained in crystalline form. Oberlin, in 1856, made the discovery that, by evaporation of an acidulated solution of colchicine, a crystallizable body is formed, to which he affixed the name *colchicéine*. This is most probably the substance described by the earlier chemists. Hübler, in 1865, arrived at the conclusion that colchicine and colchicéine were isomeric bodies, which was proved erroneous by the more recent investigations of Zeisel.

Hertel, in 1881, gave a process for the extraction of colchicine from the seeds, by which he obtained 0.4 per cent of pure colchicine. Aschoff had previously obtained about 0.2 per cent from seeds and 0.085 per cent from the bulb. Hertel also investigated the resinous coloring matter accompanying colchicine, to which he gave the name *colchico-resin*. He found it to be a decomposition product of colchicine due to exposure to the air, or to higher temperature, in a moist condition. He found it especially in the dead leaves surrounding the tubers, and in dried seeds and tubers. *Beta-colchico-resin* he observed in the process of making colchicéine from colchicine by means of diluted hydrochloric acid. Houdès, in 1885, concluded that he obtained crystallized colchicine, a point that S. Zeisel had, however, cleared, in 1883, by demonstrating that colchicine crystallizes from chloroformic solutions in the form of a chloroform compound. To Zeisel and Johanny (1888) is finally due the credit of having established the accurate formulæ for colchicine and colchicéine, and the chemical relationship the substances bear to each other.

Colchicine ($C_{27}H_{45}NO_6$, or $C_{27}H_{45}[OCH_3]_2.NHCH_2.CO.COOCCH_3$) is the methyl-ester of *colchicéine* ($2C_{27}H_{45}NO_6 + H_2O$, or $C_{27}H_{45}[OCH_3]_2.NHCH_2.CO.COOH$), the latter (crystallizable) body being formed by heating colchicine with dilute mineral acids, whereby methyl alcohol is split off. The question whether colchicine is an alkaloid, has been much debated. It is certain, however, that colchicine has weak basic properties, and yields precipitates with some alkaloidal reagents, yet, as a rule, it does not combine with acids to form a salt. Zeisel succeeded in establishing an exception by forming a double salt with gold chloride. Zeisel's colchicine melts at $143^\circ C.$ ($282.6^\circ F.$). Hertel describes *colchicine* as a sulphur-yellow body, impossible to crystallize, possessing a very slight alkaline reaction, but very indifferent body, the only noteworthy and insoluble compound being that with tannic acid. Colchicine is soluble in water, alcohol, and chloroform, hardly soluble in ether and benzol. Nitric acid has been recommended as the best reagent for the detection of colchicine, yielding a violet coloration. A mixture of nitric and sulphuric acids produces a series of colors changing from green to dark blue, violet and yellow (*Amer. Jour. Pharm.*, 1888, p. 569).

Colchicéine is described by Hertel as occurring in white and odorless crystals, readily soluble in alcohol, chloroform, and caustic potash, with yellow color; the fusing point is $150^\circ C.$ ($298^\circ F.$). With ferric chloride it yields a beautiful green coloration even in greatly diluted solution. The alcoholic solution feebly reddens litmus. Zeisel states that it has the double character of a weak base and an acid, which behavior its formula sufficiently explains. Like colchicine, it forms a double salt with gold chloride. Hübler, on the other hand, has prepared salts of colchicéine with bases. With the exception of the salts with alkalies, these compounds are insoluble in water, but soluble in alcohol and chloroform.

Apocolchicéine was obtained by Zeisel (1883) by heating colchicéine with diluted hydrochloric acid, methyl chloride being disengaged in the reaction. It has both basic and acid properties, and was first observed as a by-product, and obtained from colchicine in the preparation of colchicéine. H. Warnecke found in colchicum seeds 2.66 per cent of ash.

Action, Medical Uses, and Dosage.—Colchicum in small doses is stimulant, increasing the secretions of the skin, kidneys, liver, and bowels. Epigastric heat, eructations, and a sense of nausea accompany the administration of a large dose or several moderate doses. If the medicine be continued a coated tongue, anorexia, colicky pains, intestinal gurgling, and diarrhoea may result. Large doses occasion bilious vomiting, colic, tenesmus, and bloody mucoid evacuations, accompanied with anal heat. Toxic doses act as an acronarcotic poison, producing violent gastro-intestinal symptoms much like those of cholera—headache, vomiting, griping pain in the bowels, diarrhoea, painful cramps of the muscles

and feet, collapse, decreased circulation, and death, probably from cardiac syncope. Colchicine is a powerful poison, and should rarely be used. Medicinally, colchicum is sedative, cathartic, diuretic, and emetic. Used in *gout* and *gouty rheumatism*, *dropsy*, *palpitation of the heart*, *gonorrhœa*, *enlarged prostate*, etc. Care must be had in its employment. It sometimes increases the uric acid in the urine of arthritic patients; and has been beneficially employed in *febrile*, *inflammatory*, and *nervous affections*, and in *chronic bronchial complaints*. Equal parts of tincture of colchicum and laudanum have been found efficient in some cases of *gonorrhœa*. The reputation of colchicum rests most largely upon its value in *gout* and the conditions hinging upon a gouty diathesis. It is, perhaps, better adapted to acute than chronic gout. By its eliminative powers it removes from the system the morbid material upon which the gout depends. As a rule many of the failures to remedy this condition have been due to the fact that too large doses of colchicum have been employed. The dose will vary, however, some cases requiring larger doses than others, but in all cases the administration should be short of producing a free action from the bowels, the best effects being obtained from its slow and silent action. As a remedy for *rheumatism* it has been less employed. In *cardiac rheumatism* it may be alternated with the alkalies where the latter are indicated. The wine of colchicum may be given in 10-drop doses, or drop doses of specific colchicum may be given every 4 hours. As a rheumatism remedy it acts equally well in the acute and chronic conditions, provided the temperature and pulse be first brought almost to normal by means of other agents. Tearing muscular pain is the indication for it. It is efficient in *rheumatic iritis* and in *chronic rheumatism* when there is effusion into the joints and tearing pain aggravated by heat, and the joints present a swollen condition. *Dysmenorrhœa* and *hepatic enlargements* are also remedied by it when associated with a *gouty diathesis*. Large doses should never be used, and the action of the drug should always be carefully watched. Prof. Scudder employed small doses for *intestinal disturbances* with gaseous accumulation, as in *colic* from intestinal irritation. It has been used in *subacute* and *chronic sciatica* where the pain is "sharp-shooting, tearing, or dull-aching" from back to hip and down the leg, fever being absent. "It is not the kind of pain so much as its position" (Dr. L. A. Kelley).

A good acetic tincture may be made by macerating 1½ ounces of the dried bulb, or seeds, in 12 fluid ounces of the strongest vinegar for 14 days. Then filter and keep in well-stoppered bottles. The dose for an adult is from 10 to 60 drops as often as may be required. An acetic extract may be prepared, containing all the powers of the plant, by rubbing the fresh bulbs to a pulp to the quantity of a pound, and gradually adding acetic acid, 3 fluid ounces. Express the liquid, and evaporate it in an earthen vessel not glazed with lead, to the proper consistence; the dose is from 1 to 3 grains, 3 or 4 times a day. Dose of the dried bulb, from 1 to 10 grains, gradually increased every 4 or 6 hours, till the influence of the medicine is obtained. Wine of colchicum, 10 to 20 drops; English wine of colchicum, 5 to 10 drops; tincture of root, 10 to 60 drops; tincture of seed, 10 to 40 drops; specific colchicum 1 to 10 drops; colchicine, 1½ grain twice a day.

Specific Indications and Uses.—Gout; gouty diathesis; rheumatism, pain tearing and aggravated by heat, to be used after sedation has been accomplished; pain in course of the nerves; gouty headaches with swellings of joints, constipation, and nervousness; sudden tearing pain from back to hip, and down limbs, without fever.

COLLINSONIA.—STONE-ROOT.

The fresh root and plant *Collinsonia canadensis*, Linné

Nat. Ord.—Labiæ.

COMMON NAMES: *Stone-root*, *Rich-weed*, *Rich-leaf*, *Knob-weed*, *Knob-root*, *Horse-balm*, *Horse-weed*, and improperly as *Hardhack* and *Heal-all*.

ILLUSTRATIONS: Meehan's *Native Flowers and Ferns*, II, 165; Millspaugh's *American Medicinal Plants*, Pl. 119.

Botanical Source.—Collinsonia is a perennial herb, having a square stem, smooth, or slightly pubescent, somewhat branching at the top, and growing from 2 to 4 feet high. The leaves are large, coarsely serrated, ovate, acuminate, lower

ones petiolate, upper ones nearly sessile. The flowers, appearing in summer and early fall, are greenish-yellow, and are arranged in a terminal paniculate raceme. The corolla, funnel-shaped, is 2-lipped, with throat expanded, the lower lip being larger and fringed. The stamens, usually 2, are much exserted. The flowers exhale a balsamic odor, somewhat suggestive of the lemon, and the whole plant when bruised also gives this odor, which is rather disagreeable, especially in the root.

History.—Collinsonia is found in damp, shady situations, and in rich, moist woods, from Canada to Florida, and flowering from July to September. The whole plant has a peculiar, lemon-like, balsamic odor, rather disagreeable in the root, and a spicy, pungent taste. The fresh root, which is the part chiefly employed in Eclectic medicine, is exceedingly hard, requiring to be crushed in an iron mortar, in order to prepare it for pharmaceutical manipulation. It has a sharp, spicy taste. Water and alcohol extract its virtues, but boiling destroys its medicinal properties, as its active principle is evanescent. It is most familiar under the name *Stone-root*, because of the hardness of its root, and not, as stated by Johnson (*Med. Bot.*), on account of its having been formerly used in calculous affections. This plant was named in honor of Peter Collinson, an English merchant, botanist, and antiquarian, who introduced many American trees, shrubs, and plants into English gardens.

Chemical Composition.—Collinsonia has been analyzed by Mr. Lochman (*Amer. Jour. Pharm.*, 1885), and was found to contain resin, starch, tannin, wax in all parts of the plant, mucilage in the root, and volatile oil in the leaves. The therapeutic constituent or constituents of collinsonia have never been recorded if determined. The old Eclectic concentration (or resinoid), has long since become obsolete in the practice of modern Eclectics. It is a mixture of uncertain composition.

Action, Medical Uses, and Dosage.—Collinsonia is said to be alterative, tonic, stimulant, and diuretic. It acts principally on the venous system and mucous tissues, and undoubtedly has a marked action on the vagus, relieving irritation in parts to which that nerve is distributed. Minute doses of the green plant will promptly provoke emesis. The warm infusion will induce perspiration. It has long been a popular domestic remedy for various disorders. The bruised leaves were applied as a poultice in *burns, bruises, wounds, ulcers, sores, sprains, contusions*, and for internal abdominal ailments. The root was used in *female complaints, piles, urinary diseases, and gastro-intestinal affections*.

The remedy has been used with varying degrees of success by the profession in female disorders, as *amenorrhœa, dysmenorrhœa, menorrhagia, vicarious menstruation, prolapsus uteri, leucorrhœa, threatened abortion, and pruritis vulvæ*, dependent on varicosis.

Stone-root, being diuretic and tonic, was formerly much used in genito-urinary troubles. It was highly thought of in *calculous diathesis*. While very much overrated, it is probable that it was not without beneficial results in toning the renal organs and allaying irritation consequent upon the presence of *gravel*. It is certainly a good remedy in *vesical catarrh*. Good results have come from its employment in *spermatorrhœa* and *varicocele*, when accompanied by *piles*. *Catarrhal conditions*, whether of renal, vesical, or genito-urinary organs, or of the respiratory mucous surfaces, are speedily benefited by it. Even the *cough of phthisis* is rendered much less harassing by its administration.

One of the first uses of collinsonia by Eclectics was in the treatment of that form of *laryngitis* known as "*minister's sore throat*." For this condition it is the best agent we possess. It is equally valuable in other forms of *chronic laryngitis, pharyngitis*, and in some cases of *chronic bronchitis, and tracheitis*. It is an excellent remedy for *aphonia*, resulting from vascular hyperemia, or from congestion. In *throat troubles*: R Specific collinsonia, fl̄jii to fl̄j̄; simple syrup, q. s., fl̄jiv. Mix. Sig. Teaspoonful every 3 or 4 hours.

In *diseases of the gastro-intestinal tract*, it is beneficial in relieving irritation, improving the appetite, promoting the flow of gastric juice, and in exerting a decided tonic effect upon the organs involved. It is more clearly indicated when *piles* are present as a complication. It is a good remedy in *indigestion, irritative dyspepsia, chronic gastritis, chronic gastric catarrh, diarrhœa, dysentery, colic, and spasmodic conditions of the stomach and intestines*. By its tonic action upon the bowels, it is a valuable remedy for *constipation*. Perhaps one of the most direct indications for

collinsonia, is a hemorrhoidal and constipated state due to vascular engorgement of the pelvic viscera. The most marked symptoms calling for it will be a sense of constriction, heat, and weight in the rectum, with dry, scybalous feces. Under these conditions the remedy gives marked relief, especially in pregnant women. In rectal ailments give the small dose: R Specific collinsonia, gtt. x to xv; aqua, fl̄iv. Mix. Sig. Teaspoonful every 3 or 4 hours. It is useful also in *hemorrhoids* where there is rectal irritation, with the feces partly scybalous and partly semi-fluid, no constipation being present. Prof. Scudder has found it to effect cures in doses of 1 or 2 drops of specific collinsonia in water, repeated 3 or 4 times a day. *Subacute proctitis*, the tenesmus accompanying *dysentery*, and *dysenteric cholera infantum*, rectal pain and inflammation following surgical operations in that region, irritation attending *anal fistulae*, *rectal ulcers* and *pockets* are all relieved by collinsonia, the latter conditions, however, being only palliated by it. It relieves *neurotic pains* in the rectal region, though no appreciable lesion be observed, and certain forms of *hypogastric pain* are relieved by it when not due to bladder trouble. All of these pains are more amenable to it when associated with *rectal capillary congestion*. Prof. J. M. Scudder valued this agent very highly as a stimulant and tonic in cases of *atonic dyspepsia*, and in chronic disease with feeble digestion, increasing secretion from the kidneys and skin, and in a marked manner relieving irritation of the nervous system and increasing innervation. In chronic diseases of the respiratory apparatus it relieves *pulmonary irritation* and acts as a stimulating expectorant. In *irritation of the pneumogastric nerve*, *heart disease*, and that peculiarly distressing *asthma* simulating, and sometimes attending *phthisis*, he has observed more particularly its superior influence in quieting irritation, giving increased strength and regularity to the heart's action, and increasing the strength of the patient. Collinsonia acts upon the tissues and valves of the heart, relieving irritation, increasing its power to act, and regulating its contractions. It is a serviceable drug in *hydropericardium*, *rheumatic heart troubles*, and functional disturbances due to irritation of the stomach. *Mitral regurgitation* and the distressing *cough of heart disease*, are greatly benefited by its administration. R Specific collinsonia, gtt. iij every hour. Lack of tonicity of the blood vessels is overcome by collinsonia. In short, passive vascular engorgement with dilated capillaries, torpid portal circulation, and lack of muscular tonicity, call for stone-root. The keynote is a *sense of weight and constriction* in the part affected.

Foltz uses collinsonia in *ear diseases* with increased secretions non-purulent in character, failing to get good results after suppuration ensues; he also employs it in the early stage of middle ear disorders when *follicular pharyngitis* and *hyperthrophied Luschka's glands* are complications.

Other species of Collinsonia probably possess similar virtues. Dose of the infusion, from $\frac{1}{4}$ to 2 fluid ounces. Webster prefers a strong tincture of the green plant to that of the root, in doses of a fraction of a drop to 5 drops in acute cases, 4 or 5 times a day in chronic troubles; specific collinsonia (root), $\frac{1}{16}$ to 15 drops, the smaller dose being preferable in hemorrhoids; tincture, 10 to 30 drops 4 times a day.

Collinsonin.—This concentration is a light-brown powder resembling snuff in appearance, and has a slightly bitter, sharp taste. It is but little used.

Specific Indications and Uses.—Prof. Scudder points out as indications for this drug, "a sense of constriction, with irritation in throat, larynx, or anus; a sense of constriction with tickling in throat, with cough arising from use of the voice; a sensation as if a foreign body were lodged in the rectum, with contraction of sphincter, and contracted and painful perineum." Sticking pain in the larynx, heart, or bladder; contracted abdomen; vesical tenesmus; minister's sore throat.

COLLODIUM (U. S. P.)—COLLODION.

Preparation.—"Pyroxylin, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; ether, seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄z, 173 M.]; alcohol, two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄z, 218 M.]. To the pyroxylin, contained in a suitable bottle, add the ether, and let it stand for 15 minutes; then add the alcohol, and shake the bottle until the pyroxylin is dissolved. Cork the bottle well, and set it aside until the liquid has become clear.

Then decant the clear portion from any sediment which may have formed, and transfer it to bottles, which should be well corked. Keep the collodion in cork-stoppered bottles, in a cool place, remote from lights or fire"—(U. S. P.). The U. S. P. process of earlier years prepared both the pyroxylin and the collodion at one operation. The present official process wisely directs the use of ready-prepared pyroxylin (see *Pyroxylinum*).

Description.—Collodion is a colorless, thickish liquid, having a neutral reaction, an ether-like odor and taste, and unless it be kept in well-secured vessels, it thickens and becomes unfit for surgical use, frequently depositing acicular crystals of gun-cotton. When prepared from gun-cotton slightly decomposed, it has an acid reaction, and yields an opaque residue, which is not adhesive, and consequently useless (see *Pyroxylinum*).

Action and Medical Uses.—When placed upon the surface of the body, the part being dry, by evaporation of the ether, a transparent, extremely electric and adhesive film is left, forming an artificial epidermis; in drying, the collodion contracts very strongly, producing local pressure. By thus limiting in a measure the supply of blood, it aids in allaying congestion and inflammation, and materially reduces pain. It has been successfully used in *sore nipples*, *erysipelatous diseases*, *leech-bites*, *bee-stings*, *ulcers*, *burns*, *wounds*, *abrasions*, and several *cutaneous diseases*, over which, when applied, it forms a coating impervious to air, and not affected by water. It forms a good compressor in *orchitis*, *felons*, and *sprains*, and acts well as a splint in *fractures of small bones*, like those of the nose. It is largely used to protect *wounds* and *abrasions* upon the hands of those engaged in dissecting dead bodies, or in performing surgical and gynecological operations. It may be placed upon the part by means of a camel's hair brush, or by layers of thin muslin. In *ulcerations* around the neck of the uterus, collodion has been found beneficial, forming, after the evaporation of the ether, a thin film or coating over the ulcers, thus protecting them from atmospheric influence, and from the vaginal secretions, and facilitating their healing. Collodion is said to have given instant relief in *chilblains*. In many instances, collodion is not commendable, on account of its powerful contraction, which, however, may be obviated by adding to a solution of 1 drachm of gun-cotton in 2½ ounces of ether, 1 drachm of Venice turpentine. M. Sourisseau renders collodion more pliable by adding $\frac{1}{2}$ part of elemi to it. This same property is imparted to it, as stated by M. Startin, by adding $\frac{1}{2}$ or $\frac{1}{4}$ of an ethereal solution of animal fat. Collodion may likewise be prepared pliable and without any tendency to crack or break, by the following formula: Take of collodion, 30 grammes; castor-oil and soft turpentine, of each 50 centigrammes. This is similar in composition to the official *Collodium Flexile*, which was designed for use where great compression is not desirable.

Related Bodies.—**PHOTOXYLON.** A nitro-cellulose, prepared from wood pulp by process of nitration, similar to that for preparing collodion. It is completely dissolved by a mixture of equal amounts of strong ether and alcohol. Upon evaporation a 3 per cent solution leaves a tough collodion-like film (Beringer, *Amer. Jour. Pharm.*, 1888, p. 225). This agent is preferred by some to collodion, as being more impermeable to fluids, adheres better, and exerts a more equal compression of the parts to which it is applied. It is applicable to small *genital* and *facial wounds*, etc.

KAURI GUM.—An exudation from the *Dammara australis*, of New Zealand. When freshly exuded it has little value, but after lying in the soil for a time it is dug and then becomes useful. It is an amber-like body, varying in color from cream to amber. When distilled it yields an oil which is chiefly terpene. A solution of this gum in an equal quantity of alcohol (90 per cent) forms *Baume Calédonien*, a substitute for collodion and for soluble glass. This solution has been lauded in the treatment of *wounds*, *ulcers*, and in *eczematous* and similar *skin diseases*. It leaves an insoluble varnish upon the parts to which it is applied, the film not being easily removed even by friction.

COLLODIUM CANTHARIDATUM (U. S. P.)—CANTHARIDAL COLLODION.

SYNONYMS: *Blistering collodion*, *Collodium vesicans*, *Collodium cantharidale*.

Preparation.—"Cantharides, in No. 60 powder, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; flexible collodion, eighty-five grammes (85 Gm.) [2 ozs. av., 437 grs.]; chloroform, a sufficient quantity; to make one hundred grammes (100

Gm.) [3 ozs. av., 231 grs.]. Pack the cantharides firmly in a cylindrical percolator, and gradually pour chloroform upon it, until the powder is exhausted. Recover the chloroform by distillation from a water-bath, and evaporate the residue, in a capsule, on a water-bath, until it weighs fifteen grammes (15 Gm.) [231 grs.]. Dissolve this in the flexible collodion, and set it aside to become clear by settling. Finally pour off the clear portion from any sediment which may have formed, and transfer it to bottles, which should be securely corked. Keep the cantharidal collodion in cork-stoppered bottles, in a cool place, remote from lights or fire"—(U. S. P.).

Action and Medical Uses.—Cantharidal collodion is used as a vesicant. As an epispastic it is preferred to cantharidal cerate, which it equals in power, being better adapted to uneven parts, and retaining itself better in position. The parts having been well cleansed and dried the blistering agent may be applied by means of a brush, and if, after evaporation of the ether, the parts are not thoroughly covered, it may be reapplied. If covered with oiled silk quicker results may be obtained.

COLLODIUM FLEXILE (U. S. P.)—FLEXIBLE COLLODION.

Preparation.—Collodion, nine hundred and twenty grammes (920 Gm.) [2 lbs. av., 198 grs.]; Canada turpentine, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; castor oil, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Weigh the ingredients, successively, into a tared bottle, and mix them thoroughly. Keep the product in cork-stoppered bottles, in a cool place, remote from lights or fire.

Description.—Flexible collodion closely resembles collodion in appearance. When evaporated it forms a film which is barely contractile and is elastic.

Action and Medical Uses.—Flexible collodion is intended for use chiefly as a protective, where the strongly contractile properties of collodion are not desirable. Like the other collodions it may be applied with a camel's hair brush. Croton oil, cantharides, iodine, salicylic acid, chromic acid, corrosive sublimate, zinc, iron, and copper salts, tannin, etc., are sometimes incorporated with flexible collodion. On account of the intimate contact produced in this way, great care should be exercised in the use of these agents.

Medicated Flexible Collodions.—COLLODIUM IODATUM. (N. F.) *Iodized collodion.* *Formulary number, 24:* "Iodine, reduced to powder, 5 grammes (5 Gm.) [77 grs.]; flexible collodion (U. S. P.), ninety-five grammes (95 Gm.) [3 ozs. av., 154 grs.]. Introduce the iodine into a bottle, add the flexible collodion and agitate until the iodine is dissolved" (Nat. Form.).

COLLODIUM IODOFORMATUM. (N. F.) *Iodoform collodion.* *Formulary number, 25:* "Iodoform, five grammes (5 Gm.) [77 grs.]; flexible collodion (U. S. P.), ninety-five grammes (95 Gm.) [3 ozs. av., 154 grs.]. Dissolve the iodoform in the flexible collodion by agitation" (Nat. Form.).

COLLODIUM TIGLII. (N. F.) *Croton oil collodion.* *Formulary number, 26:* "Croton oil, ten grammes (10 Gm.) [154 grs.]; flexible collodion (U. S. P.), ninety grammes (90 Gm.) [3 ozs. av., 76 grs.]. Mix them" (Nat. Form.).

COLLODIUM SALICYLATUM COMPOSITUM. (N. F.) *Compound salicylated collodion.* *Corn collodion.* *Formulary number, 27:* "Salicylic acid, eleven grammes (11 Gm.) [170 grs.]; extract of Indian hemp, two grammes (2 Gm.) [31 grs.]; alcohol, ten grammes (10 Gm.) [154 grs.]; flexible collodion (U. S. P.), a sufficient quantity; to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Dissolve the extract of Indian hemp in the alcohol, and the salicylic acid in about fifty grammes (50 Gm.) [1 oz. av., 334 grs.] of flexible collodion contained in a tared bottle. Then add the former solution to the latter, and finally add enough flexible collodion to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]" (Nat. Form.). This preparation is largely used as an application to corns.

COLLODIUM STYPTICUM (U. S. P.)—STYPTIC COLLODION.

SYNONYMS: *Styptic colloid, Xylostyptic ether, Collodium hæmostaticum.*

Preparation.—"Tannic acid, twenty grammes (20 Gm.) [309 grs.]; alcohol, five cubic centimeters (5 Cc.) [81 M]; ether, twenty-five cubic centimeters (25 Cc.) [406 M]; collodion, a sufficient quantity, to make one hundred cubic centimeters (100 Cc.) [3 fl. 3, 183 M]. Introduce the tannic acid, alcohol, and ether into a graduated bottle, agitate until the tannic acid is thoroughly incorporated and

partially dissolved, then add enough collodion to make up the volume to one hundred cubic centimeters (100 Cc.) [3 fl $\bar{3}$, 183 M], and shake occasionally until the acid is completely dissolved. Keep the product in cork-stoppered bottles, in a cool place, remote from lights or fire"—(U. S. P.).

The hemostatic effect of collodion is increased by the following *Collodium tannatum* (Pavesi's styptic collodion): Take of collodion 100 parts, carbolic acid 10 parts, tannin 5 parts, benzoic acid 3 parts; mix.

Action and Medical Uses.—This agent, as its name implies, is intended as a styptic to small bleeding surfaces. It may be applied simple or combined with medicinal agents, such as morphine, carbolic acid, etc., to abrasions, ulcerations, and wounds, especially of the scalp. The parts must be thoroughly cleansed, and the collodion applied by means of a small brush, or with cotton wool.

COLOCYNTHIS (U. S. P.)—COLOCYNTH.

"The fruit of *Citrullus Colocynthis*, Schrader, deprived of its rind"—(U. S. P.). (*Cucumis Colocynthis*, Linné; *Colocynthis officinarum*, Schrader).

Nat. Ord.—Cucurbitaceæ.

COMMON NAMES: Bitter apple, Bitter cucumber, Colocynth pulp.

ILLUSTRATIONS: Köhler's *Medizinal-Pflanzen*, Vol. I, Plate 118; Bentley and Trimen, *Med. Plants*, 114.

Botanical Source.—Colocynth is an annual plant, with a whitish root, and prostrate, angular, hispid stems. The leaves are alternate, cordate, ovate, many-lobed, and white, with hairs beneath; the lobes obtuse; the petioles as long as the lamina. The tendrils are short. The flowers axillary, yellow, solitary, and stalked; the females, with tube of the calyx globose, somewhat hispid, and the limb campanulate, with narrow segments. The petals are small. The fruit is globose, smooth, the size of an orange, and yellow when ripe, with a thin, solid rind, and very bitter flesh.

History.—The bitter apple, or cucumber, is a native of Northern Africa (overrunning the sandy spots of Nubia and Upper Egypt after the rainy period), the Cape of Good Hope, Western Asia, Japan, etc., and is cultivated in Italy and Spain.

The fruit assumes a yellow or orange color externally during the autumn, at which time it is collected, and dried quickly, either in a stove or in the sun, after which it is peeled. The colocynth with which the United States is supplied, is chiefly derived from the Mediterranean ports. That which is deprived of its rind, and is very white, light, and spongy, is considered the best article; and the grayish or brownish drug, owing to careless curing, is of the poorest quality. The fruit, as usually met in commerce, is about the size of a small orange, or more generally in broken apples or fragments of the drug devoid of seeds. Occasionally the drug is found with the brown, dried rind intact. A Persian colocynth occurs in the London markets, having a shrivelled appearance, with the seeds tightly imbedded in the pulp, owing to the fact that it has been peeled while still fresh, but the drug of commerce is usually divested of its rind after having been dried. The yellowish-brown seeds ($\frac{1}{4}$ inch long by $\frac{1}{8}$ inch broad) are ovate, flat, and composed of a thick, hard testa, enclosing 2 oily cotyledons, and arranged on the 3 placentæ so as to give the 1-celled fruit a 6-celled appearance. They have been used for food by the poorest Saharan tribes, after being deprived of all the pulp and heated by boiling, roasting, or baking (Flückiger). A paste of the root and fruit is used locally on pimples and boils, and the root (paste), is spread upon enlarged bellies in children, and for rheumatic complaints the root, combined with an equal quantity of long pepper, is administered in pill form in (the Concan) India (Dymock).

Description.—"From 5 to 10 Cm. (2 to 4 inches) in diameter; globular; white or yellowish-white; light, spongy; readily breaking into 3 wedge-shaped pieces, each containing, near the rounded surface, many flat, ovate, brown seeds; inodorous; taste intensely bitter. The pulp only should be used, the seeds being separated and rejected"—(U. S. P.).

FIG. 81.

Fruit of *Citrullus Colocynthis*.

Chemical Composition.—Meissner, in 1818, made a chemical analysis of colocynth. He obtained the bitter principle in an impure form, and called it *colocynthin*. The fruit was further investigated, and various modes of isolating colocynthin were proposed by Vauquelin (1818), Braconnot (1819), Herberger (1830), Labourdais (1848), Bastick (1850), Hübschmann (1858), and Walz (1858), and again, more recently by G. Henke (*Archiv. der Pharm.*, 1883, p. 200). According to Walz, *colocynthin* is a glucosid, the action of diluted acids resolving it into *colocynthein*, a resinous body, and sugar. Walz also describes a crystalline substance, *colocynthitin*, insoluble in water and cold absolute alcohol, but soluble in ether and boiling alcohol. Henke could not obtain colocynthin in crystals, which was the form claimed for it by Walz; contrary to Walz, he also found it insoluble in benzene. Henke's *colocynthin* is insoluble in chloroform, ether, carbon disulphide, and petroleum ether, but is soluble in water (rendering the solution very bitter), alcohol, ammonia water, and an aqueous solution of chromic acid. Tannic acid precipitates it completely from aqueous solution. From 5 kilograms of colocynth deprived of seeds, Henke obtained only 30 grams of colocynthin, and recommends the use of the drug in fresh condition. E. Johansson, in 1885, found *colocynthein* to be less soluble than colocynthin in water, and in acid solution soluble in benzene, which affords a means of separating it from colocynthin. Colocynthin he also found soluble in acetic ether.

Colocynth contains about 4 per cent of fatty oil which is used in India as a remedy (*Jahresbericht der Pharm.*, 1892, p. 28). In addition to the foregoing, Mr. George Wagner (*Proc. A. P. A.*, p. 179), examined colocynth in 1893, and (*Amer. Jour. Pharm.*, p. 272), Prof. L. E. Sayre investigated American colocynth in 1894.

Action, Medical Uses, and Dosage.—Colocynth is irritant and cathartic. It acts very powerfully, producing copious watery evacuations. Even in moderate doses, it has excited inflammation of the mucous membrane of the intestines, vomiting, severe tormina, and bloody stools. Except in minute doses, it is never used alone, because its violence is greatly mitigated, while its efficacy and certainty are not impaired, by uniting it with other cathartics, as aloes, scammony, etc. The addition of extract of hyoscyamus will likewise deprive it of its harsh and griping effects. Its principal employment in material doses is in *passive dropsy*, in *cerebral derangements*, and in pills with other cathartics for the purpose of overcoming torpid conditions of the biliary and digestive systems. However, it is scarcely ever used for these purposes in our school to-day. Its irritant effect upon the rectum may influence the uterus by sympathy of contiguity, and thus provoke menstruation, and on the same principle, dissolved in whiskey, it has cured *gonorrhoea*. It has been used in moderate doses, in all diseases where catharsis is indicated. The powder applied to an ulcer, or raw surface, affects the lower bowels in the same manner as when taken internally, and the tincture applied to the abdomen has purged, and more actively when the surface has been denuded of its epidermis. It is said that Hippocrates used the colocynth apple as a pessary for the purpose of exciting menstruation. Debility and even slight gastro-intestinal inflammation contraindicate the use of colocynth. Later years have developed the true sphere of colocynth as a remedy, and that use is not as a cathartic. It is essentially a remedy for *visceral pain*, and the dose should be very small. Not more than 5 or 10 drops of the specific colocynth should be added to 4 ounces of water, of which the dose is a teaspoonful. Even better are the same number of drops of the 1 x dilution of the specific medicine. The pain calling for colocynth is cutting, darting, cramping, or tearing. It is of great value in *stomach and intestinal disorders* with sharp "belly-ache," and meets these disorders even when rheumatoid, and is particularly valuable in *neuralgic pains of the viscera*. The patient is cold, weak, and feels faint; the pain of a sharp character causing him to flex his body upon his thighs. The back, joints, and bones feel stiff and sore, as if bruised, and the abdominal pain is made worse by motion. It is an important remedy in *dyspepsia*, with bitter taste, bilious yellow and bitter eructations, and bloating after eating, accompanied with sharp griping or cutting, colic-like pain in the umbilical region. The minute dose here acts best: R Specific colocynth, 1 x dil., gtt. j to x; aqua, fl̄iv. Mix. Teaspoonful every 3 or 4 hours. The same characteristics indicate it in *flatulent, worm and bilious colics*. The accumulation of gases may be large, producing by distension disturbances of the

breathing organs and heart, with much anxiety, and belching, or expulsions of flatus may be symptoms, and nausea and vomiting are not uncommon. *Cholera infantum* sometimes presents many of these symptoms, and colocynth will give prompt relief. *Chronic diarrhæa*, with slimy stools and distended abdomen and the characteristic pain, or *diarrhæa* due to overeating or improper food are relieved by it. In *dysentery*, with cutting tormina and tenesmus and ineffectual efforts at stool, it is an admirable remedy. It should not be overlooked in *liver disorders* with tympanites, constipated bowels, and sharp, darting pains in the liver region; and in the *chronic constipation* of women and children with the symptoms above mentioned, and, in addition, dry, hard scybalous feces, its tonic action is marked and gastric and intestinal digestion improved, with a consequent improvement of the constipated state. In fact, in chronic disorders of any kind in which colocynth aids, there is an evident intestinal and hepatic inactivity. Certain forms of *head-ache*, with the colocynth pain, whether neuralgic or reflex from stomach troubles, are remedied with colocynth. It exerts a direct influence upon the nervous system, relieving *neuralgia* of the parts supplied by the solar plexus, *neuralgic colic*, *ovarian neuralgia*, *orchialgia*, *neuralgia of the fifth nerve*, and *sciatica*, all presenting the characteristic sharp, cutting pain. The same is true in *rheumatic complaints* and *lumbago*. Colocynth is decided in its action upon the female organs of reproduction. When colicky pains precede or accompany *amenorrhæa*, and pressure gives relief, colocynth is the remedy; other painful states of these organs are relieved when the cases are properly selected. A characteristic of colocynth is that, if it is to help at all, it helps quickly, but the smaller doses should be tried before a failure is declared. The oil of colocynth has been recommended as an external remedy for *neuralgia*. The dose for the old cathartic use of colocynth is from 4 to 10 grains, either in powder or aqueous extract; of the alcoholic extract, from 1 to 4 grains. When to be given alone, it should be triturated with some inert or insoluble powders, as gum or farinaceous matter, in order to diminish its severity of action. For the newer and specific uses of colocynth: R Specific colocynth (or 1 x dil.), gtt. j to x, aqua, f3iv. Mix. Dose, a teaspoonful every 1 to 4 hours.

Specific Indications and Uses.—Pain of a cutting, twisting, boring, griping, contractive character, and if of the gastro-intestinal tract, accompanied with a desire to go to stool; colicky pains in the umbilical, iliac, and hypogastric regions; dysentery, with tormina in right iliac region or diffused over the abdomen; diarrhæa, with shining, mucoid passages, and tenesmic, colicky pain; constipation, with dry scybala and sharp, griping pain in the lower bowel; flatulent eructations and discharges; tensive rheumatic pain, with contractions; visceral neuralgia of cutting character.

Related Species.—*Cucumis trigonus*, Roxburgh (*Cucumis Pseudo-colocynthis*, Royle); *Kari*.—North India, especially the presidency of Bombay. The fruit is exceedingly bitter, and resembles a small egg streaked with yellow and green. It is carried into market during the Hindu New Year feast. At this time the Bombay Hindus are accustomed to crush a gourd with the foot, touch the forehead and tongue with it, thus, of their own accord, *tasting bitter*, hoping thereby to be protected and preserved from calamities throughout that year. It is employed medicinally, but not for food. A variety (var. *pubescens*), not so bitter, after soaking in salt water, is eaten like the cucumber, and the seeds are employed in *herpes* (see Dymock, *Mat. Medica Western India*).

Cucumis Hardwickii, Royle; *Hill colocynth of India*.—Purgative

Cucumis prophetarum, Linnæus.—Arabia. Purgative.

Luffa operculata, Cogn.—Brazil. The drastic fruit of this plant has been employed in affections for which colocynth is used. The boiled fruit pulp is strained, beaten into froth, and, when cold, given in tablespoonful doses for *dropical complaints* until either purging or vomiting is induced. It is quite a popular domestic remedy in its native habitat (*Amer. Jour. Pharm.*, Vol. 56). For *Luffa echinata*, Roxburgh and its constituents, see *Amer. Jour. Pharm.*, 1888, p. 486.

Luffa acutangula var. *amara*, Roxburgh.—The *Karvi-turai* of the Hindus who employ the fruit and vine medicinally. It possesses cathartic and emetic properties for which purposes the infusion of the ripe seeds is generally preferred. The juice of the fruit is employed locally for *headache* and *bites*. The bitter leaves are employed in Bombay for *sores* upon cattle (Dymock, *Mat. Med. Western India*).

Cucumis myriocarpus.—The *Cacur* of southern Africa. Has active emeto-cathartic properties, similar to those of colocynth, and, after heating, is used by the natives for its emetic action. It contains a neutral, resinous substance (*myriocarpin*) which is also emeto-cathartic.

CAYAPONINE.—The alkaloid extracted by Gubler from *Cayaponia globulosa* (*Nat. Ord.*—Cucurbitaceæ), of Brazil. In doses of $\frac{1}{16}$ grain it is said to purge without pain.

COMPTONIA.—SWEET FERN.

The plant and especially the leaves and tops of *Comptonia asplenifolia*, Aiton (*Myrica asplenifolia*, Linné; *Myrica Comptonia*, De Candolle).

Nat. Ord.—Myricaceæ.

COMMON NAMES: *Sweet fern*, *Meadow fern*, *Ferngale*.

Botanical Source.—Sweet fern is a low, indigenous shrub, with a long, horizontal root, and growing from 2 to 4 feet high, the main stem being covered with a rusty, brown bark, which becomes reddish in the branches, and white-downy in the young shoots. The leaves are numerous, on short peduncles, from 3 to 4 inches in length, $\frac{1}{2}$ inch broad, alternate, linear-lanceolate, sinuate-pinnatifid, resembling the leaves of the spleenwort fern, brown, rather downy on the under side, shining on the upper. The stipules in pairs and acuminate. The flowers are green, monœcious, amentaceous, appearing before the leaves; barren ones in long, erect, cylindrical, loosely imbricated catkins, terminal and lateral, with deciduous, 1-flowered bracts; the fertile ones in ovate, densely imbricated catkins, situated below the barren ones, with 1-flowered bracts. Stamens 6, adhering in pairs. Sepals 6, larger than the bracts; styles 2, capillary. The fruit is a small, ovate, brown, 1-celled nut (L.—W.).

History.—This plant is found growing in thin, sandy soils, or dry, rocky woods, from Maine to Kentucky, flowering in May. The whole plant possesses a spicy, aromatic odor, especially when bruised, and an aromatic, astringent, faintly bitterish taste. The whole herb is used, and imparts its virtues to water or alcohol. The leaves have been used in the rural districts of New York state as a substitute for tea.

Chemical Composition.—H. K. Bowman (*Amer. Jour. Pharm.*, 1869, p. 194), found the leaves to contain 8.2 per cent of tannin, corroborated by Charles G. Manger, who, in 1894, made a complete analysis of both the rhizome and the leaves of *Myrica asplenifolia*. He found the amount of tannin to vary with the season; dried January leaves containing 7.06 per cent, July leaves 10.28 per cent. Tannin in the dried rhizome reached a maximum of 6 per cent in a sample collected in August. Starch was not found in the leaves, but the rhizome contained 8.24 per cent. By distilling the leaves with water, Mr. Manger isolated a small amount of an aromatic volatile oil, which was liable to resinify upon exposure to the air. R. T. Chiles, in 1873, found gallic acid in the leaves, the usual plant constituents, and a body resembling saponin. Peacock subsequently could detect traces only of gallic acid in a January specimen of the rhizome, and none at all in a specimen collected in June (*Amer. Jour. Pharm.*, 1892).

Action, Medical Uses, and Dosage.—Tonic, astringent, and alterative. Used in *diarrhœa*, *dysentery*, *hemoptysis*, *leucorrhœa*, *rheumatism*, *debility* succeeding *fevers*, and in *rachitis*. A decoction of it is very useful in the *summer complaints of children*, when given as an auxiliary. A pillow of the leaves is beneficial to rachitic children, and they may be used as a fomentation in *contusions* and *rheumatism*. Dose of the decoction, from 1 to 4 fluid ounces, 3 or 4 times a day.

CONDURANGO.—CONDURANGO.

The bark of *Gonolobus Condurango*, Triana (*Marsdenia Condurango*, Reichenbach).

Nat. Ord.—Asclepiadaceæ.

COMMON NAMES: *Eagle vine*, *Mata-peroo*.

Botanical Source.—This plant is a twining vine, having opposite cordate leaves, which are cuspidate and sinuately narrowing on the margins, hairy above and silky and tomentose underneath. The flowers are borne in loose cymes. The peduncles and petioles are covered with a pale, grayish pubescence, and the stem, which reaches a thickness of from 1 to 5 inches and a great height, has a greenish-gray bark, which, when cut or bruised, exudes a viscid, milky juice.

History.—Condurango was introduced, in 1871, in rather an official manner, having been received by the State Department at Washington, from the Minister of Ecuador. The drug was accompanied by certificates from two physicians of

the province of Loja, attributing to the bark great power to cure cancer, syphilis, etc. The statements were supported by a letter from our Minister at Ecuador. An analysis of the plant (see below) threw but little light upon the subject, as substances common to most plants only were found. Shortly after it came into notice, a note from Mr. Dan. C. Robbins, of New York, to the editor of the *Amer. Jour. Pharm.*, stated that Mr. Wiehl, United States Consul at Guayaquil, had favored him with specimens of the flowers, leaves, and fruit of the true condurango vine. It was stated that the name condurango meant "Eagle vine," or "Condor-vine," and that there were some 6 varieties, 3 of which were used in medicine, and were known in Spanish by names signifying dog-killer, big fruit, and little fruit. The "dog-killer," which is true condurango, is a tropical climbing vine, seeking the highest trees of the cinchona region of South America. Doubtless, the market is supplied with barks of several species of climbing plants.

Description and Chemical Composition.—The bark only is recommended for use. It is in thin pieces, of a whitish or yellowish color, in appearance reminding one of the bark of ptelea root. The taste is slightly bitter and aromatic. Thomas Antisell (*Amer. Jour. Pharm.*, 1871) found in 100 parts of condurango bark: Moisture (8 per cent), ash (12 per cent), fatty matter (7 per cent), yellow resin, soluble in alcohol (2.7 per cent), gum and glucose from starch (0.5 per cent), tannin and coloring matters (12.6 per cent), cellulose, lignin, etc. (63.5 per cent). In 1872, Vulpus observed a precipitate that formed upon warming of a clear, aqueous infusion of the bark, and which suggested the presence of a substance related to Tanret's *vincetoxin*, from the root of *Asclepias vincetoxicum*. In 1885, Vulpus pronounced the glucosidal nature of this substance, which he named *condurangin*, admitting, however, that it might not be a simple body. A 2 per cent solution in water has the property of gelatinizing upon warming, and becoming clear again when cold. Condurangin, while a glucosid, also reacts with alkaloidal reagents. Vulpus resolved it into two substances, one soluble in water, and insoluble in ether, and another with these solubilities reversed (*Archiv. der Pharm.*, 1885, p. 299).

Kobert and Jukna (1888) investigated condurangin both chemically and physiologically, and Carrara (1892) examined Vulpus' decomposition products, establishing formulæ and melting points for both. He also announced the presence of a new glucosid of the formula $C_{28}H_{44}O_8$, having a melting point of $112^{\circ}C.$ ($233.6^{\circ}F.$), insoluble in ether, sparingly soluble in cold alcohol, and very slightly soluble in water. It is not precipitated by Mayer's reagent, nor with iodine in solution of iodide of potassium. The same observer found *conduransterin* ($C_{28}H_{44}O_8$), melting point $52^{\circ}C.$ ($125.6^{\circ}F.$), a body related to cholesterin. It is contained in the ether solution of the precipitate formed in the cooled alcoholic extract. *Cinnamic acid* was also isolated from the mother-liquors. Schroff and Schmiedeberg, (*Med. Chir. Rundschau*, 1871-2) believed that an alkaloid, resembling strychnine in its action, must be present in the bark, and Flückiger, in 1882, obtained minute quantities of an alkaloid.

Action, Medical Uses, and Dosage.—This agent, at one time so highly lauded as a positive remedy for *cancer* and *syphilis*, is rarely employed at the present time, and should it possess any valuable therapeutic virtues, they are not likely to be ascertained for some time to come, as the exaggerated statements and misrepresentations attending its introduction have led the profession to regard it with suspicion and incredulity. It is probable, however, that it has a tonic effect in *gastric debility*, and especially relieves pain in the stomach. Condurangin, according to Kobert, acts upon the central nervous apparatus, producing in animals impairment of appetite, vomiting, ptialism, muscular weakness, convulsions and paralysis. Of condurango a decoction (bark 3ss to aqua Oj boiled down to Oss.) may be given in tablespoonful doses 3 times a day; fluid extract, 5 to 30 drops.

CONFECTIONES.—CONFECTIONS.

The Pharmacopœias still recognize two members of a class of preparations, but little used at the present, and yet modifications of them were very important medicines in former times under the terms *conserves* and *electuaries*. CONFECTIONS

are semi-solid preparations of medicinal agents preserved by means of sugar, or honey, or both. CONSERVES, as originally understood, were composed of fresh or undried, medicinal vegetables laid down in sugar. Subsequently it became common to prepare them by beating fresh vegetable medicines and sugar into a uniform soft mass, the juices of the vegetables furnishing sufficient moisture. When fresh drugs were not obtainable, dried drugs, either whole or powdered, were used, and sufficient water added to soften the mass. ELECTUARIES were understood to comprise the mixture of powdered drugs with such softening and preserving agents as honey, syrups, or pulps, made into a uniform, pasty mass by thorough trituration in a mortar. If honey and pulpy substances are employed the electuary is not apt to become dry, hard, and crystalline, as is often the case when syrups are used. Such substances as light insoluble salts, soluble salts, extracts, oils, gum-resins, etc., may be made into electuaries. Heavy insoluble powders should not be used, as they are likely to settle, and finally to be found mainly at the bottom of the preparation. Extracts to be used in preparing electuaries, should first be softened with water or other suitable liquids; non-pulverizable gum-resins should first be emulsified, and essential oils should be first rubbed with some inert powder or sugar. Freshly made electuaries should be soft enough to drop easily from a spatula. If so soft that the ingredients separate on standing they must be again brought into a uniform mixture by stirring. It is desirable that they be firm enough to hold up their several ingredients, and still be so soft that mastication is not required. As already stated, the confections displaced both these sweets (conserves and electuaries) of mediæval medicine, and very properly so, and in turn confections have given way to other and better pharmaceutical preparations.

CONFECTIO OPII.—CONFECTIO OF OPIUM.

SYNONYM: *Electuarium theriaca*.

Preparation.—The U. S. P. of 1870 recorded the following formula: "Take of opium in fine powder, 270 grains; aromatic powder, 6 troy ounces; clarified honey, 14 troy ounces. Rub the opium with the aromatic powder, then add the honey, and beat the whole together until thoroughly mixed." This contains 1 grain of opium in about every 36 grains of the confection.

Action, Medical Uses, and Dosage.—This confection was designed to take the place of the ancient mixtures known as *Theriaca* and *Mithridatum*. It is said to be useful in debilitated conditions with *diarrhoea*, *weak digestion*, with flatulence, *gouty conditions*, and other states where a stimulating opiate is thought necessary. The dose ranges from 5 to 20 grains.

CONFECTIO ROSÆ (U. S. P.)—CONFECTIO OF ROSE.

SYNONYM: *Conserve of rose*.

Preparation.—"Red rose, in No. 60 powder, eighty grammes (80 Gm.) [2 ozs. av., 360 grs.]; sugar, in fine powder, six hundred and forty grammes (640 Gm.) [1 lb. av., 6 ozs., 252 grs.]; clarified honey, one hundred and twenty grammes (120 Gm.) [4 ozs. av., 102 grs.]; stronger rose water, one hundred and sixty cubic centimeters (160 Cc.) [5 fl. oz., 197 Ml.]. Rub the red rose with the stronger rose water previously heated to 65° C. (149° F.), then gradually add the sugar and honey, and beat the whole together until a uniform mass results"—(U. S. P.).

CONFECTIO SENNAE (U. S. P.)—CONFECTIO OF SENNA.

SYNONYMS: *Electuary of senna*, *Lentitive electuary*.

Preparation.—"Senna, in No. 60 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; cassia fistula, bruised, one hundred and sixty grammes (160 Gm.) [5 ozs. av., 282 grs.]; tamarind, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; prune, sliced, seventy grammes (70 Gm.) [2 ozs. av., 205 grs.]; fig, bruised, one hundred and twenty grammes (120 Gm.) [4 ozs. av., 102 grs.]; sugar,

in fine powder, five hundred and fifty-five grammes (555 Gm.) [1 lb. av., 3 ozs., 252 grs.]; oil of coriander, five grammes (5 Gm.) [77 grs.]; water, a sufficient quantity to make one thousand grammes, (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Place the cassia fistula, tamarind, prune, and fig in a close vessel with five hundred cubic centimeters (500 Cc.) [16 fl. 3, 435 M.] of water, and digest for 3 hours by means of a water-bath. Separate the coarser portions with the hand, and rub the pulpy mass, first through a coarse hair sieve, and then through a fine one, or through a muslin cloth. Mix the residue with one hundred and fifty cubic centimeters (150 Cc.) [5 fl. 3, 85 M.] of water, and having digested the mixture for a short time, treat it as before, and add the product to the pulpy mass first obtained. Then, by means of a water-bath, dissolve the sugar in the pulpy liquid, and evaporate the whole, in a tared vessel, until it weighs eight hundred and ninety-five grammes (895 Gm.) [1 lb. av., 15 ozs., 250 grs.]. Lastly, add the senna and the oil of coriander, and incorporate them thoroughly with the other ingredients while they are yet warm"—(U. S. P.).

Action, Medical Uses, and Dosage.—When correctly prepared, this confection is a pleasant, mild, and very effectual purgative, useful during pregnancy, and for patients afflicted with costiveness, hemorrhoids, or diseases of the rectum. It forms a vehicle for the administration of some purgative drugs. The dose is from 1 to 3 drachms, or more.

CONFECTIO SENNAE COMPOSITA.—COMPOUND CONFECTION OF SENNA.

SYNONYM: *Compound electuary of senna.*

Preparation.—Take of confection of senna 1 ounce, bitartrate of potassium $\frac{1}{2}$ ounce, pulverized jalap 3 drachms; nitrate of potassium, flowers of sulphur, each, 2 drachms; extract of butternut, a sufficient quantity to form into a mass of pilular consistence. Keep in small glass jars well covered with tin foil.

Action, Medical Uses, and Dosage.—This confection has been used with advantage in constipation and in hemorrhoids of whatever form. A dose of 12 or 16 grains may be taken in pill form, repeating it twice a day, so as to act mildly on the bowels.

CONFECTIO SULPHURIS.—CONFECTION OF SULPHUR.

SYNONYM: *Electuarium sulphuris.*

Preparation.—Rub intimately together, 4 ounces (av.) of sulphur, 1 ounce (av.) of potassium bitartrate, 4 fluid ounces of syrup of orange-peel, and 18 grains of powdered tragacanth.

Action, Medical Uses, and Dosage.—This method of exhibiting the two laxatives, sulphur and cream of tartar, is beneficial in cases of hemorrhoids. The stools produced are semi-solid and copious. The dose is from 1 to 2 drachms.

CONFECTIO TEREBINTHINAE.—CONFECTION OF TURPENTINE.

SYNONYM: *Electuarium terebinthinctum.*

Preparation.—Take 1 ounce of oil of turpentine, 1 ounce of powdered licorice-root, and 2 ounces of clarified honey. Rub first the turpentine and licorice together, and mix in the honey until the whole is uniformly and intimately mixed.

Action, Medical Uses, and Dosage.—This is a convenient form for administering turpentine in cases of flatulence, round worms, rheumatic complaints, tympanites, and passive hemorrhages. The dose ranges from 1 to 2 drachms.

CONIUM (U. S. P.)—CONIUM.

"The full grown fruit of *Conium maculatum*, Linné," "gathered while yet green"—(U. S. P.) (*Cicuta maculata*, Lamarek). The leaves are official in the *British Pharmacopœia*.

Nat. Ord.—Umbelliferae.

COMMON NAMES: *Hemlock, Poison hemlock, Spotted hemlock, Poison parsley.*

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 118.

Botanical Source.—Poison hemlock has a biennial, fusiform, whitish, fleshy root. Its stem is from 3 to 5 feet high, erect, round, hollow, glaucous, polished, and

Conium maculatum.

copiously spotted and dotted with dull purple. The leaves are tripinnate; the lower ones very large, several times pinnate, and bright-green, on long, sheathing foot stalks. The leaflets are ovate, lanceolate, pinnatifid, lower lobes incised. The flowers are numerous, small, white, all fertile, outermost very slightly irregular, and are arranged in erect, terminal, compound, many-rayed, smooth umbels. The general involucre is ovate, cuspidate, with membranous edges, consisting of from 3 to 7 lanceolate, reflected bracts, with whitish edges; the partial involucre of 3 or 4 oval, pointed, spreading bracts, with the inner side wanting. The petals are obcordate, with acute, inflexed points, and 5 in number. The fruit is about a line and a half, or rather less in length, by a line in breadth; roundish-ovate, compressed, of a pale-green color; the primary ridges are elevated, sharp and undulated; the commissures and channels finely wrinkled.

The whole plant exhales a disagreeable, virose odor, more especially when bruised (L.—W.).

History.—Hemlock inhabits Europe and Asia, and has been introduced in many parts of this country. It flowers from May to August. The leaves and seeds are the parts used. The leaves are best when collected during the flowering seasons of the herb; they should be speedily dried by a gentle heat, not over 47.7° C. (118° F.), and placed in closely covered vessels, to preserve them as much as possible from the influence of the atmosphere and light. If properly dried, the leaves should have a fine green color, with a disagreeable odor, less powerful than in the fresh plant, and a peculiar, nauseous, saline, and somewhat acrid taste. The fruit, or seeds, should be gathered shortly previous to ripening. Both the leaves and seed yield their virtues to alcohol or ether. The aqueous extract is uncertain; the alcoholic extract is the best, but even this becomes destitute of coniine in a few years (P.). The fresh leaves and fruit should be employed in the preparation of the active constituent.

Description.—CONIUM (U. S. P.).—The fruit is thus described in the U. S. P.: "About 3 Mm. ($\frac{1}{8}$ inch) long; broadly ovate; laterally compressed; grayish-green; often divided into the 2 mericarps, each with 5 crenate ribs, without oil tubes, and containing a seed which is grooved on the face; odor and taste slight. When triturated with solution of potassium or sodium hydrate, conium gives off a strong, disagreeable, mouse-like odor"—(U. S. P.).

CONIUM LEAVES.—(See *History* and *Botanical Source*).

Chemical Composition.—The active principles of conium are the *alkaloids*, of which 5 have been identified (C. E. Sohn, 1894, *Dictionary of Active Principles of Plants*): *Coniine* ($C_8H_{17}N$), identified with *conicine* and *cicutine*; *conhydrine* ($C_8H_{17}NO$), discovered by Wertheim, in 1856; *pseudo-conhydrine* ($C_8H_{17}NO$), isolated by E. Merck, in 1891; *methyl-coniine* ($C_9H_{19}N$); and *ethyl-piperidine* ($C_9H_{19}N$). The mixed alkaloids may be prepared by distilling a mixture of strong solution of caustic potash and alcoholic extract of the unripe fruit, whereupon they pass over, forming an oily layer in the receiver. According to directions of J. Schorm (1882) the conium fruits, moistened with water, rendered alkaline with sodium carbonate, are distilled with steam under a pressure of 3 atmospheres. The distilled oil is neutralized with hydrochloric acid, evaporated, and treated with alcohol. After removal of the alcohol on the water-bath, an equivalent amount of caustic soda is added, and the alkaloids then shaken out with ether. The ethereal solution is reduced to a low temperature, whereby the bulk of *conhydrine* separates in the form of

long needles. The remaining traces will evaporate with the ether, pure *coniine* remaining (*Amer. Jour. Pharm.*, 1882).

Coniine, when pure, is an oily-like, transparent, colorless liquid, becoming brownish by oxidation, of specific gravity 0.86, with a very penetrating, tobacco-like odor, and a sharp, acrid, benumbing, and offensive taste. At ordinary temperatures it is volatile, disengaging ammonia, depositing a resinous matter, and losing its activity; its vapor excites a flow of tears. It is soluble in 90 parts of water, and forms a hydrate by uniting with about a fourth part of water, which, in cold, saturated solution, becomes turbid by heat owing to the separation of the water of hydration. It is very soluble in alcohol, ether, benzine, chloroform, benzol, the fixed and volatile oils, and also in weak acids, which it neutralizes. It boils at about 171° C. (340° F.), and distills over with water at 100° C. (212° F.). It strongly blues reddened litmus paper and forms soluble salts with acids, which, excepting the hydrochlorate, are difficult to crystallize. Caustic potash added to salts of coniine sets the base free, which is then recognized by its odor; heat produces the same effect on most of its salts. As to the behavior of coniine towards reagents, see *Amer. Disp.*, last edition; also C. E. Sohn (see above).

Coniine possesses the same remarkable action on the spinal cord as hemlock itself. A few drops will suffice to kill a cat, rabbit, or young dog; a strong cat was killed in a minute and a half by 8 drops of it. Its effects are gradual paralysis, slight convulsive tremors, and death from suspension of the breathing, without any change in the appearance of the blood, and without any depression of the heart's action.

Coniine was observed by Giesecke as early as 1827, and obtained in the form of an impure sulphate. Geiger, in 1831, obtained it pure and recognized its alkaloidal nature. It is present in all parts of hemlock, probably in combination with *malic acid* (Husemann and Hilger, 1884). It is optically active, turning the plane of polarized light to the right. Its present formula was established, in 1881, by A. W. Hoffmann, and its synthesis was accomplished, in 1886, by Ladenburg, who first prepared inactive *coniine* (*alpha-propyl piperidine* ($C_8H_{17}[C_2H_5]NH$)), and succeeded in isolating therefrom the active alkaloid by adding a crystal of the tartrate of the dextrogyrate alkaloid to the syrupy solution of the tartrate of the inactive alkaloid.

Conhydrine ($C_8H_{17}NO$), discovered by Wertheim, is an oxyconiine occurring in commercial coniine from which it separates on cooling to near 0° C. (32° F.). Its melting point is 126° C. (258.8° F.).

Pseudo-conhydrine ($C_8H_{17}NO$) was discovered by E. Merck, in 1891, in the high boiling portions of crude coniine. It crystallizes in needles, is easily soluble in alcohol, ether, and chloroform, and fuses at about 98° C. (218.4° F.). Its boiling point is 230° to 232° C. (446° to 449.6° F.).

Methyl-coniine ($C_9H_{19}N$), an oily base, and associated with coniine, was found by Von Planta and Kekulé in hemlock (1854). It is a homologue of coniine, or rather of its isomer, *paraconiine*, prepared by Schiff, in 1871. G. Liljenstroem (*Amer. Jour. Pharm.*, 1894), calls attention to the difficulty of accurately determining the quantity of the alkaloid in extract of conium by means of continuous extraction with ether, owing to the volatility of coniine, even though a reflux condenser is employed. He suggests that a known amount of centinormal acid be placed in the receiver, which readily absorbs coniine, and to titrate back the excess of acid. Wertheim obtained from fresh seeds about 0.20 per cent of pure coniine.

Action, Medical Uses, and Dosage.—Conium is narcotic, possessing, however, properties somewhat similar to those of belladonna. On account of the former difficulty in procuring good preparations of this plant, it has not been so much used nor its virtues so fully investigated, as with some of its congeners. The symptoms produced by its use are thirst, dryness of the throat, dizziness, sickness at stomach, sinking, benumbing feelings, and more or less prostration of the muscular system. If its use be continued, or in large doses, the pupils become dilated, there is a general paralysis, rendering talking and breathing difficult, with coma, or convulsions terminating in death. In about 30 minutes from its administration, its effects will generally appear, and continue from 10 to 40 hours. It is supposed to effect its results by exhausting the nervous energy of the spinal cord

and voluntary muscles. It is used for promoting sleep, and will be found extremely useful in allaying excessive action of the heart in hypertrophy of this organ; a pill of 1 or 2 grains of the extract producing a calm, soothing influence, followed by a diminution or removal of the palpitation or augmented action. Indeed, all affections attended with an excited or excitable condition of the nervous and vascular systems, will be benefited by its use. Dr. J. Harley considered conium as a depressor of the muscular movements, tranquilizing and renovating the whole muscular system—being to the corpora striata, the smaller nervous centers, and the whole of the motor tract, just what opium is to the brain. It depresses the motor function of the third nerve, causing a lazy movement of the eyes, and sometimes strabismus, with imperfect adjustment of the refracting media of the eye. It affects the sedentary and strong more than the delicate and active, so that its action is influenced more by the muscular activity than by the muscular power. It has no pure cerebral effects, but diminishes irritability of the spinal cord without disturbing the sensory functions. It has no direct action on the sympathetic; improves nutrition; and can not be detected in the urine, breath, or feces. He considered it preeminently useful in *laryngismus stridulus*, *convulsive cough*, and in *tetanic muscular conditions*. The dose must be proportioned to the degree of motor activity of the child or adult; by its use we may almost measure the bodily activity of the individual. To a child 21 months old he has given 20 minims of the prepared juice, and gradually increased it to 2½ fluid drachms.

Conium has in times past been lauded in *cancer*, and, while it undoubtedly has influenced growths pronounced cancerous, it is not known to have effected a cure. The pain of cancer, however, is alleviated by it, and it undoubtedly affects *tumors of the mammae*, even when they amount to *scirrhus*. Conium has been used to check lactation, thus showing its specific action upon the mammary glands. *Ovarian torpor*, giving rise to scanty menses, and *sterility* in the female, and in the genital feebleness of the male, accompanied with an unpleasant erethism, or where lack of sexual activity is due to passive testicular venous engorgement, conium is said to be efficient when given in small doses. *Glandular enlargements* sometimes yield to the alterative influence of this drug, and while not generally efficient in *sypilis*, as some of its admirers claim, it is useful in allaying the pains which accompany that affection. In *rheumatism* and *neuralgia*, R Specific conium, gtt. v to x; aqua, flʒiv. Mix. Sig. Dose, a teaspoonful as often as necessary, or give from ½ to 2 grains of the English extract. *Chorea* and *epilepsy*, due to sexual abuse, and *whooping-cough* and *acute mania* are states in which it is asserted useful. It has been variously used in cachectic and depraved states, either as a palliative or for its curative action. Large doses are contraindicated by debility.

In consequence of the action of conium on the spinal marrow, it lessens the venereal appetite. It likewise lessens the secretion of milk. In the *neuralgic pains* attending *carcinomatous affections* it usually gives relief, probably, from its causing relaxation of muscular fibers; sometimes, however, it has exerted no influence whatever, in palliating them. In *scrofula*, *goutre*, and, indeed, in all *tuberculous affections*, it will be found very effectual given in combination with the iodide of iron. It enters into the compound plaster of belladonna, an excellent preparation, which Prof. King used for many years. Coniine, the active principle, is not extensively used in medicine. The hydrochlorate, benzoate, and, best of all, the hydrobromate have been most used, the latter particularly in *whooping-cough* and *sciatica*. Dr. Reid gives the following formula for toothache: Take of coniine, 1 drop; rectified alcohol, essence of cinnamon, each, 4 drops. Mix. This is applied by means of a camel's hair pencil. It relieves the pain instantly, but produces no effect where the nerve is not exposed by caries; a few minutes after its application there will be vertigo, difficulty of swallowing, etc., which usually cease in about 10 or 20 minutes. It should not be too frequently, nor too largely applied. The leaves have likewise been employed externally as a poultice to *painful tumors*, *ulcers*, *neuralgic* and *rheumatic pains*, etc. For painful parts the following is useful: R English extract of conium, ʒij; petrolatum, ʒvj. Mix. Apply. In *intermittent fever*, Dr. King frequently employed the following pill when quinine alone failed: Take of sulphate of quinine, 10 grains; inspissated

juice of conium, 15 grains. Mix and divide into 20 pills, of which 1 pill may be given every 1 or 2 hours, until the effects of the conium have commenced, after which give 1 pill every 4, or 5 hours, according to its influence. The aqueous extract of the plant is worthless; the inspissated juice, or the ethereal extract, are alone valuable only when they are carefully and properly prepared. A strong solution of the inspissated juice, or the juice of the fresh leaves, coated over the parts daily, for 5 or 6 days, will cure the *itch*. Dose of the leaves and inspissated juice, from 1 to 3 grains, 3 or 4 times a day; of the ethereal extract, which is an elegant extract of a rich, dark-green color, from $\frac{1}{4}$ to $\frac{1}{2}$ grain; coniine, $\frac{1}{16}$ to $\frac{1}{8}$ grain; coniine bromohydrate, $\frac{1}{16}$ to $\frac{1}{8}$ grain; coniine hydrochlorate, $\frac{1}{16}$ to $\frac{1}{8}$ grain; coniine benzoate, $\frac{1}{16}$ to $\frac{1}{8}$ grain; specific conium, $\frac{1}{16}$ to 3 drops.

Specific Indications and Uses.—To relieve nervous excitation and give rest; neuralgic or rheumatic pains in the old and feeble, or where there are caco-plastic deposits; pain in stomach; pain of gastric ulcer; nervousness and restlessness.

Related Species.—*Cicuta maculata*, Linné, *Spotted water-hemlock*, *Spotted parsley*, *Spotted cowbane*, *Beaver poison*, *Musquash root*, *American water-hemlock*. North America. This plant differs from the following in having a purple-spotted stem, wider leaflets, and long, tuberous, fleshy roots. A volatile alkaloidal principle, believed to be coniine, was isolated by J. E. Young (*Amer. Jour. Pharm.*, 1855, p. 299). Mr. Glenk, in 1891, made a complete analysis of the fruit. The volatile oil was investigated recently by Mr. Stroup and found to consist mainly of terpenes (see *Amer. Jour. Pharm.*, 1894, p. 236).

Cicuta virosa, Linné (*Cicutaria aquatica*, Lamarck); *Water hemlock*, *Cowbane*.—This plant grows in wet situations from Canada north. Its rhizome is short, somewhat ovate, thick, and hollow, and has attached rootlets arranged in circles. The taste of the plant is aromatic and acrid, and its odor slightly aromatic. The plant, but not the root, as shown by Van Ankum's researches (1868), contains *cicutine*, a volatile alkaloid. *Cicutarin* is a name applied by Boehm and Trojanowski, in 1887, to a soft, amorphous and tenacious yellow substance existing in the rhizome to the extent of 3.5 per cent. *Cicuta* is used as a local anodyne in *rheumatic and neuralgic complaints*, and *gout*. Seldom employed in medicine.

Stium latifolium, Linné; *Water parsnip*.—Europe and California. Root contains a poisonous resin, volatile aromatic oil, and a volatile base (analyzed by A. R. Porter and N. Rogers), and said to resemble the *pastinacine* of Wittstein (see *Amer. Jour. Pharm.*, 1876, pp. 348 and 483). Reputed narcotic and has been employed in *skin diseases*.

Stium lineare, Michaux, of North America, and *Stium angustifolium*, Linné, of North America and Europe, are similar plants and poisonous.

Stium nodiflorum, *Water parsnip*.—A European umbelliferous, aquatic perennial, the juice of which was found to be useful in various *cutaneous affections*, was formerly regarded as poisonous. The dose of the juice as given by Withering, however, was 3 or 4 ounces daily. It is diuretic and exerts a good influence upon *scrofulous lymphatic enlargements*. This plant is also found in the southern states.

Stium sisarum, *Skirret*.—Habitat China, cultivated in Europe, where it is eaten as a salad. Its root is sweetish and aromatic. Recommended as a diet in *pulmonic complaints*.

Ammi Visnaga, Lamarck; *Tooth-pick plant*.—South Europe, north Africa, and east Asia. This aromatic plant yields a bitter, crystalline, colorless glucosid, called *kelline*, isolated in 1878 by Ibrahim Mustapha. Th. Malosse, in 1881, found 2 per cent of an oily, acrid principle which he called *visnagin*; 3 crystalline, partly alkaloidal principles, collectively named *vismagin*; a fixed oil (10.5 per cent) containing *ammietearic acid*, etc. (*Amer. Jour. Pharm.*, 1881, p. 640, and 1886, p. 300). Kelline occasions vomiting, impeded respiration and cardiac irregularity. This plant is the *El Kellah* of the Moors. An 8 per cent decoction of the seeds, taken internally, is reputed to be a cure for troubles dependent on a uric acid diathesis, especially *rheumatism*. It relieves pain in the kidneys and urinary tract by its obtunding powers. Locally, this decoction has been applied in *rheumatism of the joints* to allay pain, and as a wash for *buccal ulcerations*.

Anthriscus Cerefolium, De Candolle (*Scandix Cerefolium*, Linné; *Cherophyllum sativum*, Lamarck); *Chervil*.—A European annual raised in gardens and used for greens. A volatile oil gives to the plant a strong, but pleasant odor, and a sharp, yet feebly bitterish taste. Externally, it has been applied to *bruises*, *swollen mammary glands*, and other local *tumefactions*; internally in *phthisis*, *scorbutus*, *scrofula*, *dropsy*, and *cutaneous disorders*. It is diuretic, emmenagogue, and deobstruent. Like other species of *Cherophyllum*, its leaves are sometimes collected for conium, though the plants do not greatly resemble each other.

CONTRAYERVA.—CONTRAYERVA.

The root of *Dorstenia Contrayerva*, Linné, and *Dorstenia brasiliensis*, Lamarck. *Nat. Ord.*—Urticaceæ.

Botanical Source.—*Dorstenia Contrayerva* is a perennial caulescent plant, with a spindle-shaped root, from which arises a stem covered with spreading, green, caly stipules. The leaves are palmate; the lobes lanceolate, acuminate, coarsely

serrated and gashed, and occasionally almost pinnatifid. The receptacle is borne on a very long stalk, and is quadrangular, wavy, or plaited. The achenia are lenticular, and imbedded in the fleshy receptacle from which they are projected with elasticity when ripe (L.). The *Dorstenia brasiliensis* closely resembles the preceding.

History and Description.—These plants inhabit the tropical parts of South America. The root, which is the part used, is knotty and ovoid, woody, 1 or 2 inches long, of a reddish-brown color externally, and pale within; its diameter is about $\frac{1}{2}$ an inch, and long, rough, slender fibers shoot out from all sides of it, especially its lower portion, and are generally loaded with small, brown knots. It has a peculiar aromatic odor, and a somewhat astringent, warm, bitterish taste, with some acidity when long chewed. As the fibers have but little odor or flavor they should be removed from the rhizome. It yields its virtues to alcohol, or water, at 100° C. (212° F.); the root abounds in mucilage; its tincture has an acid reaction on litmus.

The root of commerce is probably derived from several other species, which possess similar virtues, as the *D. Houstoni*, *D. dracena*, *D. tubicina*, and *D. opifera*. Monardes states that the word *contrayerva* is the Indo-Spanish term for alexipharmic or counterpoison.

Chemical Composition.—According to Geiger, the root contains volatile oil, starch, and a non-crystalline bitter, to which may be added resin, free acid, and woody fiber.

Action, Medical Uses, and Dosage.—Contrayerva is a gentle stimulant and a diaphoretic, and is sometimes given in *exanthematous diseases*, *typhus fever*, and *dysentery*. Its dose, in powder, is 30 grains; the best form of administration is the infusion. The Virginia snake-root is preferred to it in this country.

CONVALLARIA (U. S. P.)—CONVALLARIA.

"The rhizome and rootlets of *Convallaria majalis*, Linné"—(U. S. P.).

Nat. Ord.—Liliaceæ.

COMMON NAMES: *Lily of the valley* (*Lilium convallium*), *May lily*.

Botanical Source.—This plant is a low, glabrous, stemless, perennial herb, with a much-branched, slender, creeping, whitish rhizome, sending up from a bud 2, sometimes 3 oblong or ovate-elliptic leaves, the petioles of which are long and sheathing, and rolled together so as to appear stalklike. The flowers are borne on an angular scape, in the form of a raceme, and are handsome, fragrant, nodding, bell-shaped, and waxy-white in color. The perianth has a recurved lobes, and is deciduous; the stamens, 6 in number, are inserted at the perianth-base. The style is stout and single, and the stigma triangular. The fruit is a few-seeded, red berry.

History and Description.—This beautiful wild flower is indigenous to Siberia, and to a large part of Europe, from the Mediterranean northward, and is found in the mountainous woods of our own country from Virginia to the Carolinas and Georgia. It blooms in May and June. The cultivated flower is somewhat larger than that of the wild species, and is a general favorite on account of its beauty and fragrance. All parts of the plant are possessed of medicinal properties, the rhizome alone being official. It is described as follows: "Of horizontal growth and somewhat branched, about 3 Mm. ($\frac{1}{8}$ inch) thick, cylindrical, wrinkled, whitish, marked with few circular scars; at the annulate joint with about 8 or 10 long, thin roots; fracture somewhat fibrous, white; odor peculiar, pleasant; taste sweetish, bitter, and somewhat acrid"—(U. S. P.). The flowers have a bitter, acrid taste, and the root is best when gathered in August.

Chemical Composition.—The flowers of this plant contain a crystalline, odorous body, isolated in 1835 by Herberger. So powerful is its odor that headache is said to be induced by it. When much diluted it is extremely fragrant.

Convallaria majalis.

Two glucosids were found in the root and herb by G. F. Walz in 1858 (*Amer. Jour. Pharm.*, 1859, p. 557). The first is *convallamarin* ($C_{22}H_{34}O_{11}$). It occurs as a very bitter, subsequently sweetish, amorphous or imperfectly crystalline powder, insoluble in ether, but soluble in amyl alcohol and chloroform, alcohol, wood alcohol and water. Heated with diluted acids it splits into *convallamarinetin* and sugar. The second glucosid is *convallarin* ($C_{22}H_{34}O_{11}$), the acrid principle, occurring in rectangular, prismatic crystals, which, although but little soluble in water, impart to the solution an acrid taste, and cause it when agitated to foam as if saponin were present. Alcohol readily dissolves it, while ether does not. Heating with diluted acids causes it to split into *convallaretin* and sugar. (See Buchner's *Rep.*, 1835, p. 397, and Husemann and Hilger, 1884.)

Action, Medical Uses, and Dosage.—In its effects upon the human circulatory system, convallaria very closely resembles digitalis, without, however, causing the unpleasant disturbances produced by the latter. Besides its effects upon the heart it acts upon the gastro-intestinal tract, producing emesis or purgation. The entire plant should be used to get the best effects, the flowers alone having been found quite inert. It seems well established that the failures attributed to this drug have been largely due to the poor preparations used, for it is certainly true that representative preparations have a pronounced action upon the economy. Convallamarin is decidedly toxic, death having promptly occurred from suspension of the heart action when introduced directly into the veins of the rabbit. The powdered flowers are sternutatory, and have been used in fomentations for the removal of *ecchymosed spots* caused by bruises. *Epilepsy*, *worms*, and *miasmatic fevers* have been treated with the root. The chief use of convallaria, however, is that of a heart remedy. Owing to its controlling action upon the heart it acts secondarily as a diuretic and was first employed in *dropsy* for this purpose by the Russians. Like digitalis, it is useful in those cases of dropsy where the *cardiac debility* is such that there is imperfect circulation through the organ itself, and where there is evidence of obstruction. Palpitation and irregular movements, dyspnoea, diminished renal action with increase of solids in the urine, hepatic fullness and engorgement, and oedema, are usually symptoms of this form of cardiac inefficiency. The cases of dropsy benefited, therefore, are those of cardiac origin with feeble circulation and diminished blood pressure. In small doses convallaria is a tonic to the heart, strengthening its action. *Cardiac excitation* is relieved by moderate doses, while large doses increase the heart action. Medium-sized doses are recommended in the early stage of *carditis* (Webster). *Mitral insufficiency*, with the attendant dyspnoea and palpitation, is considered as a proper condition for the exhibition of convallaria. When the favorable action upon the heart and vessels begins the heart-beats become slower, normal rhythm is established, heart power is increased, arterial pressure is augmented, respiration deepened, and the suffocative sensation, with the distressing and painful desire for air, is dispelled. Convallaria should be thought of in the *cardiac debility* following severe and exhaustive diseases, such as *typhoid fever*, *la grippe*, etc. It tends to promote a normal circulation, and relieves that sense of præcordial faintness which is apt to follow prostrating conditions. Convallaria has had no bad effects upon the cerebro-spinal tract, nor upon the digestive organs. In fact it is rather a tonic to the latter, increasing the appetite and digestive power, and acting slightly as an aperient.

Compared with digitalis, convallaria is generally as efficient, both as a heart tonic and as a diuretic, and in many cases is said to act better. It is safer than digitalis, which may destroy life by paralyzing the heart, an effect never produced by convallaria. Moreover, it is freer from cumulative effects. Vomiting, anorexia, disordered digestion, cerebral excitation, and pupillary dilatation, in addition to its acrid taste, make digitalis often an unpleasant remedy. Convallaria is free from these objections, and may be substituted whenever the former has to be withdrawn.

It should be borne in mind that the heart irregularities benefited by this drug are not those due to organic degeneration so much as those of an obstructive character, due to mechanical causes, and particularly where the mitral valves are involved. *Insufficiency or stenotic conditions of the aorta* are less benefited than mitral complications. While it may be said that convallaria is never contraindicated in

proper doses, it is, however, more particularly designed, according to Prof. Scudder, "to lessen the frequency of the pulse when there is an impaired capillary circulation, as shown by ecchymosis, or by the slow return of blood when it is effaced by the finger" (*Spec. Med.*). *Rheumatism*, when associated with disordered circulation, has been relieved by it. The aqueous extract of the whole plant in doses of from 15 to 20 grains a day, is said to be an efficient form of administration (Germain-Seè); the dose of the infusion of the whole plant (3i to water fl̄iv) is ½ fluid ounce; of the fluid extract, 5 to 15 drops; the tincture, 5 to 30 drops; specific convallaria, 2 to 10 drops 4 times a day; convallamarin, from ¼ to 1 grain.

Specific Indications and Uses.—Heart irregularities due to mechanical impediments; mitral insufficiency; dropsy of cardiac origin; palpitation and vehement heart action, with arrhythmic movements, dyspnoea, and diminished arterial pressure. Quickened pulse with capillary obstruction.

Related Species.—*Polygonatum biflorum* (Walter), Elliott. *Convallaria biflora*, Walter. *Hairy Solomon's seal*, *Smaller Solomon's seal*. Formerly the species named as growing in the

Fig. 84.
1. *Polygonatum biflorum*.
2. *Vagnera racemosa*.

United States, and as being used medicinally, was indicated as *Convallaria multiflora* of Linné, or *Polygonatum multiflorum* of Desfontaines. The only species of *Polygonatum*, however, growing in the United States in the territory ascribed to the preceding, are the *Polygonatum biflorum*, Elliott, and the *Polygonatum commutatum* (R. & S.), Dietrich. The former is from 8 inches to 3 feet high, and has the under surface of the leaves pubescent. It thrives in woods, on high banks, hillsides, mountains, and in thickets, from New Brunswick to Ontario and Michigan, southward to Florida and West Virginia, and westward to Kansas and Texas. It blooms from April to August.

Polygonatum commutatum (R. & S.), Dietrich (*Polygonatum giganteum*, Dietrich; *Convallaria commutata* [R. & S.]); *Smooth Solomon's seal*, *Great Solomon's seal*, *Giant Solomon's seal*.—A glabrous species seldom found in dry situations, but thriving in moist woods and along streams from Rhode Island to Ontario and Manitoba, southward to Georgia and Louisiana, and westward to Utah, New Mexico, and the Rocky Mountains. It

blooms from May to August, and is quite variable both in size and in the form of its leaves.

Vagnera racemosa, Morong; *Convallaria racemosa*, Linné, *Smilacina racemosa*, Desfontaines; *Pulse Solomon's seal*, *Spiked Solomon's seal*, *False spikenard*.—Common in copses in the United States. Rhizome thick, sweet, with a stem from 1 to 2 feet high, downy, and recurved at the top. Leaves from 4 to 6 inches long, about one-third as broad, oval, acuminate, veined, minutely pubescent, on petioles not exceeding 2 lines in length, often sessile. The flowers are very numerous, small, white, on white pedicels, with white, exserted, tapering filaments, constituting a large, compound, terminal raceme. Berry 3-celled, pale-red, speckled with purple, aromatic (W.—G.).

The rhizomes of the foregoing plants are inodorous, but of a mucilaginous, somewhat sweetish taste, followed by a faint sense of bitterness.

The name *Solomon's seal* is derived from the peculiar seal-like scars left upon the rhizome by the decay of the stems of the previous year's growth. The *True Solomon's seal* is derived from the *Polygonatum multiflorum*, Allioni (*Convallaria multiflora*, Linné), and *Polygonatum officinale*, Allioni (*Convallaria Polygonatum*, Linné). Indigenous to Europe, northern Asia, and Afghanistan. Their rhizomes and plants yielded (Walz) pectin, sugar, starch, mucilage, asparagin, and convallarin.

Although used with asserted benefit in several diseases by many physicians, yet the American species of these plants have received but little attention as to their true therapeutic characteristics. They are reputed tonic, mucilaginous, and mildly astringent, exerting a specific influence upon irritated and relaxed mucous membranes. Of much value in *leucorrhœa*, *menorrhagia*, *female debility*, and *pectoral affections*. In *piles*, the root chewed and swallowed, or a decoction drank as freely as the stomach will bear, will give prompt relief, or the root may be applied to the part with a similar result. An infusion of the root will be of great efficacy in irritable conditions of the intestines, as well as in *chronic inflammations* of these parts, especially when attended with burning sensations, pain, etc. In *erysipelas* and *cutaneous affections* of an erysipelatous nature, as well as those maladies of the skin produced by the *poison-vine*, or resulting from the poisonous exhalations of other plants, the decoction of Solomon's seal root will afford direct relief, and an ultimate cure. It may also be applied externally, with advantage, to *local inflammations*. A large dose of the decoction will often provoke emesis or nausea, and act as a cathartic. Dose of the decoction, from 1 to 4 ounces, 3 times daily. Solomon's seal 4 ounces, water 2 pints, molasses 1 pint, simmered down to 1 pint, then strained and evaporated to the consistence of a thick fluid extract, and 1 ounce or ½ ounce of powdered resin mixed with it, in doses of 1 teaspoonful several times a day, forms an excellent remedy for *piles*. The rhizomes of the various species may be used collectively under the term *Solomon's seal*.

Zygadenus venenosus, Watson. *Nat. Ord.*—Liliaceæ. Northwestern states. The poisonous bulb of this species, according to Watson, is known to the northern Indians of this country

as *Death camass*. Violent spasms have been observed by Dr. S. H. Goodell from the ingestion of the plant. Several members of this genus are accredited with poisonous qualities.

TULIPINA.—Alkaloid of *Tulipa Gesneriana*, or *Garden tulip*. A cardiac poison with pronounced sialogogue properties.

COPAIBA (U. S. P.)—COPAIBA.

"The oleoresin of *Copaiba Langsdorffii* (Desfontaines) O. Kuntze, and of other species of *Copaiba*"—(U. S. P.).

Nat. Ord.—Leguminosæ.

COMMON NAMES: *Copaiba*, *Capivi*, *Balsam of copaiba*, *Balsam of copaiba*, *Balsam capivi*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 93.

Botanical Source.—The genus *Copaiba* is composed of handsome shrubs or trees (most of them middle or large-sized), clothed with abrupt, pinnate, leathery leaves, and adorned with apetalous blossoms borne in whitish racemes. The fruit is a coriaceous legume, containing a single seed. The official species varies considerably in the size and form of its leaflets, and may itself be only a shrub, or a small, or a very large tree. It yields the oleoresin abundantly. The substance of the literature on copaiba may be given in the following fragment of an article contributed by us to the *Western Druggist*, Feb., 1898:

History and Collection.—Copaiba (popularly known as balsam of copaiba), is obtained from South America, principally from Brazil and Venezuela, being produced by numerous species of the genus *Copaifera*. According to Flückiger, the following species are the principal sources of the copaiba of commerce: (1) *Copaifera officinalis*, Linné, (Guiana, Venezuela, Colombia, Trinidad); (2) *Copaifera guianensis*, Desfontaines (Lower Amazon, lower Rio Negro, Cayenne, Surinam); (3) *C. coriacea*, Martius (Bahia and Piahy); (4) *C. Langsdorffii*, Desfontaines (continental provinces of Brazil). The number of known species has steadily increased until now the *Index Kewensis* recognizes 23 American and 5 African species.

The copaiba obtained from the vast territory of the Brazilian continent, along the Amazon and its tributaries, is collected in the shipping port of Para. Maranhao Island is also a place of export. Other shipping ports are Maracaibo and Angostura in Venezuela; Trinidad, Demerara (British Guiana), Cartagena (Colombia), and Rio de Janeiro.

As to the mode of collecting the balsam, Piso (1658) relates that an incision is made through the bark deep into the pith at the season of the full moon, which causes such an abundant flow of fatty and oily liquid that 12 pounds may exude in 3 hours. In case no oil should appear, the opening is at once closed with wax or clay, and after 2 weeks the yield is sufficient to make up for the delay. The fact that the resiniferous ducts in these trees often attain a diameter of 1 inch, as has been observed more recently by Karsten, seems to be quite in harmony with the statement regarding the abundant yield. It is also related that frequently the balsam accumulates in these ducts and exerts pressure enough upon the enclosing walls to burst the tree with a loud report. According to Piso, the copaiba tree is not very frequent in the province of Pernambuco, but thrives luxuriantly in the island of Maranhao, which he says furnishes the balsam of commerce in great quantity. He also enumerates the many medicinal virtues of the balsam, making the curious statement that its healing virtues are also experienced as an efficient means to check the flow of blood in the Jewish practice of circumcision.

Labat reports that in 1696 he had an opportunity to observe for the first time the tree yielding copaiba in the island of Guadeloupe. He relates in detail the manner of collecting the balsam which he calls *huile de copau*. The vessels in which the balsam is collected are made of the fruit of the calabash, a kind of gourd. The collection, he states, takes place about 3 months after the rainy season; that is, in March for the countries north of the equator, and in September for the countries south of this line. The balsam, he states, closes all kinds of wounds except those inflicted by gunshot. He declares it to be a powerful febrifuge, having been used with almost marvelous effect in the fever epidemics at Rennes and Nantes in 1719.

Description and Chemical Composition.—The *U. S. P.* describes copaiba balsam as "a transparent or translucent, more or less viscid liquid, of a pale-yellow to brownish-yellow color, having a peculiar, aromatic odor, and a bitter and acrid taste. Specific gravity 0.940 to 0.990 at 15° C. (59° F.). Insoluble in water, readily soluble in absolute alcohol, ether, chloroform, carbon disulphide, benzin, and fixed and volatile oils. It yields a transparent mixture with one-third of its volume of ammonia water"—(*U. S. P.*). Copaiba has the property of solidifying when triturated with 6 per cent of its weight of calcined magnesia (mass of copaiba, *U. S. P.*). According to Roussin the condition necessary to bring about solidification is the presence of water, either in the balsam or in the base. When both bodies are anhydrous the balsam remains liquid. In this connection it may be said that the process of the *U. S. P.* (and of other pharmacopœias as well), for making solidified copaiba directs the magnesia to be previously triturated with a little water. Two varieties of copaiba are distinguished in commerce; the *Para variety* from Brazil, a thin, clear, pale, aromatic, somewhat acrid and bitter fluid; and the *Maracaibo variety*, from the Antilles and the adjacent parts of the continent, a thick, golden-yellow, sometimes faintly fluorescent oil, having an odor suggestive of turpentine.

Balsam of copaiba, so-called, is not a balsam in the strict sense, for the term balsam is properly applied to such resinous exudations as contain the aromatic principles benzoic or cinnamic acid, both of which are absent in copaiba. Copaiba is an oleoresin, consisting of a volatile oil, which holds a non-volatile resin of acid properties in solution. The proportion of oil varies considerably with the different specimens, ranging from 30 to 60 per cent, sometimes being as high as 80 per cent, or even more. Both the oil and resin have been investigated (see *Oleum Copaibæ*). The residue remaining after distilling the essential oil is a hard and brittle resin which softens on warming. It dissolves in alcohol, benzin, and amyl alcohol, and consists mostly of amorphous acids. *Copaivic acid* ($C_{20}H_{20}O_4$), is a crystallizable substance which sometimes occurs as a deposit when balsam of copaiba is kept for a long time. It was first obtained by Schweitzer, in 1829. Flückiger observed a similar deposit in Trinidad balsam, from *Copaifera officinalis*, which he thought identical with copaivic acid. Fehling, in 1841, obtained a crystalline deposit from *Para copaiba* which differed from copaivic acid, and gave it the name *oxycopaivic acid* ($C_{20}H_{18}O_4$). From *Maracaibo copaiba*, Straus, in 1865, isolated another crystalline acid of the formula $C_{20}H_{18}O_4$, which he called *metacopaivic acid*. It melts at 205° C. (401° F.). All these crystalline, resinic acids and a peculiar principle discovered by Flückiger, have a bitterish taste. The closer chemical study of the oleoresin is beset with many obstacles, owing to the difficulty of procuring authentic specimens, as well as to the great variation in the product itself, due to its being collected from different species, or even different trees, and also to the possibility of sophistications not easily to be recognized.

Adulterations and Tests.—Probably the most frequent adulteration of the balsam is that of turpentine, which is facilitated when the pharmacopœial demand calls for the more viscid variety of the balsam. The *U. S. P.* mentions the following tests: "When copaiba is heated it should not evolve the odor of turpentine. When the volatile oil has been completely driven off by heating copaiba in a flat-bottomed capsule, the residue, when cold, should be amorphous, transparent, and friable (absence of fixed oils). Copaiba should not be fluorescent, and, when heated to 130° C. (266° F.), it should not become gelatinous. On adding 1 drop of copaiba to 19 drops of carbon disulphide, and shaking the mixture with 1 drop of a cold mixture of equal parts of nitric and sulphuric acids, it should not acquire a purplish-red or violet color (absence of gurgun balsam)"—(*U. S. P.*). The *German Pharmacopœia*, 3d ed. (additions), introduces two tests for colophony (suggested by Gehe & Co.), the second, the more sensitive, being as follows. "Expel the essential oil by heating on the water-bath, pulverize the residual resin, and dissolve 1 part in 5 parts of ammonia water. The cloudy solution should not gelatinize even after 1 day's standing." This test is said to detect about 10 per cent of colophony. See also Bosetti, *Chem. Ztg.*, 1896, p. 846.

The absence of fixed oils in copaiba is indicated, according to the *U. S. P.*, if upon complete evaporation of the volatile oil, the residue, when cold, becomes amorphous, transparent and friable. One of the direct tests for castor oil is based

upon its insolubility in petroleum benzin, while copaiba, in excess of the solvent, is completely soluble, save a flocculent precipitate. However, it requires the addition of at least 10 volumes of petroleum benzin (Maisch, *Amer. Jour. Pharm.*, 1877, p. 131), for the precipitation of part of the admixed castor oil. Flückiger and Hanbury's test for the presence of castor oil is to heat the copaiba with 4 parts of alcohol (85 per cent); cool; evaporate the upper of the two layers formed, which contains alcohol, castor and essential oils, when the odor of castor oil will be evolved. If caustic lime or soda be heated with it cenanthol will be formed, which may be recognized by its characteristic odor. This will detect even 1 per cent of the adulterant (*Pharmacographia*).

Another possible (perhaps probable) admixture is that of gurjun balsam, or wood oil, obtained from various species of gigantic trees (*Dipterocarpus*), native to India. (According to Mr. Kebler about 30,000 pounds of gurjun balsam were imported in 1894 without any authentic information being obtainable concerning its disposition). This balsam has the property of thickening when heated to 130° C. (266° F.), especially in closed tubes. Mr. L. F. Kebler has employed with much satisfaction the following test suggested by Messrs. Dodge and Olcott, for the presence of gurjun balsam in copaiba: "Place 1 Cc. of glacial acetic acid (99.5 per cent) in a test-tube; to this add 4 drops of pure concentrated nitric acid (sp. gr. 1.42); mix well; then add to this mixture, carefully, 4 drops of the balsam in question; if gurjun balsam is present, within 5 minutes a reddish zone will appear between the layer of balsam and the acid. On mixing the contents of the test-tube well, the whole will assume a reddish or purple color." Another test, by which it is claimed that 1 per cent of gurjun balsam may be detected, is given by Ed. Hirschsohn (*Jahresb. der Pharm.*, 1895), and consists in heating a mixture of 1 volume of the balsam, 3 volumes of 95 per cent alcohol, and 1 gramme of stannous chloride. If gurjun balsam is present a pink coloration appears, becoming violet-red after $\frac{1}{2}$ hour, but after 1 hour's standing its vividness disappears.

In testing copaiba the *German Pharmacopœia* (1890) introduces directions for the determination of the acid number and the ester number, calculated to detect an admixture of colophony and compound ethers (or esters).

Action, Medical Uses, and Dosage.—When given in large doses, copaiba is an irritant; in medicinal doses it is stimulant, cathartic, and diuretic; it likewise exerts an especial influence on the mucous tissues of the system, diminishing their secretions when excessive, and for this latter purpose it is principally employed. Taken internally, it causes warmth in the gastric region, with unpleasant eructations, and sometimes nausea, or even emesis. Its continued use, unless in very small doses, impairs the digestive functions. In the course of its action it becomes absorbed, so that its odor and bitter taste are communicated to the urine, while the former can also be observed in the respiration. Among the inconveniences attending its use, especially in large doses, the most frequent are sickness at stomach, emesis, hematuria, catharsis, and febrile symptoms; these effects may be obviated very often by administering the remedy more frequently, but in smaller doses, and by combining it with cinnamon, nutmeg, or some other aromatic. At times it produces a transient, papular, cutaneous affection, like the eruption of rubeola, and which is accompanied with an unpleasant formication or itching. It has been found most beneficial in chronic mucous affections, as in *chronic gonorrhœa*, *bronchitis*, *irritable conditions of the bladder*, *gleet*, *leucorrhœa*, *chronic catarrh*, *chronic diarrhœa* and *dysentery*, and *obstinate piles*. Its effects in gonorrhœa are much improved by the addition of liquor potasse; and is much more beneficial in the gonorrhœa of males than of females, because, in the latter, the vagina is oftener affected than the urethra. However, in the urethral form it is equally as efficient in both sexes. It seems necessary that the copaiba-impregnated urine pass over the infected parts, and for that reason it is seldom as effectual in injection as when taken internally. According to Prof. F. J. Locke it has a specific influence if properly used, and that in all stages of the disease it has been used in too large doses. In the inflammatory stage of gonorrhœa, with great urethral irritation and profuse discharge, it is always contraindicated. In this acute stage he recommends the following as a sedative: "R Specific aconite, grtt. x; specific gelsemium, specific cannabis, aa flzj; simple syrup, aqua, aa q. s. flziv. Mix. Dose, a teaspoonful every 3 hours, or 4 teaspoonfuls per day."

If the urination produce burning, give in a wineglassful of water from 10 to 15 grains of sodium bicarbonate, 2 or 3 times a day; if constipated, purge with compound powder of senna and jalap. Then, in the latter stage, in the absence of inflammation: R Copaiba, fl3j; alcohol, fl3j. Mix. Dose, 5 to 10 drops, 4 times a day in sugar and water. When the disease is chronic or unduly prolonged: R Copaiba, sweet spirit of nitre, aa fl3ss; liquor potassæ, essence of cinnamon, aa fl3j; mucilage of acacia, simple syrup, aa fl3j. Mix. Dose, a teaspoonful after each meal (Locke's *Syllabus*, p. 110). However, the more recent improvements in the treatment of gonorrhœa (especially the course above pursued in the acute form), render the disease readily curable, copaiba being rarely, if ever, required to effect the cure. In injection, it has been used with fairly good results. Make an emulsion of 2 drachms of copaiba with the yolk of an egg, add 20 or 30 drops of laudanum to it, in order to prevent its too speedy discharge from the rectum, and 8 fluid ounces of water. This may be used as a rectal injection, and repeated 3 or 4 times a day. In small doses (5 drops) copaiba is useful in *chronic inflammation of the intestinal tract with ulceration*. Give the medicine 3 times a day. Locally, it forms an excellent application to *chilblains, sore nipples, old ulcers, and fistulous ulcers*, in which it serves to speedily soften the callosity of the walls of the fistulous canal. *Vesical catarrh, painful dysuria, and irritable bladder*, from excessive venery, or following gonorrhœa, are relieved by taking from 1 to 5 drops of copaiba on sugar. Inflammation of the urinary passages contraindicates its use.

Painted upon the breast in *mastitis*, and covered with oil silk, it often prevents the formation of abscesses. It has been painted upon the cheeks and temple for the relief of *purulent ophthalmia, syphilitic iritis, and scleritis*. *Scaly diseases of the skin* have also been influenced for good by its internal use. The dose of copaiba is from 5 to 60 drops, 2 or 3 times a day. It may be taken in emulsion, made by triturating each dose with the yolk of 1 egg, adding $\frac{1}{2}$ an ounce of mint, cinnamon, or other aromatic water, and sweetening with sugar, or it may be taken in the form of pill with magnesia. The best and least objectionable form in which it can be taken is in the form of capsules. The oil (which see) is the best form for obtaining the effects of copaiba upon the respiratory tract.

Specific Indications and Uses.—Vesical pressure and tenesmus, frequent desire to urinate, the urine coming in drops; itching, burning, or smarting in urethra after urination; urethral mucoid discharges; cough, with thick tenacious expectoration, accompanied by loud mucous rales; laryngeal irritation.

Related Products.—OLEORESIN OF HARDWICKIA. This is a product of the *Hardwickia pinnata* of Roxburgh, *Nat. Ord.*—Leguminosæ, and closely resembles copaiba in taste and odor. It is, however, of darker color, and, though transparent, appears black when viewed with reflected light. It is thick and viscid, and is not fluorescent like *gurjun balsam*, and, in transmitted light, is pale yellowish-green in thin layers and wine-red in thicker layers. Broughton obtained a considerable amount of volatile oil (25 to 40 per cent), identical in composition with copaiba oil, though he failed to find copaivic acid in the resinous portion, which probably consists of two resins, one of which has acid qualities. The oil has lævogyre properties. This oleoresin comes from the East Indies, and is collected exactly like copaiba in Brazil. On applying the above pharmacopœial test for the presence of *gurjun balsam* in copaiba to the oleoresin of hardwickia, a faint greenish-yellow hue results. In India this oleoresin is employed in *gonorrhœa* with as good results as are obtained from copaiba.

LAGAM BALSAM (*Minjak-lagam*).—A product resembling balsamum dipterocarpi, and having a bitter, persistently acrid taste. It is of greenish cast in reflected, and transparently yellow in transmitted light. It readily dissolves in alcohol, benzol, ether, carbon disulphide, and chloroform. A lævogyre essential oil ($C_{20}H_{32}$), to the extent of $\frac{1}{3}$ of the balsam, was obtained by G. Haussner by distillation with water. There are two resins present, one neutral and the other acid. The acid resin ($C_7H_4O_2$) is amorphous. When melted with caustic potash the neutral resin yields acetic, formic, butyric, and other acids and phenols. It was introduced into Europe from Sumatra, in 1854, but its botanical source is unknown (*Amer. Jour. Pharm.*, 1883, p. 369, from *Archiv. der Pharm.*, 1883).

COPTIS.—GOLD-THREAD.

The rhizome and rootlets of *Coptis trifolia*, Salisbury (*Helleborus trifolius*, Linné).

COMMON NAMES: *Gold-thread, Mouth-root, Canker-root.*

ILLUSTRATIONS: Lloyd's *Drugs and Med. of N. A.*, Vol. I, Pl. 18; Bentley and Trimen, *Med. Plants*, 3.

Botanical Source.—This plant has a small and creeping, slender, thread-like, perennial rhizome of a bright-yellow color. Its leaves are ternate, on long, slender petioles, evergreen, and radical in tufts and invested at the base with a number of ovate, acuminate, yellowish scales. The leaflets are roundish, acute at base, lobed, and renate, smooth, firm, veiny, sessile, and 4 to 8 lines long; the crenatures acuminate. The scape is slender, round, bearing 1 small, starry, white flower lower, and a minute, ovate, acute bract at some distance below. Petals 5, 6, or 7, inversely conical, hollow, and yellow at the mouth. Sepals 5, 6, or 7, oblong, concave, and white. Stamens numerous, white, with capillary filaments, and adnate, roundish anthers. Ovaries from 5 to 7, stipitate, oblong, and compressed. The styles are short and recurved; the stigmas acute. The capsules are stalked, oblong, ostrate, and compressed, diverging stellately, and containing many small, black, oval seeds (L.—W.).

Coptis trifolia.

History.—Gold-thread is found growing in the northern parts of the United States, following the Appalachian range as far south as northern Alabama, and in Canada, Greenland, Iceland, and Siberia. It grows in dark swamps and phaginous woods, flowering from early in the spring to July. "Northern cedar and spruce and balsam swamps always abound with it. Another favorite habitat of the plant is the cold swamps, such as are found in mountain plateaus. It often grows freely in beds of sphagnum and other mosses, especially in wooded swamps. Although coptis is a *swamp* plant, it is not a *mud* plant, but generally selects the dry knolls surrounded by wet soil" (C. G. Lloyd, *Drugs and Med. of N. A.*, Vol. I, p. 195). At one time it was so popular as a domestic remedy that more of it was sold in Boston than almost any other indigenous drug (Bigelow). It is now but little employed. Autumn is the season for collecting coptis, when it should be dried with care. Its properties are imparted to water, but more perfectly to alcohol, and the solutions are precipitated by nitrate of silver and acetate of lead.

Description.—Coptis "appears in market as masses of the entire plant, in which the bright-yellow, thread-like rhizome preponderates, and this yellow color is often perceptible part way up the leaf-stalk. The rhizome is pure bitter to the taste (berberine), and the portion of the leaf-stalk that possesses a yellow color is also perceptibly bitter. The other portions of the plant are insipid" (J. U. Lloyd, *Drugs and Med. of N. A.*, Vol. I, p. 198). It is also odorless.

Chemical Composition.—Coptis does not appear to contain resin, gum, gallic acid, or tannin, its virtues depending, probably, on its two alkaloids. In 1862, Prof. John M. Maisch (Buchner's *Neues Repert. of Pharm.*, Vol. XI) announced *berberine* as its bitter principle, which was later confirmed by Prof. F. F. Mayer (1863), E. Z. Gross (1873), and J. J. Schultz (1884). Prof. Mayer also announced that the berberine was associated with another alkaloid, which was afterward obtained by both Gross and Schultz, the former naming it *coptine*. C. W. Burr (1884) found starch in the rhizome, though Gross had previously failed to do so. Sugar, albumen, and silica are also present in coptis. Coptine is a white, crystalline alkaloid, existing in the plant in small quantities (see *Drugs and Med. of N. A.*).

Action, Medical Uses, and Dosage.—Gold-thread is a pure and powerful bitter tonic, somewhat like quassia, gentian, and calumba, without any astringency. It may be beneficially used in all cases where a bitter tonic is required, and is decidedly efficient as a wash or gargle, when in decoction, in various *ulcerations of the mouth*. In the *nursing sore mouth of mothers* we have repeatedly and promptly cured with the decoction when infusion of hydrastis had no effect. This would seem to indicate that its virtues are not wholly dependent upon berberine as is generally supposed. In *dyspepsia*, and in *chronic inflammations of the stomach*, equal parts of gold-thread and golden-seal, made into a decoction, with

elixir vitriol added in proper quantity, will not only prove effectual, but in many instances of the latter kind, will permanently destroy the appetite for alcoholic beverages. Dose of the powder, or tincture, from $\frac{1}{4}$ drachm to 1 drachm; of the decoction, from 2 to 6 fluid drachms; the tincture, made by adding an ounce of the powdered root to a pint of diluted alcohol, is preferable to the powder.

Related Species.—*Coptis occidentalis*, Torrey and Gray. This and the following plant are the more common species of *Coptis* found in the Rocky Mountain region and in the north-western states, this species being found in Washington, Idaho, Oregon, and western Montana (*D. & M. of N. A.*, Vol. I, 195-197).

Coptis asplenifolia, Salisbury.—High altitudes of northern half of Montana, Idaho, and Washington, and common in West British America. This and the above species contain berberine, and probably possess medicinal virtues similar to those of *Coptis trifolia* (*D. & M. of N. A.*, Vol. I, 195-197).

Coptis Teeta, Wallich, Tita.—This drug (known in the Indian bazars as *Mishmee bitter*, is exported from China into India, where it is used as a bitter tonic, and locally in conjunctival diseases. The root is also used in India in visceral obstructions, flatulence, jaundice, and toothache (*Dymock, Mat. Med. Western India*).

Coptis anemonesifolia, Siebold.—Japan. Used like *Coptis* and contains berberine.

CORALLORHIZA.—CORAL-ROOT.

The rhizome of *Corallorhiza odontorhiza*, Nuttall.

Nat. Ord.—Orchidaceæ.

Common Names: *Crawley*, *Coral-root*, *Dragon's claw*, *Chicken-toe*.

Botanical Source.—This is a singular, leafless plant, with much-branched and toothed, coral-like root-stalks. The rhizome is a collection of small, fleshy tubers, articulated and branched much like coral. The scape is from 9 to 14 inches high, rather fleshy, striate, smooth, and invested with a few long, purplish-brown sheaths. The flowers are from 10 to 20 in number, ringent, in a long spike of a brownish-green color. The lip is white, generally with purple spots, undivided, oval, obtuse, and crenulated; the spur obsolete and adnate to the globular ovary; the anther 2-lipped and terminal; pollen-masses 4, obliquely incumbent. The capsule is large, reflexed, strongly ribbed and oblong, or subglobose (*G.—W.*).

History.—This plant is indigenous to the United States, growing in rich woods, about the roots of trees, from Maine to Carolina and westward to the east bank of the Mississippi River, flowering from July to October. Not very common south of 35° or 36° latitude. The species *C. multiflora*, *C. Wisteriana*, *C. innata*, and *C. Macræi* probably possess similar medicinal virtues. The rhizome of the first-mentioned species (*C. multiflora*, Nuttall), which grows as far west as the Rockies, is undoubtedly often present in the commercial drug, and is probably as valuable. It differs from the above species somewhat, especially in having in its spike from 15 to 25 or 30 flowers, which have a deeply 3-cleft lip, and are spurred, and are succeeded by a pendulous, elliptical capsule, instead of a roundish one. The plant is also much stouter. It was first discovered in 1816, by Dr. D. S. C. H. Smith, although long known previous to that time to herbalists. The entire plant is destitute of verdure. The root is the medicinal part; it is small, dark-brown, resembling cloves or a hen's claw, has a strong, nitrous smell, and a mucilaginous, slightly bitter, astringent taste. It has not been analyzed.

Description.—The dried root, as met in commerce, is composed of small, coral-like pieces, about 2 lines in diameter, and from 3 to 12 lines long, the longest pieces consisting of the small, coral-like branches, round or compressed, crooked, wrinkled lengthwise, more or less distinctly annulated at distances varying from 1 to 2 lines, dark-brown externally, and lighter within. Its fracture is short, presenting under the microscope a shining, pulverulent, or granular appearance, somewhat like the saccharine frost on figs and raisins. The root is inodorous, with a taste sweetish at first, somewhat resembling that of raisin-seed, and succeeded by a faintly bitterish, mucilaginous flavor.

Action, Medical Uses, and Dosage.—Crawley is probably the most powerful, prompt, and certain true diaphoretic in the materia medica, but its scarcity and high price prevent it from coming into general use. It is also sedative, and promotes perspiration, without producing any excitement in the system. Its chief value is as a diaphoretic, in fevers, especially typhus, and in inflammatory diseases; it has proved efficient in acute erysipelas, cramps, flatulency, pleurisy, and night-sweats; and relieves hectic fever without debilitating the patient. Probably it will be found to combine tonic, sedative, diaphoretic, and febrifuge properties. When, in acute pulmonic troubles, a non-stimulating diaphoretic is needed, we can employ none better than the coral-root. To "break up a cold" it is one of the most certain of medicines. It is fully equal to asclepias, and lacks the dangerous features of jaborandi. It has done excellent service in diphtheria. Acute and chronic pleurisy are both conditions in which it will prove curative. Years ago it was used for the control of colligative sweating of phthisis, and will be found equal to muscarine and salvia for this purpose. It is one of the best remedies ever employed for the general debility preceding pulmonic affections. We have employed tincture of coral-root in cases where all the symptoms were those of incipient consumption, with the most beneficial results. There is hacking cough, loss of weight, want of appetite, pleuritic pains, and marked general prostration. The remedy will be found slow, but certain in its action. From 3 to 5 weeks will be required before any good results can be observed. The appetite is the first to respond, the cough and pain cease, there is increased urinary product, and the functions of the skin are better performed. The patient increases in strength and flesh, and all the unfavorable symptoms disappear. It has been employed in dry bronchial irritation with "tightness across the chest, wheezing, and severe paroxysms of irritable cough," and in one case where enlarged thyroid caused mechanical bronchial irritation, the physician was successful in removing the condition by the reduction of the size of the goitre with this agent. It should be employed either in infusion or tincture, and the doses should be moderately large and long-continued. The infusion is prepared by taking $\frac{1}{2}$ ounce of the root to 1 gallon of water, and the patient is to drink freely of it. Or a saturated alcoholic tincture, or a saturated rye-whiskey tincture, may be given in $\frac{1}{2}$ -drachm doses 3 or 4 times daily. Its virtues are especially marked in the low stage of fevers. The dose is from 20 to 30 grains of the powdered root, given in water as warm as the patient can drink, and repeated every 1 or 2 hours, according to circumstances. The powder should always be kept in well-closed vials; it formerly constituted the "fever-powders" of some practitioners. Combined with extract of blue cohosh it forms an excellent agent in amenorrhœa and dysmenorrhœa; and is unsurpassed in after-pains, suppression of lochia, and the febrile symptoms which sometimes occur at the parturient period. In fevers it may be advantageously combined with specific leptandra, or resin of podophyllum, where it is found necessary to act upon the bowels or liver; and mixed with specific dioscorea, it will be found almost a specific in flatulent and bilious colic.

Specific Indications and Uses.—General prostration, malaise, hacking cough, loss of appetite, loss of weight, pleuritic pains, bronchial irritation, pyrexia.

Related Species.—As there was formerly some doubt as to the true plant which furnishes the crawley root, and, as Prof. King, in his first edition of the *American Dispensatory* (which he corrected, however, in a subsequent edition), described it as the *Pterospora Andromedea*, it may not be out of place to give a description of the latter. In many respects these plants resemble each other, as will be seen by the following description:

Pterospora Andromedea, Nuttall. *Albany beech-drops*, *Pine-drops*.—It belongs to the *Nat. Ord.*, *Ericaceæ*. It is a rare and singular plant, found on barren hills and shady uplands, and in a hard clay soil in the State of New York, and some of the northern states and Canada, flowering in July. It has a perennial, fleshy, tuberculous root, with many tubers which resemble the claws of a fowl. Stem or scape erect, simple, straight, dark-purple, cylindrical, covered with short viscid wool, from 8 to 30 inches in height, leafless, and sparsely beset with scales. Leaves none. Flowers pale or reddish-white, lateral, nodding, disposed in a terminal raceme from 6 to 12 inches long, composed of 50 or more flowers; pedicels irregularly scattered, from 8 to 8 lines in length, axillary to long, linear bracts. Calyx 5-parted; corolla roundish-ovoid, urn-shaped; limb 5-toothed, reflexed, inclosing the stamens. Stamens 10; filaments flat; anthers peltate, 2-celled, 2-awned, opening lengthwise; style short; stigma 5-lobed, capitate. Capsules or pod globose, depressed, 5-lobed, 5-celled, loculicidal. Seeds very numerous, minute, ovoid, tapering to each end, the apex expanded into a broad, reticulated wing, many

times larger than the nucleus (G.—W.). It was discovered near Albany, N. Y., in 1817, by Dr. Edwin James, who regarded it as a *Monotropa*, and as such, on authority of Dr. Torrey, was designated by Amos Eaton (*Man. of Bot.*, 2d ed.), under the name *Monotropa procera*.

CORDIALE RUBI FRUCTUS (N. F.)—BLACKBERRY CORDIAL.

Formulary number: 28.

Preparation.—"Blackberry juice, eighteen hundred and seventy-five cubic centimeters (1875 Cc.) [63 fl $\bar{3}$, 192 M]; cinnamon, in No. 40 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; cloves, in No. 40 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; nutmeg, in No. 40 powder, twenty-five grammes (25 Gm.) [386 grs.]; diluted alcohol (U. S. P.), a sufficient quantity; syrup (U. S. P.), eighteen hundred and seventy-five cubic centimeters (1875 Cc.) [63 fl $\bar{3}$, 192 M]. Percolate the powdered spices with diluted alcohol to obtain twelve hundred and fifty cubic centimeters (1250 Cc.) [42 fl $\bar{3}$, 128 M] of tincture, and add to this the blackberry juice. Then add thirty grammes (30 Gm.) [1 oz. av., 25 grs.] of purified talcum, set the mixture aside for 24 hours, occasionally shaking, and filter. Wash the filter with sufficient diluted alcohol to obtain thirty-one hundred and twenty-five cubic centimeters (3125 Cc.) [105 fl $\bar{3}$, 321 M] of filtrate; lastly add the syrup, and mix well"—(*Nat. Form.*).

Prof. Maisch used precipitated calcium carbonate instead of talcum, and suggests that as the syrup is apt to become turbid after standing, it should be filtered before dispensing, but in our opinion this should not be done. We have known blackberry cordial to become a gelatinous magma.

Action, Medical Uses, and Dosage.—This is a popular remedy for *diarrhœa*, and may be given in doses of $\frac{1}{4}$ to 1 fluid ounce.

CORIANDRUM (U. S. P.)—CORIANDER.

"The fruit of *Coriandrum sativum*, Linné"—(*U. S. P.*).

Nat. Ord.—Umbelliferae.

COMMON NAMES: *Coriander*, *Coriander fruit*.

Botanical Source.—Coriander is an annual, smooth herb, with a tapering root, and a round, erect stem, 12 or 18 inches high, more or less branched, leafy, round, and striated. The leaves are compound; the lower ones pinnate, on long, slender petioles, their leaflets wedge-shaped, or fan-shaped, acutely notched; upper leaves multifid, in fine, linear segments. The flowers are white, often with a reddish tint, disposed in compound, terminal, stalked umbels, of rarely more than 4 or 5 rays; the partial rays being more numerous. The calyx is 5-toothed, acute, unequal, and permanent. Petals obovate, emarginate, with inflexed lobes, the exterior radiating and bifid. The fruit is spherical, a line and a half in diameter, somewhat coriaceous, carminative, and aromatic. The seed is excavated in front and has a loose skin (L.).

History.—Coriander is an Italian plant, but introduced in all the warmer portions of Europe and temperate parts of Asia, flowering from May to July, and maturing its fruit early in the latter part of summer. Occasionally it is found in cultivation in the United States and South American States. When the fresh plant is bruised, it emits a disagreeable, bedbug-like odor, but by desiccation the fruit acquires its peculiar aromatic odor. The pleasant flavor is owing to a volatile oil, which may be procured by distillation. Alcohol takes up the active properties of the seed, water only partially.

Description.—"Globular; about 4 Mm. ($\frac{1}{4}$ inch) in diameter; crowned with the calyx-teeth and stylopod; brownish-yellow, with slight, longitudinal ridges; the two mericarps cohering, enclosing a lenticular cavity, and each furnished on the face with two oil-tubes; odor and taste agreeably aromatic"—(*U. S. P.*).

Chemical Composition.—The fruit contains a volatile oil, its chief constituent (see *Oleum Coriandri*), tannin, malic acid, mucilage, and a large quantity (about 13 per cent) of fatty material. The amount of ash was found to be 5.21 per cent (*Amer. Jour. Pharm.*, 1887, p. 28).

Action, Medical Uses, and Dosage.—Coriander is a stimulant and carminative, and is employed in medicine as an adjuvant or corrigent. Its dose is from 20 to 60 grains.

CORIARIA.—CURRIER'S SUMACH.

The leaves of *Coriaria myrtifolia*, Linné (*Rhus Coriaria*, Linné).

Nat. Ord.—Coriariaceæ.

COMMON NAMES: *Myrtle-leaved coriaria*, *Currier's sumach*.

Botanical Source.—This is a low, unarmed shrub of the Mediterranean regions. The leaves are opposite, entire, lanceolate, acute, short petiolate, and prominently 3-veined. The flowers are small, inconspicuous, in erect, terminal racemes. The sepals are 5, and imbricated in the bud. Petals 5, fleshy, gland-like and shorter than the calyx. The carpels are 5, distinct, and each is furnished with a long, thick, exerted stigma, which protrudes from the bud, and forms the most conspicuous part of the flower. The fruit is a small, black berry, not larger than a common pea.

History.—This shrub grows in Mediterranean Europe and Asia, and has been cultivated in gardens for ornamentation and for the leaves, which yield a black dye. The leaves have likewise been employed to adulterate senna—a dangerous fraud, as, according to Dr. Masters, they have caused convulsions and subsequent coma. The most distinctive characteristic is to be found in the three prominent veins of the leaves, whereas senna leaves have but one. The fruit of this shrub is poisonous, having proved fatal to French soldiers at Catalonia, who ate of it.

Description.—Coriaria leaves are from 1 to 1½ inches in length, smooth, entire, ovate-lanceolate, of a shiny bluish-green above, paler beneath, marked by a prominent mid-rib and two lateral nerves running near the border of the leaf nearly to the apex. They have an acrid, bitter, and very astringent taste.

Chemical Composition.—The leaves contain a poisonous bitter principle, investigated by Riban (1865), and named *coriamyrtin* ($C_{20}H_{20}O_{11}$). It is obtained by precipitating the aqueous extract of the leaves with subacetate of lead; filtering, treating the filtrate with sulphide of hydrogen; filtering again, and evaporating the filtrate to a syrupy consistence, from which substance ether dissolves the coriamyrtin; it may subsequently be purified by recrystallization from alcohol. It is a neutral, white body, very bitter, forming in from 4 to 6-sided prisms, which are soluble in 70 parts of cold and slightly more soluble in boiling water; are very soluble in boiling and in 50 parts of cold alcohol, also soluble in ether, chloroform, and benzol, but only slightly so in carbon disulphide. Dilute acids split it into a substance resembling sugar, and a resin (Husemann and Hilger, *Pflanzenstoffe*, 1884). In addition to this principle, the leaves contain tannin and are used for tanning leather and dyeing black. For microscopical tests for coriamyrtin, see T. F. Hanausek, *Amer. Jour. Pharm.*, 1893, p. 135.

Action, Medical Uses, and Dosage.—Both the leaves and berries are poisonous. M. Riban gave about 3 grains of the bitter principle to a large dog, and, although it was immediately ejected, horrible convulsions occurred in about 20 minutes, followed by death in 75 minutes; 1 grain of coriamyrtin killed rabbits, and the subcutaneous injection of $\frac{1}{2}$ of a grain killed a rabbit in 25 minutes. The symptoms following its administration to these animals were rapid succussions of the head extending to all the limbs, clonic and tetanic convulsions coming on in paroxysms; contractions of the pupils, trismus, and foaming at the mouth; the animals died from asphyxia and nervous exhaustion. Autopsy revealed vessels gorged with brown blood, coagulated in the cardiac cavities, the pulmonary artery, and the inferior vena cava; brown patches on the lungs; injection of the meninges; rapid cadaveric rigidity. No irritating action appeared upon the digestive tube. In cases where children have accidentally eaten the fruit, the symptoms have been a condition like that occasioned by alcohol (drunkenness), aphasia, frothing, purplish countenance, nausea, vomiting, convulsions, and death in from 15 to 20 hours. The plant has not yet been employed in medicine. The New Zealanders have a *wool-poison*, which is very destructive to human and animal life, and which, it is stated, is procured from *Coriaria sarmentosa*, Forster. *Coriaria ruscifolia* is also reputed poisonous.

CORNU CERVINÆ USTUM.—BURNED DEER'S HORN.

Preparation.—Take the horns of the deer (*Cervus virginianus*) any time from the month of August to December, or from the time they are in velvet (until just before they fall off), and when dry rasp them to a coarse powder. Place this in an iron vessel, cover it tightly, and put it in an oven, or other situation, where a strong heat can be gradually and increasingly applied. When the whole becomes of a light-brown color, like roasted coffee, and is readily pulverizable, cool, pulverize it, and keep it in well-stoppered bottles. During the application of the heat, which should be gradual, the powder should be occasionally agitated. The powder, thus prepared, is of a light chocolate, or brown color, of a peculiar, slightly aromatic, animal charcoal odor, and a very faintly astringent taste. During the operation disagreeable fumes are evolved.

Action, Medical Uses, and Dosage.—A powerful styptic. Especially an American remedy, of much value in *uterine hemorrhage* and *menorrhagia*. Has also been found beneficial in *dysentery*, *hemoptysis*, and other *hemorrhages*. Dose of the powder, 1 drachm, every $\frac{1}{2}$ hour, until the hemorrhage ceases permanently, which is usually from the first to the third or fourth dose; or 1 drachm of the powder may be placed in a gill of hot water, and a tablespoonful of the infusion be given every 5 or 10 minutes. It is often given combined with the compound powder of ipecacuanha and opium, or with other agents, as capsicum and opium, etc.

CORNUS.—DOGWOOD.

The bark and bark of the root of *Cornus florida*, Linné
Nat. Ord.—Cornaceæ.

COMMON NAMES: *Dogwood*, *Flowering dogwood*, *Flowering cornel*, *Boxwood*.

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 136; Johnson, *Med. Bot. of N. A.*, Pl. 5.

Botanical Source.—Dogwood is a small, indigenous tree, from 12 to 30 feet high, with a very hard and compact wood, covered with a rough, brownish bark,

Cornus florida.

much broken. It is a tree of tardy growth. The branches are opposite, spreading, smooth, and covered with a reddish bark, marked with rings at the place of the former leaves. The leaves are opposite, but partially expanded at the flowering time, ovate, acute, entire, petiolate, nearly smooth, dark-green and grooved above, and paler beneath, and marked with strong parallel veins. The flowers very small, of a greenish-yellow color, in heads or sessile umbels, upon peduncles an inch or more in length, surrounded by a large involucre, constituting the chief beauty of the tree when in flower. The involucre is composed of 4 white, nerved, obovate leaves, having their point turned abruptly down or up, so as to give them an obcordate appearance. The calyx is superior and campanulate, with 4 obtuse, spreading teeth. The corolla is composed of 4 oblong, ob-

tuse, reflexed petals. Stamens 4, erect; anthers oblong, with filaments inserted in their middle. Style shorter than the stamens, erect, bearing an obtuse stigma. The fruit is an oval drupe of a glossy scarlet color, containing a nut, or nucleus, with 2 cells and 2 seeds (L.—W.).

History.—*Cornus florida* grows in various parts of the United States, but more abundantly in the middle states. It flowers in April and May, sometimes earlier and sometimes later than this, depending upon the climate. The fruit

natures in autumn. This is one of the most conspicuous and handsome of our native trees when in bloom, and is frequently cultivated for its singular beauty. Its leaves turn red in the autumn. The wood is very compact and hard, and capable of receiving a high polish, and may be employed for many purposes. The American Indians extracted from the twigs and roots of this and other species a scarlet coloring matter for dyeing purposes. Dogwood bark was used considerably during the American Revolution as a substitute for Peruvian bark.

Description.—The bark of the stem, branches, and roots, is the medicinal part. That from the root is the best. It is found in commerce in broken fragments, somewhat quilled, $\frac{1}{4}$ or $\frac{1}{2}$ of an inch in thickness, ash-colored, with a reddish tinge, very friable, and very readily reduced to a powder of a similar color; it has but little odor, and its taste is astringent and feebly aromatic. Its properties are taken up by water or alcohol.

Chemical Composition.—Geiger, in 1836, obtained from the bark of the root a bitter principle (*cornine*), in pure form, and he proved that Carpenter's cornine is a mixture of calcium salts and the bitter *cornine* discovered by himself. Geiger's process is essentially as follows: Make a cold aqueous extract of the root-bark, shake with freshly prepared hydroxide of lead, filter, evaporate to dryness, abstract with absolute alcohol, filter again, add ether to turbidity, filter, and allow to evaporate spontaneously. *Cornine* crystallizes in silky needles, is soluble in water and alcohol, but sparingly soluble in ether. Its aqueous solution is precipitated by basic, but not by neutral, acetate of lead; also by silver nitrate. Fannic acid, mercuric, ferric, and barium chlorides are without effect upon it (Husemann and Hilger, 1884). Prof. Maisch, in 1859, showed that cornine is liable to be decomposed by exposure to heat or the atmosphere. The bark was found by H. K. Bowman (1869) and Chas. F. Kramer (1882) to contain 3 per cent of tannin (*Amer. Jour. Pharm.*).

Action, Medical Uses, and Dosage.—Dogwood bark is tonic, astringent, and slightly stimulant. It forms an excellent substitute for Peruvian bark, having frequently proved efficient in *periodic attacks* when the foreign drug failed. It may be used in many cases where quinine is indicated and can not be administered, owing to idiosyncrasy, etc. It may be used with advantage in cases where tonics are required, in *periodical fevers*, *typhoid fevers*, etc. Its internal employment increases the strength and frequency of the pulse, and elevates the temperature of the body. It should be used in the dried state, as the recent bark is apt to derange the stomach, and cause more or less pain in the abdomen, but which may be removed by 10 or 15 drops of laudanum. It is useful in *headaches* from quinine, in *general exhaustion* and *pyrosis*. An extract of the bark prepared by boiling it in water, and evaporating to the proper consistence, will be found one of the best forms in which to administer it. Dose of the powdered bark, from 20 to 60 grains, as often as required; of the extract, from 5 to 10 grains. The ripe berries formed into a tincture with brandy or whiskey, are a popular bitters among some country people; the flowers are occasionally used in the place of chamomile. Specific cornus, 1 to 20 drops.

Specific Indications and Uses.—"Tonic and antiperiodic; intermittent or miasmatic fevers; pyrosis; headache from quinine; general exhaustion" (Scudler); feeble, relaxed tissues; pulse feeble and temperature subnormal; quinism.

Related Species.—*Cornus sericea*, Linné. Swamp dogwood, Kinnikinnik, Rose-willow, Red-wier, Silky cornel, Red-willow. This is a shrub from 6 to 10 feet high. Stems several, erect, with a dark-red or purplish bark, and opposite, spreading branches, with downy twigs. Leaves opposite, from 2 to 4 inches long, half as wide, ovate, acuminate, varying from ovate and oval to lanceolate, nearly smooth above, with rather prominent veins, with a brown, silky down underneath, on petioles, from half an inch to an inch long. Flowers yellowish-white, small, disposed in large, terminal, depressed and woolly cymes or corymbs. Berries globose, bright-blue; stone compressed (L.—W.). Swamp dogwood is found in moist woods, and on the margins of rivers, from Canada to Carolina, flowering in June and July. The bark is the official part, that of the root being preferred. It resembles the bark of the following species (*C. circinata*) though it is not so warty and has a purplish tint. It possesses properties similar to those of *Cornus florida*, being, however, more astringent and less bitter. It has been found useful in *dyspepsia* and *diarrhœa*, and, in the same doses, may be employed as a substitute for the *C. florida*, and administered in a similar manner. An infusion is valuable in checking vomiting, especially that common to pregnancy and disease of the uterus. It has also been highly recommended in *dropsy*, *ulcers*, *malignant fevers*, and as an antiseptic.

Cornus circinata, L'Heritier. *Round-leaved dogwood*, *Broad-leaved dogwood*, *Alder-leaved dogwood*, *Round-leaved cornel*.—A shrub growing from 8 to 10 feet high, with straight, slender, greenish and verrucose branches. Leaves large, about as broad as long, orbicular, or very broadly oval, opposite, acuminate, waved on their edges, somewhat rough above, downy beneath. Flowers white, in small, spreading, depressed cymes, without an involucre. Fruit, or berries, a bright-blue, becoming lighter colored as they ripen, small, soft, hollowed at base, and crowned with the persistent style (W.—G.). This plant is found in North America from Canada to the Carolinas, and west to Missouri, growing on river banks, covees, and elevated ridges, and flowering from May to August. The dried bark is usually greenish or grayish-white and warty when from young twigs, brown-gray from old branches, with shining-brown confluent verrucose, short, cylindrical, or semi-cylindrical pieces, having a slight odor, and a somewhat aromatic, astringent, and bitterish taste. It imparts its virtues to water, and, in chemical character, has thus far been found similar to *Cornus florida* (R. Gibson, 1880). An astringent tonic, which may be employed in all cases where such agents are indicated. An infusion of it may be made by infusing an ounce of the coarsely-powdered bark in a pint of boiling water, and may be given in doses of 1 or 2 fluid ounces, several times a day. It is useful in *diarrhœa* and *dysentery*, and also as a gargle in *sore throat*. One ounce of the bark affords 150 grains of an astringent, intensely bitter extract, which may be used with benefit. The medicinal virtues of the plant, as well as its doses, are similar to those of *Cornus florida*.

Specific Indications and Uses.—Bitter taste, aversion to food, continual nausea, indigestion. Tincture (℥viii to dilute alcohol Oj) 20 to 60 drops, 3 times a day.

CORYDALIS.—TURKEY-CORN.

The tubers of *Dicentra Canadensis*, De Candolle (*Bicuculla Canadensis* (Goldie), Millspaugh; *Corydalis formosa*, Pursh; *Corydalis Canadensis*, Goldie).

Nat. Ord.—Fumariaceæ.

COMMON NAMES: Turkey-corn, Squirrel-corn, Wild turkey-pea, Stagger-weed.

Botanical Source.—This is an indigenous perennial plant, from 6 to 12 inches in height, and having a root-stalk bearing many small deep-yellow round tubers, about as large as peas. The leaves are ternately compound, with stalked divisions, incisely dissected into linear or oblanceolate segments, and decidedly glaucous underneath. The scape is slender and naked, rises from 8 to 12 inches in height, and bears a simple raceme of from 4 to 8 flowers, which are cordate-ovate, 5 lines broad at base and 7 to 9 lines long, short-petioled, nodding, greenish-white tinged with purple, and somewhat fragrant. The spurs or nectaries are short and rounded. The fruit is a many-seeded pod-like capsule.

History.—This beautiful little plant has been considerably employed in medicine. It flowers very early in the spring, in this section of the country as early as March; and the root or tuber, which is a small, round ball, should be collected only while the plant is in flower. It grows in rich soil, on hills and mountains, among rocks and old decayed timber, and is found westward and south of New York to North Carolina. It must be distinguished from the *Dicentra* (*Corydalis*) *Cucullaria*, which flowers at the same time, and very much resembles it.

Description.—The root or tuber of the *Dicentra Canadensis* (*C. formosa*, Pursh) when fresh is of a darkish-yellow color throughout, while the *Dicentra Cucullaria* (*C. Cucullaria*), or *White ear-drop* has a black cortex or rind, and is white internally. When dried, the external covering of the tuber is of a light grayish-yellow color, about $\frac{1}{4}$ of a line thick, inclosing an internal light-yellow substance; frequently it is of a dark color externally, and internally yellow or brownish-yellow. It has a faint peculiar odor, and a taste at first slightly bitter, succeeded by a somewhat, penetrating, peculiar, and persistent sensation, which gently influences the fauces, and increases the flow of saliva. Water or alcohol extracts its virtues.

Chemical Composition.—The only analysis we find on record of this species of *Corydalis* (*C. formosa*, Pursh), is that of Mr. William T. Wenzell (*Amer. Jour. Pharm.*, 1855, Vol. 27, p. 207), who found the root to contain *corydaline*, fumaric acid, yellow bitter extractive, acrid resin soluble in alcohol or ether, containing volatile oil, tasteless resin, soluble in alcohol and insoluble in ether, brown coloring matter, starch, albumen, bassorin, cellulose and cortical substance, and inorganic salts. The alkaloid *corydaline* occurs in several species of *Corydalis*, and was discovered in 1826, by Wackenroder, in the root of *Corydalis cava*, Schwgg. (*C. tuberosa*, De Candolle). It crystallizes in white prisms or fine needles, which melt at 135° C. (275° F.). It is odorless and tasteless in substance, but its alcoholic solution or the solutions of its salts are bitter. It is not soluble in water, soluble with

difficulty in alcohol, soluble in ether, chloroform, amyl alcohol, carbon disulphide, benzol, and turpentine. Its solution in alcohol has a strongly alkaline reaction. The formula for *corydaline* has been variously stated by different authors as $C_{16}H_{11}NO_4$ (Wicke), and $C_{17}H_{13}NO_4$ (Dobbie and Lauder, *Jour. Chem. Soc.*, 1892). Adermann's *corydaline* (*Amer. Jour. Pharm.*, 1890, p. 396) ($C_{17}H_{13}NO_4$), is probably not identical with the body long known by that name. The alkaloids of *Corydalis cava* have been investigated more closely than the others. E. Merck (*Archiv. der Pharm.*, 1893, p. 131), reports the occurrence of the following: *Bulbocapnine*, crystallizable, was present in largest quantity; fuses at $199^{\circ}C$. ($390.2^{\circ}F$.); *corydine*, an amorphous alkaloid; *corydaline*, the alkaloid of Dobbie and Lauder, fusing at $135^{\circ}C$. ($275^{\circ}F$.), and a base melting at $218^{\circ}C$. ($424^{\circ}F$.). The last alkaloid is probably not identical with Freund and Josephy's *corycavine*, isolated in 1893, together with *bulbocapnine*, from commercial *corydaline*. For Adermann's investigations, see *Amer. Jour. Pharm.*, 1890, p. 396. The preparation sold under the name CORYDALIN, as an old Eclectic concentration, is a mixture of *corydalis* constituents. It has a dark yellowish-brown color, and not being a definite, proximate principle, should not be confused with the alkaloids.

Action, Medical Uses, and Dosage.—This agent is peculiar to Eclectic practitioners, and was formerly much employed by them. It is tonic, diuretic, and alterative. In all *syphilitic affections*, it is an excellent tonic and alterative; and will likewise be found valuable in *scrofula*, and in many cases where tonics are indicated. As a tonic, it possesses properties similar to gentian, calumba, or other pure bitters; its alterative properties, however, render it of much value. In *syphilis*, especially in the constitutional form, when occurring in debilitated or broken-down constitutions, its efficacy is not equaled by any other agent as an alterative tonic; but from considerable experience with it, I am by no means satisfied that it exerts any real influence as an antisiphilitic, properly so-called, as has been heretofore believed (King). On the other hand, Webster and others regard it as a very valuable remedy in the disorders depending upon syphilis and *scrofula*, in the former comparing its action to that of *Berberis aquifolium*. It is claimed to be a remedy for *syphilitic nodes*, and particularly when they are recent. The tibia and the skull bones seem to be chiefly impressed by it. The *periosteal shin pains* of syphilis are said to be promptly alleviated by *corydalis*. In *syphilitic ulcerations* the drug should be given internally, and an infusion used locally. Prof. Locke recommends it in *amenorrhœa*, *dysmenorrhœa*, and *leucorrhœa* in atonic cases with a scrofulous or syphilitic diathesis. Also as a tonic to the digestive organs with enlargement of the abdomen due to atony, and declares it excellent in *dysentery* and *diarrhœa* with coated tongue, fetid breath, and poor digestion. It is likewise of value in the cachexia following *miasmatic fevers*. Dose of the infusion, from 1 to 4 fluid ounces 3 or 4 times a day; of the saturated tincture, from $\frac{1}{2}$ to 2 fluid drachms; of *corydalin*, from $\frac{1}{2}$ to 1 grain 3 or 4 times a day. The infusion to be made of 4 drachms of the powdered bulb and 1 pint of boiling water. Specific *corydalis*, 10 to 60 drops. Webster expresses the hope that the Eclectics will not let the homeopaths discover this remedy anew.

Specific Indications and Uses.—Syphilitic or scrofulous diathesis; yellow skin with lymphatic enlargements; syphilitic nodes. Increases waste and improves nutrition.

COTO.—COTO BARK.

The bark of an undetermined South American tree.

History.—Coto bark is exported from the interior of Bolivia, but the tree from which it is derived is unknown. (The bark of *Palicourea densiflora*, Martius, is known in Brazil under the name *Coto-coto*). In 1875, Dr. Wittstein received a few pounds for chemical examination, with the statement that it was produced by a species of *Cinchona*; this was disproved, however, by Harz, after a microscopic examination. In this country, coto bark and not *Para-coto bark* (see below), in substance, in tincture, or in fluid extract, is always used in medicine.

Description.—Coto bark reaches us in pieces of from 4 to 12 inches in length, 2 to 4 inches in width, and from $\frac{1}{4}$ to $\frac{3}{4}$ inch in thickness; the outer or corky portion is about $\frac{1}{8}$ of an inch in thickness, dark-brown internally, rusty upon

the inner surface, and externally grayish-brown or blotched with spots of white. The surface is somewhat rough. Beneath the thin cork it is of a dark-cinnamon color; fibrous upon its inner surface and intermixed with some granular matter; but, toward the outer part the granular matter increases in proportion until the reverse is true. Its fracture presents very numerous points of a golden yellow. The odor of the bark is aromatic, especially when freshly broken, reminding one of mace or of a mixture of mace and cinnamon. The taste is intermediate between that of mace and allspice, finally becoming acrid and biting. The dust is irritating when inhaled.

Chemical Composition.—Dr. Wittstein found this bark to contain a pale-yellow, aromatic, volatile oil, of less density than water, and biting to the taste; a volatile alkaloid resembling propylamin, and two resins, besides a tannin, starch, formic, butyric, and acetic acids, etc. In 1876, Jobst obtained a crystallizable body, *cotoin*, possessing the biting taste peculiar to the bark, and which he supposed represented its medicinal virtues. Cotoin was obtained by exhausting the powdered bark with cold ether, distilling the greater part of the solvent, treating with light petroleum benzin, 6 parts (which caused the precipitation of a copious amount of resin), and evaporating the benzin solution to the point of crystallization. Afterward, by the same process of isolation, he found another crystalline, but non-pungent body in another sample of bark (since named *Paracoto bark*), and named it *paracotoin*. Still further examinations by Jobst and Hesse gave conflicting results, and later researches by the same chemists demonstrated that the discrepancies were due to the fact that two barks were upon the market under the name *coto*, and that only to the first, that examined by Wittstein, should the term (*coto*) be applied; *PARA-COTO BARK* being accepted as the name of the second (see *Related Drug*).

Coto bark, according to the investigations of Jobst and Hesse (*Lieb. Annal.*, Vol. 199, 1879, pp. 17-96; also see *Amer. Jour. Pharm.*, 1880, pp. 20-28), contains *cotoin* and *dicotoin*, the latter occurring in the mother liquors from the preparation of *cotoin*, and being regarded as its anhydride. Cotoin forms square prisms of a light yellowish-white color, having an intensely biting taste, and melting at 130° C. (266° F.). The dust of *cotoin* causes violent sneezing and coughing. It is soluble in alcohol, ether, acetone, chloroform, carbon disulphide, and boiling water, and nearly insoluble in cold water. It is soluble in alkalies and alkaline carbonates, being again precipitated by mineral acids, and even carbonic acid gas. Its aqueous solution reduces gold and silver salts in the cold, and exhibits some characteristic color reactions with nitric and sulphuric acids, ferric chloride, etc. Its formula is $C_{22}H_{30}O_6$, and tribromine- and triacetyl substitution products were obtained by the authors.

Action, Medical Uses, and Dosage.—Coto bark, in the form of powder, tincture, or extract, has been successfully employed in *diarrhœa*; M. von Gietl considered it a specific in the several forms of *diarrhœa*. Burkhart and Rieker have found it to possess extraordinary virtues in *intestinal catarrh*, *diarrhœa*, and *dysentery*. Good results are obtained from it in some cases of *cholera infantum*, and strong endorsement has been accorded it as a remedy to control the *colliquative sweats of phthisis*. It has likewise been employed beneficially in *colic*, *dental nervous pains*, in *gout*, and in *rheumatism*. The tincture made by percolating 1 part of the coarsely powdered bark with 9 parts of alcohol, may be given in doses of 10 drops, repeated every 2 hours; the powder, in doses of $\frac{1}{2}$ grain, repeated 4, 5, or 6 times a day. The effects of the tincture and the powder are, however, very disagreeable, owing to the essential oil and the resinous principles present in them, producing a persistent, burning taste in the mouth, with increased flow of saliva, a burning sensation in the stomach, with eructations and vomiting, on which account the active principle, *cotoin*, has been substituted, as it does not occasion these unpleasant symptoms, and is fully as efficient. Cotoin is especially useful in cases in which opium and its preparations are contraindicated; its dose is very small, thus: In 4 fluid ounces of distilled water dissolve $\frac{1}{10}$ of a grain, or 1 $\frac{1}{2}$ grains of *cotoin*, and to this add 10 drops of alcohol and 1 ounce of syrup. The dose is a tablespoonful every 1 or 2 hours.

Related Drug.—*PARA-COTO BARK*. Para-coto bark resembles coto bark in its general appearance, but has a much weaker odor, and only a faintly pungent, acrid taste. It reaches

market under the name *Coto*, and is packed in exactly the same manner, thus, it is said, rendering its substitution in commerce frequent. The principal constituents are, *paracotoin*, which crystallizes from an ethereal tincture of para-coto bark, in yellowish scales, and has the composition $C_{27}H_{32}O_8$. Solution of hydrate of potassium, or of sodium converts it into *para-cotoic acid* ($C_{27}H_{30}O_8$). *Leucotin*, a substance crystallizing in white prisms, is present in larger proportion, and is obtained by agitating the crystalline mass resulting from evaporation of the tincture of para-coto bark with glacial acetic acid. The leucotin dissolves in the acetic acid, and may be purified by recrystallization from hot diluted alcohol. Its composition is $C_{24}H_{28}O_{10}$. *Ozyleucotin* is obtained from the alcoholic mother liquor, after separation of paracotoin, and has the composition, $C_{24}H_{28}O_{10}$. An agreeable volatile oil was also obtained by distillation of the bark with superheated steam, colorless, specific gravity 0.9275, and separable into 5 distinct compounds by means of fractional distillation, with boiling points ranging from $160^{\circ} C.$ ($320^{\circ} F.$) to $242^{\circ} C.$ ($467.6^{\circ} F.$). In addition to the foregoing, several other products were identified, *e. g.*, *dibenzoyl hydrocotoin* ($C_{28}H_{32}O_8$), *hydrocotoin* ($C_{12}H_{14}O_4$), and *piperonylic acid* ($C_8H_8O_4$), and we refer the reader, if interested, to the original article, or the abstracts published in the *Amer. Jour. Pharm.*, and in *New Remedies*, January, 1880 (see under *Coto Bark*; also see Ciamician and Silber, *Chem. Centralbl.*, 1892, Vol. I, p. 751).

OOTULA.—MAY-WEED.

The whole herb *Maruta Cotula*, De Candolle (*Anthemis Cotula*, Linné; *Maruta fetida*, Cassini).

Nat. Ord.—Compositæ.

COMMON NAMES: *May-weed*, *Wild chamomile*, *Dog fennel*, *Dog chamomile*.

Botanical Source.—*Maruta Cotula* has an annual, twisted, tapering, fibrous root, with one or more stems, erect, branched, bushy, leafy, angular, furrowed, nearly smooth, and solid, from 1 to 2 feet high. Its branches are corymbose. The leaves are alternate, sessile, bright-green, smooth, or slightly hairy, bipinnatifid, and cut. The segments are narrow, flat, a little succulent, spreading, rather distant, not crowded or parallel, and somewhat bristle-pointed. The flower-heads are solitary, on terminal, striated, slightly downy peduncles. The involucre is more or less hairy, its scales almost equal, obtuse, and slightly bordered. The disk is convex, lemon-colored, with the slender, bristle-shaped, or subulate, greenish scales not quite so tall as the opening florets. The rays are white, elliptical, 3-toothed, deflexed, and close to the stalk, at night. The receptacle is highly conical, almost cylindrical, and beset with slender, permanent scales. The seeds are brown, obovate, furrowed, and sometimes rough, with minute tubercles (L.).

History.—May-weed is indigenous to Europe, and is common in this country, where it is known as *Wild chamomile*, *Dog fennel*, etc. It may be found growing in waste places, in hard, dry soils, especially along roadsides. Its flowers are white, and appear from June until September. Every part of the plant is acrid and fetid, and, according to Linnæus, is grateful to toads, and is annoying to fleas and flies. The whole plant is medicinal. Its taste is bitter and pungent; water or alcohol extract its properties.

Chemical Composition.—Mr. W. H. Warner found it to contain oxalic, valeric, and tannic acids, coloring matter, albumen, acrid oleoresin, insoluble bitter extractive, volatile oil, and various salts (*Amer. Jour. Pharm.*, Vol. XXX, p. 390). From an analysis, in 1859, Patone announced an alkaloid under the name *anthemidine*, and a crystallizable acid, of a bitter taste, and soluble in ether and alcohol, to which the name *anthemidic acid* was given.

Action, Medical Uses, and Dosage.—Tonic, emetic, antispasmodic, emmenagogue and epispastic. The cold infusion or extract may be substituted, as a tonic and antispasmodic, in all cases, for the foreign article. The extract may be used in *sick headache*, and in convalescence from *fevers*. A warm infusion may be

used as an emetic or diaphoretic. It has been efficient in *amenorrhœa*. The fresh plant bruised and applied to the skin, will cause vesication, and the sores heal readily. A powerful epispastic is made by preparing the fresh leaves of *M. Cotula* and *Polygonum punctatum*, equal parts, and moistening them with a small quantity of spirits of turpentine. Dose of the infusion, from 1 to 4 fluid ounces, as often as required.

COTYLEDON.—NAVELWORT.

The plant *Cotyledon Umbilicus*, Linné (*Umbilicus pendulinus*, De Candolle).

Nat. Ord.—Crassulacæ.

COMMON NAMES: Pennywort, Navelwort, Cotylet.

Botanical Source.—A succulent, herbaceous perennial, having an erect stem about 6 inches in height, arising from a tuberous, fleshy root. The leaves are small, peltate, concave, fleshy, and somewhat rounded, with a repand-crenate border, the upper leaves being smallest. The flower-stem bears a profusion of small pale or greenish-yellow, and bell-shaped, pendulous, tubular flowers arranged in a spike.

History and Chemical Composition.—This succulent perennial is indigenous to England and south and west Europe. It inhabits old rocks, stony ruins, and sandy situations, growing on dry banks. When dried, the plant is odorless, and possessed of a mucilaginous taste. If the plant be powdered and exposed to the air, it acquires a peculiar, fish-like odor, probably due to *trimethylamine*, which it has been found to contain. It also contains an ammonium salt, potassium nitrate, salts of potassium, sodium, calcium, oxide of iron, mucilage, cellulose, tannin, yellow coloring principle, chlorophyll, a volatile oil, and 95 per cent of water (fresh plant).

Action, Medical Uses, and Dosage.—This plant was formerly bruised and applied to *contused wounds*. At one time it acquired a reputation, in England, as a remedy for *epilepsy*, but, after an extended trial, was discarded as worthless. Its composition is such that possibly the plant is not wholly inert. The fresh juice may be administered in doses of from $\frac{1}{4}$ to 1 fluid ounce, 3 times a day.

CREOSOTUM (U. S. P.)—CREOSOTE.

"A mixture of phenols, chiefly guaiacol and creosol, obtained during the distillation of wood-tar, preferably of that derived from the beech, *Fagus sylvatica*, Linné (Nat. Ord.—Cupuliferæ)"—(U. S. P.).

SYNONYMS: *Creasotum*, *Creasote*.

History and Preparation.—Creosote was discovered by M. Reichenbach in 1830. It exists in impure pyroligneous acid, and in the tar obtained by the distillation of wood, the latter yielding it in the greatest quantity. As regards the spelling of the word *creosote* (the *British Pharmacopœia* prefers the spelling *creasote*), see Chas. Rice in *Amer. Jour. Pharm.*, 1894, and Jos. Ince, *Pharm. Jour.*, 1895, p. 305. Briefly *creosote* is prepared as follows (see Prof. S. P. Sadtler, *Indus. Org. Chem.*, 189):

The lower, tarry layer resulting from the destructive distillation of wood (see *Acidum Aceticum Pyrolignosum*) furnishes the material from which *creosote* is obtained. By distillation and rectification the tar is differentiated into an aqueous distillate containing wood spirit and pyroligneous acid, an oily distillate lighter than water, another distillate heavier than water, and the residual pitch. The *creosote* oils constitute the fraction of the heavier distillate collected between 150° and 250° C (302° and 482° F.). These oils are abstracted by means of solution of caustic soda, which separates the aqueous, *creosote*-bearing layer, from which the addition of sulphuric acid liberates the *creosote*. The oils are then further purified by distilling with steam, and finally rectifying in glass retorts. *Creosote* oils from wood-tar contain a little phenol (carbolic acid), which is more abundant in coal-tar *creosote*. *Creosote* contains the higher phenols and their methyl ethers, e. g., *guaiacol* ($C_6H_4[OCH_3].OH$), *creosol* ($C_6H_3[CH_3][OCH_3].OH$), *xylenol* (*phlorol*) ($C_6H_3[CH_3].OH$), *methyl-creosol*, etc. Max Pfeinger (*Archiv. der Pharm.*) examined a certain specimen of *birchwood creosote*, and found it to consist

of *guaiacol* and *creosol* in largest quantity, of *creosol* and *xylol* (the homologues of phenol), in smaller amount, while phenol (carbolic acid) could not be identified.

Description.—The official creosote is “an almost colorless, yellowish or pinkish, highly refractive, oily liquid, having a penetrating, smoky odor, and a burning, caustic taste; usually becoming darker in tint on exposure to light. Specific gravity, not below 1.070 at 15° C. (59° F.). Soluble in about 150 parts of water at 15° C. (59° F.), but without forming a perfectly clear solution. With 120 parts of hot water it forms a clear liquid which, on cooling becomes turbid from the separation of minute oily drops. The filtrate from this yields a reddish-brown precipitate with bromine T.S. (distinction from carbolic acid). Soluble, in all proportions, in absolute alcohol, ether, chloroform, benzin, carbon disulphide, acetic acid, and fixed and volatile oils. It begins to boil at about 205° C. (402.8° F.), and most of it distills over between 205° and 215° C. (401° and 419° F.). When it is cooled to -20° C. (-4° F.), it becomes gelatinous, but does not solidify (difference from carbolic acid). It is inflammable, burning with a luminous, smoky flame. Creosote is neutral or only faintly acid to litmus paper”—(*U.S.P.*). When concentrated it destroys the epidermis, dissolves iodine, phosphorus, sulphur, and black oxide of copper, reduces oxide of mercury at a boiling temperature, and dissolves the coloring matter of indigo, which is precipitated on the addition of alcohol and water. It also dissolves camphor and many of the resins. An aqueous solution preserves meat, which has been dipped into it. Concentrated nitric and sulphuric acids decompose it.

Tests.—Creosote from wood-tar is liable to be adulterated with crude carbolic acid, or it may even be totally substituted by it. F. B. Eisenhart (*Amer. Jour. Pharm.*, 1886, p. 593), showed that of 15 specimens analyzed, 8 were carbolic acid. In another instance (*Massachusetts Health Report*, see *Amer. Jour. Pharm.*, 1886, p. 111), the extent of substitution was approximately 60 per cent. Creosote is sometimes impure by reason of the presence of some of the other principles (indifferent oils) formed by the destructive distillation of wood. Since pure creosote is completely soluble in concentrated acetic acid and solution of caustic potash, while the above adulterations rise to the top of the solution, this treatment affords a ready means of separation. If creosote leaves a stain on paper not removable by heat, it contains a fixed oil.

Besides, the Pharmacopœia gives the following tests: “On mixing equal volumes of creosote and collodion in a dry test-tube, no coagulum should form. If 1 volume of creosote be mixed with 1 volume of glycerin, a nearly clear mixture will result from which the creosote will separate on the addition of 1 or more volumes of water. On adding to 10 Cc. of a saturated, aqueous solution of creosote 1 drop of ferric chloride T.S., the liquid will acquire a violet-blue tint which rapidly changes to greenish and brown, with formation, usually, of a brown precipitate. (The preceding 3 tests show difference from and absence of notable quantities of carbolic acid). On mixing 2 Cc. of creosote with 8 Cc. of a 7.5 per cent solution of sodium hydrate, a clear, pale yellowish liquid results, which becomes turbid when diluted with water, but clears up after 60 Cc. have been added (absence of neutral oils). If 1 Cc. of creosote be mixed with a warm, 20 per cent solution of potassium hydrate in absolute alcohol, a solid, crystalline mass will form upon cooling. If 1 Cc. of creosote be shaken with 2 Cc. of benzin and 2 Cc. of freshly prepared barium hydrate T.S., upon separating, the benzin should not be blue or muddy, and the aqueous layer should not have a red tint (absence of xerulignol and some other high-boiling constituents of wood-tar)”—(*U. S. P.*). For a valuable paper on the distinctive tests for carbolic acid, cresylic acid (cresol), and creosote, by Alfred H. Allen, see *Amer. Jour. Pharm.*, 1879, p. 28-36.

The above-mentioned ferric chloride test, while very sharp for carbolic acid alone (in the quantities above indicated, it yields, with coal-tar acids, a permanent violet-blue coloration), can not be used to identify carbolic acid when mixed with creosote. Flückiger's test is said to overcome this difficulty (*Amer. Jour. Pharm.*, 1892, p. 195). In principle it is as follows: 4 Cc. of creosote are mixed with 1 Cc. of ammonia water, the mixture heated to 60° C. (140° F.), spread in a flat-bottom dish to form a thin layer, and the vapors of bromine brought in contact with it. Pure creosote yields a brown color, turning green, while carbolic acid forms a deep blue. For the valuation of *guaiacol* in creosote consult the same reference.

Action, Medical Uses, and Dosage.—Creosote, when applied to the mucous tissues, or to the denuded cutis, occasions sharp, burning pain, and if the article be the commercial variety, which generally contains carbolic acid, it coagulates the albumen of the tissues and may cause ulceration of the part. The action of creosote closely resembles that of carbolic acid, and, in view of the fact that a large part of so-called creosote employed in medicine is carbolic acid, many of the effects attributed to the former are those previously described under the latter agent. Creosote may be absorbed when applied to ulcerations, so that poisonous effects may be experienced. Taken internally to excess, pain in the abdomen, with bloody discharges, may occur, and fatal cases show destructive lesions of the parts over which the creosote has passed. As high as 500 drops of creosote have been taken in 24 hours, which goes to prove that, when pure, its physiological effects must be different from those of carbolic acid, the action of which it has always been thought to resemble, and the range of application of the two agents have been considered very similar. Its antiseptic power is fully equal to, if not superior, to that of phenol. A thorough investigation of the action of creosote has not as yet been made. Anatomical specimens may be kept in an aqueous solution of creosote, equally as well as in alcohol. Moldiness in ink may be prevented by the addition of a few drops of creosote to it; it is also added to preservative fluids for microscopical preparations for the same purpose. Creosote protects wood against most of the attacking insects, as the marine teredo, and the land white ant; also from moisture, fungi, and animal and vegetable life, and prevents dry rot and other species of decay. Probably carbolic acid would answer a better purpose in these several instances. Commercial creosote (holding carbolic acid) forms a gelatinous compound with $\frac{1}{3}$ its weight of collodion; this is not the case with pure beech-tar creosote.

A poisonous dose of creosote occasions dimness of vision, fixation of the eyes, vertigo, diminution of the action of the heart, coma, and often convulsions. The treatment must be ammonia and stimulants to counteract the depression of the vital powers, the soluble sulphates with white of egg, oleaginous and mucilaginous drinks.

Creosote is irritant, styptic, antiseptic, narcotic, escharotic, and probably diuretic. Internally, in small doses, it is sedative and anæsthetic. It is used in *diabetes mellitus*, *epilepsy*, *hysteria*, *neuralgia*, *chronic catarrh*, *hemoptysis*, *hematemesis*, *chronic gonorrhœa* and *gleet*, and to arrest nausea or vomiting occasioned by *hysteria* or *pregnancy*, but further and more accurate investigations are required before we can positively determine its value in these affections when internally administered. Its value in vomiting is enhanced by its property of partially paralyzing the sensitive gastric nerve filaments, and, like carbolic acid, it is undoubtedly of marked value in *yeasty* or other *fermentation* of the contents of the stomach. As early as 1833, Reichenbach claimed creosote as a remedy for *phthisis*. Following him came Elliotson (1834), Carmack (1836), and others, who made similar claims, but the remedy failed to find favor and its use for this purpose was dropped, to be revived again by Imlay, in 1876, since which time its use in this country has amounted to "a fad" with certain practitioners. Imlay only employed it by spray. It is, however, again fast losing ground as a remedy for consumption, the relief in cases apparently benefited now being attributed largely to the use of restoratives employed with it and the hygienic precautions observed. Even those who made a large use of it, upon the ground that it would destroy the tubercle bacillus, now admit that it possesses no such power, and that it does not in any way benefit the consumptive patient. On the contrary, when long taken, the patient becomes possessed of a disgust for medicine and food, while gastrointestinal irritation is so far produced as to induce nausea, vomiting, and diarrhoea, with the consequent nervous depression resulting from such a state.

Externally, as more commonly used, it has been found efficient in *scaly cutaneous affections*, *burns*, *external wounds*, *capillary hemorrhage*, *indolent and gangrenous ulcers*, also *scrofulous*, *syphilitic* and *fistulous ulcers* and *scrofulous ophthalmia*; as a gargle, in *putrid sore throat*, as an injection, diluted with oil of almonds, in *chronic suppurations of the external meatus of the ear*, and it is one of the most effective applications in *toothache*, depending on exposure of the nerve. A saturated solution of camphor in creosote, applied by means of camel's hair pencil slightly moistened

with it, has been efficient in *gangrene of the mouth*. Creosote should most usually be sufficiently diluted, and used in the form of mixture, solution, or ointment. Dose, from 1 to 3 drops, diluted with 2 or 3 fluid ounces of weak aromatized mucilage, 3 or 4 times a day. When employed in phthisis it is generally given with cod-liver oil, wine and gentian, etc.

Creosote water (see *Aqua Creosoti*) has been used as a local application in various ways to stimulate *indolent ulcers* and *abscesses*, to neutralize bad odors, and to stimulate mucous tissues, as of the mouth and throat. Internally, from $\frac{1}{2}$ fluid drachm to 3 or 4 fluid drachms of aqua creosoti may be given for a dose. For inhalation, take 1 part of creosote to 3 of alcohol.

Related Bodies.—CREOSOTUM CARBONICUM. A transparent, yellowish-brown, honey-like body, without odor, and having a feebly bitter taste, has been introduced under this name as a remedy for *phthisis*. It is soluble in the fatty oils, but not in water. By the action of alkalis, and when within the system it undergoes decomposition into carbonic acid gas and creosote. As much as 75 grains have been given in a day (Chaumier, 1892).

CREOSOTAL is the name given to the carbonate of creosote, containing 90 per cent of pure creosote and rich in guaiacol. For its properties and uses, see *Amer. Jour. Pharm.*, 1894, p. 40.

CRETA PRÆPARATA (U. S. P.)—PREPARED CHALK.

FORMULA: CaCO_3 . MOLECULAR WEIGHT: 99.76.

SYNONYM: *Creta lœvigata*.

Source.—Chalk is an impure calcium carbonate, a substance that exists widely distributed over the globe, and constitutes a large share of the rock formations of the earth. It occurs in various modifications, *e. g.*, in the form of limestone, marble, calc-spar (Iceland spar), and aragonite. It is the basic substance in coral, and crustacean and mollusk shells. The bones and teeth of man and animals, and the solid portion of egg-shells, are composed chiefly of calcium carbonate. It is frequently found in pathological conditions of the human system, such as calcifications, and occasionally as renal calculi. The so-called *otoliths* in the internal ear of the human species are crystallized calcium carbonate. Chalk in quantities has not been found in the United States, but is obtained in abundance in the south of England, where it forms the immense chalk cliffs of the English channel, and along the adjacent coast of France. It occurs in the newest secondary strata, and constitutes, with its subordinate rocks, a distinct and peculiar formation. It is scarcely ever a perfectly pure calcium carbonate, always containing silica, alumina, iron, and fossil remains of land and marine animals, in great quantity, *e. g.*, the shells of Foraminifera of microscopic size. Chemically it is impure carbonate of calcium, and is identical with marble (which see) in its relations to water, air, alcohol, heat, and acids.

Chalk is termed by some writers *native friable carbonate of lime*. There are two kinds, *hard* and *soft chalk*; the latter is commonly preferred for medicinal purposes, though the former may be employed as well. It has an earthy appearance, white when pure, grayish-white or even reddish, when impure, inodorous, tasteless, opaque, insoluble, giving a sensation of roughness when touched, very friable, with an earthy fracture, leaving a white mark when drawn over a resisting surface, and having the specific gravity 2.3 to 2.7. Chalk is completely dissolved by hydrochloric acid, with the exception of the silica present; if this solution contains alumina, the addition of ammonia will cause a white precipitate; if it contains oxide of iron the precipitate will be in yellow-brown flakes.

Preparation.—Chalk should not be employed as a medicine until it has been divested of its gritty particles by levigation and elutriation, as follows: Rub chalk into a paste, with a little water. Stir this into a large quantity of water, and when the coarse particles have subsided, pour off the supernatant turbid liquor, and let it settle. Decant the water, and dry the powder upon some flat, porous body. Molded it forms, when dried, conoid or pyramidal figures, which are known as prepared chalk. *Whiting* is chalk freed from its silicious particles. A finer grade, soft and smooth, is known as *Paris* or *Spanish white*; this when mixed with pigments, forms the basis of *pastel pencils*.

Description.—CRETA PRÆPARATA (U. S. P.). "A white, amorphous powder, often molded into conical drops, odorless and tasteless; permanent in the air.

Almost insoluble in water; insoluble in alcohol. Soluble in diluted acetic, hydrochloric, or nitric acid with copious effervescence, but without leaving more than a trifling residue. When heated to redness, prepared chalk loses carbon dioxide and is converted into lime"—(U. S. P.).

Tests.—"The solution in diluted acetic acid yields, with ammonium oxalate T.S., a white precipitate insoluble in acetic, but soluble in hydrochloric acid. If from the solution in diluted acetic acid the calcium be completely removed by precipitation with ammonium oxalate T.S., in slight excess, the filtrate should not be rendered very turbid upon addition of sodium phosphate T.S. and a little ammonia water (limit of magnesium). Another portion of the solution in acetic acid should not assume more than a slight bluish tint upon addition of potassium ferrocyanide T.S. (limit of iron). Another portion of the same solution should not be rendered turbid by the addition of barium chloride T.S. (absence of phosphate). In another portion of the solution no precipitate should occur upon addition of potassium dichromate T.S. (absence of barium)"—(U. S. P.). Prepared chalk has been largely adulterated with, or entirely substituted by calcium sulphate (powdered gypsum). The latter is whiter than prepared chalk, and has a grayish cast. Gypsum does not effervesce when treated with acids; its substitution may thereby be at once recognized.

Action, Medical Uses, and Dosage.—Antacid, astringent, and absorbent. The animal cretaceous products probably act more kindly upon the stomach. Used in *acidity of the stomach* and *acid diarrhoea*, combined with aromatics and opium; externally to *ulcers* and *burns*, to absorb the *ichorous discharges*, and to prevent *excoriation* from pressure or friction. Dose, from 10 grains to 1 drachm.

Related Drugs.—**TESTA PRÆPARATA**, *Prepared oyster shell*. The prepared shell of *Ostrea edulis*, Linné. *Class*, Acepala; *Order*, Lamellibranchia; *Family*, Ostrea. This product but little used at the present time, was official in the U. S. P. of 1870. Its chief constituent is calcium carbonate, which is present to the extent of from 87 to 98 per cent, being contained in greater proportion in the internal pearly layer of the shell. Calcium phosphate, silica, and other earthy substances form the remainder of the inorganic material. The organic matter may amount to from 0.5 to nearly 5 per cent.

CALCAREA CARBONICA or *Calcareo Ostrearum* (Hering), is essentially the same as **TESTA PRÆPARATA**, and is a standard remedy among Homœopathists. The original process of preparation as pursued by Hahnemann, was to break clean, thick oyster shells into small pieces and after carefully selecting fragments of the inner, snow-white portion, to powder them. This was then used in making triturations. Prof. H. T. Webster is a strong advocate of the use of this remedy in *strumous conditions* with faulty action of the lymphatic glands. Lack of nutrition resulting in *rickets* and the *head sweating* of debilitated infants, are positive indications for it. *Mucorrhœa*, or copious muco-purulent discharges as in *bronchorrhœa*, and in the *post-nasal inflammations* and *chronic pharyngitis*, marked results are claimed by this author. He also employs it in *non-irritative vaginal* and *uterine leucorrhœa* due to relaxed tissues. In *asthenic* and *chronic coughs* it is adapted where there is but little inflammation or fever. Chronic cases are best treated with it. It is said to be a positive agent in some cases of *gout*. Webster employs the 3x trituration in doses of 1 to 3 grains 3 or 4 times a day. Scudder gives as the specific indications for *calcareo carbonica* enlargement of lymphatic glands; pallid, inelastic skin; softness of tissues; diseases of the reproductive apparatus in women, with these symptoms (*List of Spec. Ind.*).

OS SEPÏE, *Cuttlefish bone*.—The chalk-like bone found in the mantle of the *Sepia officinalis*, Linné. *Class*, Cephalopoda. Collected principally in the Mediterranean waters. This bone is white, calcareous, oval-oblong, convex on both surfaces, a portion of it being porous and broken, while the back part of the surface is hard, glossy, and smooth. Although containing minute quantities of calcium phosphate, the bone is chiefly made up of calcium carbonate (80 to 85 per cent); organic, gelatinous matter amounting to from 10 to 16 per cent is present. Cuttlefish bone is largely used to furnish calcium carbonate to cage-birds.

CORALLIUM.—*Coral*. The calcareous skeleton of *Corallium rubrum*, Lamarck (*Isis*); *Pallas* and Linné), and *Oculina virginica*, Lamarck. *Class*, Polypipera. Corals inhabit the bottom of some parts of the sea, and consist of branching skeletons, covered with pulpy tissues. These chalk-like skeletons were formerly employed in medicine for the same purposes as calcium carbonate, but are now chiefly collected as ornaments. The first species is a dull-red color, while the second is milky-white, the color of the former being due to iron oxide, which is present to the extent of nearly 5 per cent. The skeleton contains a small and small quantity of animal matter, a little magnesium carbonate, but is mostly composed of calcium carbonate. The Homœopaths use *corallium rubrum* in doses of 2 or 3 drops of a 6x dilution, 2 or 3 times a day, in *convulsive* and *nerveous coughs*, not originating in the pulmonary tissues. Webster claims good results from it in *whooping-cough*.

LAPIDES CANCERORUM, *Lapilli cancerorum*, *Calculi cancerorum*, *Oculi cancerorum*, *Crab's stones*.—Calcareous concretions found in the stomach of *Amacus furiatilis*, Fabricius (*Crustacea*), or *Crawfish*. These bodies are composed of about 64 per cent of calcium carbonate.

about 16 per cent of calcium phosphate, small amounts of other salts, and the remainder of animal matter. They are circular, plano-convex, and have a concentric furrow on their flat surface. They range from $\frac{1}{4}$ to $\frac{1}{2}$ inch in diameter, the cross section exhibiting a series of concentric layers. They effervesce in hydrochloric acid, in which they do not completely dissolve, thus being distinguished from spurious crab's eyes, which are wholly dissolved by that acid. In the presence of boiling water crab's eyes assume a pinkish-red hue.

CHELÆ CANCROBUM, Crab's claws.—Finely powdered crab's claws were formerly employed medicinally as an antacid and absorbent. They contain calcium carbonate, 60 parts; calcium phosphate, 14 parts; and of organic matter, 26 parts.

Other Calcium Compounds.—**CALCIUM BENZOAS** ($\text{Ca}[\text{C}_7\text{H}_5\text{O}_2]_2 \cdot 3\text{H}_2\text{O}$), *Calcium benzoate*. To a hot solution of benzoic acid add calcium carbonate in slight excess, filter, and evaporate to crystallization. Handsome radiating, tuft-like crystals, soluble in cold (1 in 18), and in boiling water (1 in 6). Used in 10-grain doses in *struma*, *incipient hepatic cirrhosis*, *scrofulous conditions*, and *uric acid diathesis*.

CALCIUM HIPPUKAS ($\text{Ca}[\text{C}_6\text{H}_7\text{NO}_3]_2 \cdot 3\text{H}_2\text{O}$), *Calcium hippurate*.—Prepare like the preceding, using hippuric acid in place of the salicylic acid. It resembles calcium benzoate.

CALCIUM HYPOSULPHIS ($\text{CaS}_2\text{O}_3 \cdot 6\text{H}_2\text{O}$), *Calcium hyposulphite*, *Calcium thio-sulphate*, *Calcium sulpho-sulphate*.—The hyposulphites closely resemble the sulphites in therapeutic action. They are more stable than the latter and easily dissolved by water. Upon adding an acid to their solutions, sulphur is precipitated. They are generally prepared by heating sulphur with a sulphite or bisulphite, in the presence of water. Hyposulphite of calcium may be prepared by boiling together lime (40), sulphur (400), and pure water (400), filtering, and then passing washed sulphur dioxide into the solution of calcium polysulphide formed until the former is decolorized. Carefully crystallize at a low heat, when 6-sided efflorescent crystals will form. A syrup may be prepared from 1 part of crystallized calcium hyposulphite, 2 parts of distilled water, and 17 parts of syrup of orange. Dose of syrup, 1 to 4 fluid drachms; of the salt, from 5 to 20 grains.

CALCIUM SALICYLAS ($\text{Ca}[\text{C}_7\text{H}_5\text{O}_2]_2 \cdot 2\text{H}_2\text{O}$).—Prepared by neutralizing a hot aqueous solution of salicylic acid with calcium carbonate, and filtering, or by decomposing sodium salicylate in solution with calcium acetate. It is a gritty, crystalline, white powder, feebly soluble in cold water (1 in 2000), and without taste or odor. Diluted acetic, sulphuric, hydrochloric, and nitric acids dissolve it. In doses of 5 to 25 grains it has been employed in the *diarrhoeal disorders of children*. It is not, however, very highly valued.

CALCIUM DITHIO-CARBONATE (CaCOS_2), *Dithio-carbonate of lime*.—An hygroscopic, orange-red, crystalline powder, sparingly soluble in water and in alcohol. In aqueous solution, if exposed to the air, it decomposes, sulphur and hydrogen sulphide being among the products. Pyogenic bacteria are said to be inhibited, but not destroyed, by a 1 per cent solution (Sabbadini). Upon the human skin, irritation, burning, and pustulation may result from the application of a 20 per cent solution. Locally, it has been applied to stubborn *skin affections*, such as *murulent venereal ulcers*, *eczema*, *lupus*, *psoriasis*, and other cutaneous disorders.

CROCUS (U. S. P.)—SAFFRON.

"The stigmas of *Crocus sativus*, Linné"—(U. S. P.).

Nat. Ord.—Iridæ.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 274.

Botanical Source.—Saffron is a perennial herb, with a roundish cormus; the integuments consisting of parallel fibers, distinct at the upper end. The leaves are radical, very narrow, linear, long, flaccid, revolute at the margin, with a longitudinal, white furrow above, and surrounded at the base with long membranous sheaths. The flowers are large, axillary, nearly or quite sessile on the bulb, with a 2-valved membranous, thin, transparent, radical spathe, appearing with the leaves, triate, with a long white tube, and purple, elliptical segments. The style is filiform, with 3 stigmas deeply divided, linear wedge-shaped, and of a deep-orange color, hanging down on one side of the flower, fragrant, and notched at the points. The capsule is 3-celled, and many-seeded; the seeds roundish (L.—W.).

History.—Saffron is indigenous to Asia Minor, and is much cultivated in some parts of Europe. The greater portion in this country is shipped from Spain and France. The former country sends *Spanish Alicante*, or *Valencia saffron*, which is admixed, to some extent, with other varieties. The latter are considered objectionable by the U. S. P. France sends *Gâtinais*, or *French saffron* which is a better grade than the Spanish. English and Austrian saffron are both

Fig. 89.

Crocus sativus: style with stigmas.

of very fine quality, but do not reach our markets. Saffron is also cultivated in the United States, notably in Pennsylvania. The Pennsylvanian product, which is of first quality, is often termed *American saffron*, a term which should not be confounded with that of the florets of another plant—the *Carthamus tinctorius*—which is the true *American saffron*. The so-called *African saffron* is usually *Carthamus* florets, though the flowers of a south African plant (*Lyperia crocea*, Ecklon), of the natural order *Scrophulariaceæ*, have passed under that name. Saffron requires a rich soil, and the yield per acre is said to be about 35 pounds. Saffron blossoms in autumn, the flowers are in abundance, and mantle the fields with a flax-gray covering. Each flower has one style, on the summit of which are the smooth, shining, dark, orange-red stigmas. The flowers are gathered early in the morning, just before they open; the stigmas are picked out, very carefully dried by the heat of a stove, and sometimes compressed into firm cakes. Five pounds of fresh saffron are required to yield one pound of dry (*Ed.*). The other parts of the flower are useless; of the stigmas it takes 70,000 to make one pound of saffron (P. L. Simmonds, *Amer. Jour. Pharm.*, 1891, p. 200). Saffron of commerce was formerly of two kinds, viz.: The *Hay saffron*, which is the best, and at present alone in use, consisting simply of the stigmata entangled together, and retaining their original deep-orange color; and the *Cake saffron*, which is in flexible cakes, about half a line in thickness, and of a dirty, brownish, orange tint, made by beating the stigmata together before they are quite dry.

Description.—The *U. S. P.* thus describes saffron: "Separate stigmas, or three, attached to the top of the style, about 3 Cm. ($1\frac{1}{4}$ inch) long, flattish-tubular; almost thread-like, broader and notched above; orange-brown; odor strong, peculiar, aromatic; taste bitterish and aromatic"—(*U. S. P.*). Saffron imparts its properties to water, vinegar, or spirit. The best saffron is that which is recent, being very slightly damp, not readily reduced to powder, of a strong, acrid, diffusive odor, but free from any disagreeable smell when burned; it imparts a soapy-like touch between the fingers, coloring them orange. On account of the great volatility of the aromatic part of the saffron, it should be wrapped in bladder, and preserved in a box, or tin case (*Ed.*).

Chemical Composition.—The yellow aqueous-alcoholic extractive matter obtained in the early analyses of saffron by Vogel, Bouillon-Lagrange (1811), and Aschoff (1818), was called *polychroit*, on account of its property of changing color when acted upon by certain reagents. It was first obtained pure by Quadrat, in 1851, and named *crocine* by Rochleder and Mayer, in 1862, who found it identical with the yellow coloring matter of *Gardenia grandiflora*, Loureiro, and established its glucosidal nature. When heated with acids, it splits into sugar and *crocetin* which Weiss (1868) proposed to call *crocine*, and retain the older name (*polychroit*) for the mother-substance.

R. Kayser (*Amer. Jour. Pharm.*, 1885) obtained *crocine* by first depriving saffron of its fatty matter by means of ether, extracting the coloring matter with cold water, and removing it from its aqueous solution by shaking with bone-charcoal, washing with cold water, evaporating to dryness, and extracting the coloring matter with 90 per cent alcohol, which upon evaporation left *crocine* as a brittle residue. It is soluble in water and dilute alcohol, less soluble in absolute alcohol, almost insoluble in ether. Its formula is $C_{44}H_{56}O_{11}$. In strong sulphuric acid it dissolves with blue color, which first turns to violet, then cherry-red, and subsequently to brown. Heated with weak bases (e.g., baryta water), it is converted into *crocetin* ($C_{44}H_{56}O_8$), insoluble in pure water, soluble in alcohol and alkaline liquids, and a peculiar sugar not quite identical with dextrose, hence called *crocose*.

Picro-crocine, or *Saffron-bitter* ($C_{44}H_{56}O_{11}$), Kayser observed to crystallize from ethereal extracts of saffron in colorless prismatic needles, melting at $75^{\circ}\text{C.}(167^{\circ}\text{F.})$, and having a bitter, persistent taste. Soluble in water and alcohol, sparingly soluble in ether. It is a glucosid which, when acted upon by weak bases, resolves into *crocose* and a volatile oil (terpene, $C_{10}H_{16}$), which has the characteristic and intense odor of saffron. The same oil was prepared by R. Kayser by distilling saffron with steam in a current of carbonic acid gas.

Adulterations and Tests.—Muscular fibers are said to have been used as an adulterant. They may be known by the odor of burning flesh, emitted on

burning the suspected article. Rubbing between the finger and thumb, without staining the skin yellow, indicates that the saffron has been exhausted by water or spirit. According to J. Müller, genuine saffron immediately assumes an indigo-blue color, when acted upon by chemically pure sulphuric acid, while the adulterations remain unchanged (*Chem. Gaz.*, May 1845, p. 197).

Saffron has ever been liable to various forms of adulteration, and the practice does not seem to have abated. It is frequently substituted in part, or entirely replaced by the florets of *Carthamus tinctorius*; yet substitution in this case may rather be due to ignorance, owing to the misleading name *American saffron*, affixed to this plant. Other substitutes are the worthless yellow styles of its flowers, or the florets of *Calendula officinalis*, the flowers of *Arnica montana*, the petals of red poppy, especially cut into shape for this purpose (C. Bernbeck, 1882), etc. Saffron is sometimes weighted by the addition of oil, or glycerin, or water, the gain from the latter source often being attained by storing the drug in damp places. Thus Dr. Niederstadt, in 1887, observed in "good" Spanish saffron 20 per cent of moisture, while genuine saffron contains from 10 to 12 per cent (Cæsar and Loretz, 1891). Sand and other mineral matters, as calcium sulphate, barium sulphate, or soluble salts, as sodium sulphate (Beringer, *Amer. Jour. Pharm.*, 1889) have been used as adulterants of saffron, and are admixed by means of honey or syrup. These additions (if they do not consist of ammonium salts) naturally increase the amount of ash, which should be about 5 per cent in good saffron. Adulteration of saffron with barium sulphate has been detected by Morpurgo (*Drug. Circ.*, 1897, p. 129), microscopical examination having revealed abnormal crystals within the cells. Closer examination showed that the drug had been soaked in solution of a barium salt and then treated with solution of a soluble sulphate. In a similar sophistication with barium sulphate, the ash amounted to 60 per cent (*Vierteljahrsschrift von Hilger*, etc., 1896). The addition of sugar, according to Dr. Niederstadt, is difficult to detect, since sugar is a natural constituent of saffron, amounting to 15 per cent. Another adulteration often reported, is the admixture of a large proportion of shredded fibers of sedge grass, tinged with safranin (a coal-tar color), or with some nitrophenol compound (related to picric acid). Saffron may also be exhausted of its color and then dyed with yellow aniline or other yellow.

The U. S. P. provides the following tests for saffron: Saffron should not include the yellow styles. When pressed between filtering paper, it should not leave an oily stain. When chewed it tinges the saliva deep orange-yellow. When soaked in water, it should not deposit any pulverulent, mineral matter, nor show the presence of organic substances differing in shape from that described. On agitating 1 part of saffron with 100,000 parts of water, the liquid will acquire a distinct yellow color. No color is imparted to benzin agitated with saffron (absence of picric acid and some other coal-tar colors). On drying saffron at 100° C. (212° F.), it should not lose more than 14 per cent of its weight (absence of added water). When thus dried, and ignited with the free access of air, 100 parts of the dry saffron should not leave more than 7.5 per cent of ash (absence of foreign inorganic substances).

Action, Medical Uses, and Dosage.—Emmenagogue and diaphoretic. It has been reputed of benefit in *amenorrhœa*, *dysmenorrhœa*, *chlorosis*, *hysteria*, and in *suppression of the lochial discharge*. It arrests chronic discharges of blood from the uterus. In *menorrhagia*, with dark clotted losses, give 5 drops of specific crocus, or a teaspoonful of the infusion several times a day. Saffron is not the important drug it was at one time. Like many of the old remedial agents, it is being supplanted by others that serve better the purpose. As a diaphoretic, it is used in *febrile and exanthematous diseases*, especially of children. In the latter it assists in producing the eruption, and is valuable in cases of retrocession of the same. Many consider this valuable agent as inert. Dose of the powder, from 12 to 40 grains; of the tincture or syrup, from 1 to 2 fluid drachms; of the infusion (saffron, 3j; hot water, Oj.), from 1 to 3 fluid ounces. Saffron is recommended for coloring tinctures, etc., but it is too costly an article for this purpose.

Related Species.—*Gardenia grandiflora*, Loureiro; *Gardenia radicans*, Thunberg; *Gardenia florida*, Linné. *Nat. Ord.*—Rubiaceæ. Europe and south Asia. The berries of these shrubs are used as a refrigerant and demulcent. The fruit pulp contains a coloring material identical with *polychroil*, and has been used in the Orient to impart a yellow color to fabrics.

CUBEBA (U. S. P.)—CUREB.

"The unripe fruit of *Piper Cubeba*, Linné filius" (U. S. P.) (*Cubeba officinalis*, Miquel).

Nat. Ord.—Piperaceæ.

COMMON NAME: *Cubebs*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 243.

Botanical Source.—This is a perennial plant, with a climbing stem, whose branches are round, of the thickness of a goosequill, ash-colored, smooth, and rooting at the joints; and when very young are minutely downy, as well as the petioles. The leaves are 4 to 6½ inches long by 1½ or 2 inches broad, petioled, oblong, or ovate-oblong, acuminate, rounded, or obliquely cordate at base, strongly veined, netted, coriaceous, and very smooth. The flowers are dioecious, and arranged in spikes at the end of the branches opposite the leaves, on peduncles the length of the petioles. The fruit is rather longer than that of black pepper, globose, and borne on pedicels from ½ to ¾ inch long (L.).

History and Description.—*Piper Cubeba* inhabits Java and Prince of Wales Island, Sumatra, Southern Borneo, and other isles in the Indian ocean, growing without cultivation in the forests. They are also cultivated to some extent in the coffee plantations of Java, being easy to grow when placed so as to climb the shade trees which are necessary in a coffee plantation. The fruit is gathered before it is fully ripe, and when dried is the part used in medicine. The fruit or berries are nearly globular, rough, grayish, somewhat lighter-colored than black pepper, of a rather pleasant, aromatic odor, and a hot, bitter, and somewhat camphoraceous taste. The cortical portion appears to have been thinner and less succulent than in black pepper, and contains within it a hard, spherical seed, which is whitish and oily. Cubebs are officially described as follows: "Globular, about 4 or 5 Mm. (¼ to ½ inch) in diameter, contracted at the base into a rounded stipe about 6 or 8 Mm. (¼ to ½ inch) long, reticulately wrinkled, blackish-gray, internally whitish and hollow; odor strong, spicy; taste aromatic and pungent. Cubeb should not be mixed with the nearly inodorous rachis or stalks"—(U. S. P.). The volatile oil is much used in medicine. The powder of cubeb becomes inert after a time, in consequence of the loss of its volatile oil; hence, it is better to powder the drug only as required for use.

Chemical Composition.—The more important constituents of cubebs are: Volatile oil (see *Oleum Cubebæ*), fatty oil, *cubebin*, *cubebic acid*, and indifferent *cubeb-resin*, the latter two substances alone carrying the diuretic qualities of the drug. Calcium and magnesium malates are also present. Cubebin, cubebic acid, and cubeb resin may be obtained in one operation according to explicit directions given by E. A. Schmidt in *Archiv. der Pharm.*, 1870, pp. 1–49. *Cubebin* ($C_{20}H_{30}O_2$, according to Weidel, 1877), first obtained pure by Soubeiran and Capitaine, in 1839, is present in about 2.5 per cent (Schmidt). It is an indifferent, crystallizable substance without taste or odor, but is bitter in alcoholic solution. It melts at 125° C. (257° F.), is insoluble in cold, and but little soluble in hot water; requires 76 parts of absolute alcohol for solution, and is much less soluble in weak alcohol. It is also soluble in about 27 parts of ether, likewise in benzene, acetic acid, and chloroform, the solution in the latter solvent being lævo-rotatory. Cubebin is soluble in concentrated sulphuric acid with blood-red color (Husemann and Hilger, 1882). Weidel (1877) found that when fused with caustic potash, cubebin yields carbonic acid, acetic acid, and *protocatechuic acid* ($C_6H_3[OH]_2COOH$). This fact, in connection with the observation of Pomeranz (1887), to the effect that cubebin yields, upon oxidation *piperonylic acid* ($C_6H_3:[O.O.CH]_2COOH$), establish it to be a derivative of *pyrocatechin* (ortho-dioxybenzene) ($C_6H_2[OH]_2$). *Cubebic acid* ($C_{20}H_{30}O_3$, Schmidt; $C_{20}H_{30}O_3.H_2O$, Schultze, 1873), was obtained by Schmidt in the quantity of about 1.7 per cent. When pure it forms a white, resinous mass, insoluble in water, soluble in alcohol, ether, chloroform, stronger water of ammonia, and caustic alkali. It forms salts with alkalies and the bases of heavier metals, the former being soluble in water. The sodium salt was obtained in crystals by Schultze. Concentrated sulphuric acid dissolves cubebic acid with crimson color, a reaction pointed out by E. M. Holmes (1885), as useful

in the detection of adulteration by "false cubebs" (see *Related Species*). *Cubeb resin* ($C_{15}H_{10}O_2$) is an indifferent substance, soluble in alcohol and alkalies, sparingly soluble in chloroform, ether, and carbon disulphide. The yield is from 2 to 3 per cent. F. V. Heydenreich (1868) instituted a series of experiments to determine whether the active principle of cubebs resided in its oil, its oleoresin, or in the cubebin. He concluded that the diuretic property of cubebs resides in its soft resin (now known as being composed of *cubebic acid* and *cubeb resin*); that cubebin is comparatively inert; and that the volatile oil is carminative and stimulant, producing in large doses the irritation common to analogous oils. These results were confirmatory of those previously announced by Bernatzik (1863).

Action, Medical Uses, and Dosage.—Cubebs are mildly stimulant, expectorant, stomachic, and carminative. They act more particularly upon mucous tissues, arresting excessive discharges, especially from the urethra. In large doses they produce increased frequency and fullness of pulse and augmented heat; occasionally they cause nausea, vomiting, burning pain, griping, or even purging. Sometimes they cause a rash-like eruption on the skin. They exercise an influence over the urinary apparatus, frequently producing diuresis, rendering the urine of a deeper color, with a peculiar, aromatic odor. They have been successfully employed in *gonorrhœa*, *gleet*, *leucorrhœa*, *catarrh of the urinary bladder*, *chronic inflammation of the bladder*, *abscess of the prostate*, *chronic laryngitis* and *bronchitis*, *dyspepsia* due to an atonic condition of the stomach, etc. Generally, it is better to use them after the high inflammatory symptoms have subsided. If they do not afford benefit very soon, they should be used no longer. There has been much controversy as to whether this drug should be employed during the active stage of gonorrhœa, or after the active symptoms have subsided. Prof. Locke, whose experience has been large, declares in favor of it after the active inflammatory stage has passed, and that it should be employed only after the profuse discharge has ceased. He believes it contraindicated in all inflammatory states, and prefers it in the *chronic form of gonorrhœa*, believing it more successful than in the acute. In chronic gonorrhœa, 30 grains of the powdered berries are to be given 3 times a day to produce an aggravated condition of the disease—a substitutive inflammation—and as this passes off the disease is decidedly better. This method should be persisted in until urination is painful, and then the dose should be lessened from day to day until a cure is effected. Christison states that he has known the use of cubebs to be frequently attended, like copaiba, with an ephemeral synocha, followed by a prompt cessation of the gonorrhœal discharge; in which disease they may be given in powder, along with water or milk, or made into a paste with copaiba. The following preparations have been successfully used in *gonorrhœa* and *gleet*: 1. Take of ethereal extract of cubebs, solidified balsam of copaiba, and carbonate of iron, of each 2 drachms; resin of podophyllum, 10 grains. Mix, and divide into pills of 4 grains each, of which 1 or 2 may be given 3 times a day. 2. Take of pulverized cubebs, podophyllum, white pond lily, of each $\frac{1}{2}$ ounce; Holland gin, 1 pint; macerate for several days, and give sufficient doses 3 times a day to act slightly on the bowels. 3. Take of solidified copaiba 2 ounces, ethereal extract of cubebs 1 ounce, oil of juniper a sufficient quantity; mix and divide into pills of 4 grains each, of which 1 or 2 may be taken 3 times a day. Not only does cubeba affect the urinary tract, but it acts upon all the mucous tissues of the body, restraining profluvia, giving tone, besides augmenting the appetite and improving digestion. While contraindicated in acute inflammations it is often of service in *chronic inflammations*. When in *leucorrhœa* the discharge is copious and offensive, give large doses (30 to 40 grains 3 times a day), until a decided effect is made; then diminish the dose from day to day. *Chronic inflammatory states of the female bladder and urethra*, with constant urging and painful efforts to urinate, are relieved by 5-drop doses of specific cubebs given every 3 or 4 hours. *Spermatorrhœa*, *cystic catarrh*, *nocturnal urinal incontinence* of children, and *prostatic abscess*, are all benefited when the conditions are first aggravated by the larger dose, and the drug lessened as the treatment progresses. The urethral burning is the indication for it. The greater the debility the more pronounced are its effects. Use it for the scalding sensations often experienced by women in urinating, a condition common to the menstrual period, and for irritation and burning of the vulva. Prof. Scudder suggests the small

dose "in debility with irritation of the reproductive apparatus, prostaticorrhea, uneasiness and formication of the scrotum and anus, and diseases associated with reproductive weakness."

Atonic respiratory troubles with profuse expectoration, are benefited by 5 to 10 drop doses of specific cubeba on sugar every hour. It has been given in this manner and the berries smoked for the relief of *nasal catarrh*. The latter procedure is often beneficial in *hay fever*. Equal parts of black German snuff and powdered cubeba are stimulating and alterative in excessive catarrhal states of the nasal membranes; snuff into the nostrils several times a day (Locke). M. Trideau found a syrup of cubeba, in connection with one of copaiba, to be almost a specific in *croup*. M. Berjeron has also met with great success in the same disease, but he prefers to administer the oleoresin of cubeba either in capsules or in emulsion, having the children take according to their ages from 15 to 60 grains per day. **Chronic sore throat** with great relaxation of the membranes and excessive secretion is benefited by specific cubeba suspended in syrup. Dose of cubeba in powder, from 5 grains to 1 drachm 3 times a day; of the tincture, $\frac{1}{2}$ to 2 fluid drachms; of the oil, from 5 to 30 drops; of specific cubeba, 1 to 60 drops.

Specific Indications and Uses.—Latter stage of gonorrhœa, after profuse discharges have ceased; chronic gonorrhœa; enfeebled states of the large intestine and rectum; subacute inflammations of the urinary passages; urethral burning; scalding of urine in females; irritation and burning of vulva; debility with profuse discharges from the mucous tissues.

Related Species and Products.—*Piper Clusii*, Cas. De Candolle (*Cubeba Clusii*, Miquel; *Piper Afzelii*, Lindley). This plant, from French Africa, furnishes a drug supposed to be more closely allied to black pepper than to cubeba; it almost always has a long stalk attached, and its size is about one-half less than that of the commercial drug. The color is ashen-gray, and the taste hot. It is known as *African pepper*, *African cubeba*, *West African black pepper*, *Ashantee pepper*, and *Guinea pepper*. The plant with its ripened cluster of red fruit is regarded as one of the handsomest and most conspicuous specimens of African vegetation. Stanislas Martin found the chemical composition of African pepper to be nearly the same as the Sumatra or Malabar cubeba, and believes it to possess the same properties as these, provided it be perfectly cleansed of its stalks. Stenhouse, however, in 1855, states that its proximate constituent is *piperine*, and not cubebin, thus bringing it closer to pepper than to cubeba. These berries are used as a condiment in tropical West Africa.

OTHER SPECIES.—The following plants also yield berries that more or less resemble cubeba, and some of which have been used as substitutions therefor. They are called "false cubeba," *Cubeba Loung*, Miquel (*Piper Loung*, Blume); *Cubeba canina*, Miquel (*Piper caninum*, Dietrich); *Cubeba Wallichii*, Miquel (*Piper ribesoides*, Wallich); *Cubeba crassipes*, Miquel (*Piper crassipes*, Korthals), probably the *Piper anisatum* of Humboldt and Bonpland; and *Laurus Cubeba* Loureiro (see *Pharmacographia*). Mr. Holmes recommends as a useful test the bright, indigo-blue coloration that the genuine drug yields with solution of iodine, both in the form of powder and decoction (undoubtedly due to the action of iodine upon the essential oil of cubeba, and not to the presence of starch, as has been suggested), and the crimson color the drug imparts to strong sulphuric acid (see paper on this subject by E. M. Holmes, in *Pharm. Jour. Trans.*, Aug., 1892, or *Amer. Jour. Pharm.*, 1892, p. 494).

CUMINUM.—CUMIN.

The fruit of *Cuminum Cyminum*, Linné.

Nat. Ord.—Umbelliferae.

COMMON NAME: Cumin.

Botanical Source.—This is an annual herb, with an erect, round, slender, branched stem, about a foot high. The leaves are multifid, with long, filiform segments. The flowers, small, white, or pink, are overtopped by the bracts, which, after flowering, are reflexed. The umbels, both partial and general, consist of about 5 rays, with the involucre consisting of 2 or 3 filiform, 1-sided bracts. The fruit is about 2 lines in length, much longer than the pedicels, nearly tapering, but little contracted at the sides, fusiform, crowned by the short teeth of the calyx, densely covered with short rough hair upon the channels, and less densely upon the ridges, which are paler, filiform, and a little raised; the seeds or half-fruits, 2 in number, are oblong, plano-convex, with the plane surfaces together (L.).

History and Description.—This plant is cultivated in many parts of Europe though originally from Egypt. It is referred to in Scripture (Isaiah xxviii, 25-27,

and Matt. xxiii, 23), and was a lesser titheable product in Palestine (*Pharmacographia*). The fruit or seeds are ovate or fusiform, of a light-brown or grayish color, with 2 adhering concavo-convex fruits. The fruit resembles caraway, but is larger. Each seed or fruit presents 5 filiform, rough, primary ridges, between which are 4 secondary ones, which are furnished with small prickles. Between each primary ridge is an elongated oil tube (vitta) besides 2 vittae on the face of the mericarp. Insects often destroy the fruit. Their odor and taste is similar to that of caraway, but warmer, and not so agreeable.

Chemical Composition.—Bley (1829) found the fruit to contain resin, fatty matter, gum, lignin, protein bodies, salts, largely composed of malates, extractive, and volatile oil. The volatile oil, which is the chief constituent, may be separated by distillation with water, and is of a yellowish color, thin, having a specific gravity varying from 0.890 and 0.930 at 15° C. (59° F.) (Schimmel & Co.), and possessing the taste and odor of the plant. This oil is a compound, consisting mainly of 2 oils, viz.: Cymol (*cymene*, or para-methyl-propyl-benzene, $C_{10}H_{14}$), a hydrocarbon having the odor of lemons; cuminol (cumin-aldehyd) ($C_{10}H_7[C_2H_5]CHO$), an oxygenated substance possessing the odor of caraway. Lastly, a terpene, having the composition $C_{10}H_{16}$, was believed to have been obtained, in 1896, by Wolpian (see Schimmel's *Report*, Oct., 1896). When treated with nitric acid, cumin-aldehyd is oxidized to crystallizable *cuminic acid* ($C_{10}H_7O_2$). Trapp (1858) obtained from the seeds of *Cicuta virosa*, Linné, essential oils identical with those of cumin oil. The yield of oil of cumin from raw material, according to Schimmel & Co. (*Semi-annual Report*, Oct., 1893), is as follows: From Syrian fruit, 3 to 4 per cent; Maltese fruit, 3.5 per cent; Moroccan fruit, 8 per cent; East Indian, 3 to 3.5 per cent. Cymol has a density of 0.860 at 15° C. (59° F.), and boiling point near 174° C. (345.2° F.). Cuminol has a density of 0.972 at 15° C. (59° F.), and boiling point near 229° C. (444.2° F.). Schimmel & Co. report in October, 1896, that the demand for cumin oil has been constantly decreasing and is now inconsiderable.

Action, Medical Uses, and Dosage.—Highly stimulant and carminative, possessing medical properties similar to the other aromatic fruits of umbelliferous plants, but more stimulating. They are seldom used in the United States. Dose, from 15 to 60 grains.

Related Drugs.—**NIGELLA.** *Fennel flower.* The seeds of two ranunculaceous plants, the *Nigella sativa*, Linné, *Nutmeg flower*, or *Small fennel flower*; and *Nigella damascena*, Linné, or *Ragged Lady*. They are natives of Syria and south Europe, and are cultivated in gardens. The leaves of these plants resemble those of fennel. The seeds of the first species are rough, triangular, ovate, two surfaces being flat and the other convex, about $\frac{1}{16}$ to $\frac{1}{8}$ inch long, externally dull-black, and internally white and oleaginous. To the taste they are acrid, somewhat spicy, and pungent. In odor they are aromatic or camphoraceous, reminding some persons of nutmegs, others of cajuput. The seeds of *ragged lady* are occasionally sold under the name *magnolia seeds*. They have rounded angles, and a deeply-netted and corrugated testa. When rubbed they exhale an odor comparable with that of strawberries. The seeds of *nutmeg flower*, according to Husemann and Hilger, contain 1.5 per cent of an essential, colorless and fluorescent oil, and consists of a substance $C_{20}H_{30}O$ and a terpene (Flückiger). Its odor differs from that of the seeds, and a fixed oil to the extent of 35 per cent, was obtained by Reinsch, in 1841. Flückiger has shown it to be composed of myristin, stearin, and palmitin. A yellow extract-like mass, having a bitter taste, was isolated by Reinsch and named *nigellin*. It is not, however, regarded as a distinct body.

Melanthin ($C_{20}H_{30}O_7$), a glucosid, was isolated by H. G. Greenish, in 1880. It is amorphous, acrid, foams when shaken with water, is very soluble in alcohol, but scarcely soluble in water, benzin, benzol, ether, and carbon disulphide. Acids split it into glucose and *melanthinigenin* ($C_{14}H_{20}O_5$). Both principles impart a rose-red tint with pure sulphuric acid in about 15 minutes. The color changes to violet-red upon long standing. The seeds of *Nigella damascena* were observed by Greenish to yield to petroleum benzin a fluorescent principle, but contain no melanthin (*Amer. Jour. Pharm.*, 1882, pp. 10 and 804), and A. Schneider (1890) showed that this was due to a crystalline alkaloid which he named *damascenine*, the compounds of which, however, are non-fluorescent.

CUNILA.—DITTANY.

The whole herb of *Cunila mariani*, Linné.

Nat. Ord.—Labiatae.

Common Names: *American dittany*, *Mountain dittany*, *Stonemint*.

Botanical Source.—This is an indigenous, perennial plant, with a fibrous root, and smooth, slender, 4-angled, mostly purplish, corymbose branched stems,

growing 1 or 2 feet high. The leaves are opposite, small, nearly smooth, ovate, serrate, subsessile, roundish or subcordate at the base, tapering to a point, and punctate with pellucid dots. The flowers are white or pale-red, pedunculated, with subulate bracts at the base of the 3-forked pedicels, in corymbose, axillary, and terminal cymes. The corolla is nearly twice as long as the calyx, pubescent, middle lobe longer than the others, upper lip erect, flat, emarginate, and lower lip spreading. The calyx is green, 10-ribbed, equally 5-toothed, hairy in the throat, and punctate. Stamens 2, erect, exserted, distant. Anthers small, didymous; stigma bifid, exserted; seeds 4, small, obovate (W.—G.).

History and Chemical Composition.—Dittany is found growing in dry hills and woods, and on rocks, in nearly all parts of the United States, flowering from June to October. The herb is very fragrant, with a warm, spicy taste; its taste and odor are due to a volatile oil which may be procured by distillation. Mr. P. Milleman found the herb to contain a warm, pungent, delicately fragrant, volatile oil, tannic acid, a trace of glucose, gummy matter, considerable extractive matter, a part of which was bitter and acid, and dark-green resin; the ashes gave salts of potassium, calcium, magnesium, and iron (*Amer. Jour. Pharm.*, 1866, p. 495).

Action, Medical Uses, and Dosage.—Stimulant, carminative, antispasmodic, and diaphoretic. Used freely in warm infusion to promote perspiration, to relieve flatulency, and as an emmenagogue. Popularly employed for colds, headaches, and fevers; also to relieve nervous headache, and hysterical disorders, colic, indigestion, and many nervous affections. The volatile oil possesses all the medicinal properties of the herb, and may be given in doses of from 5 to 10 drops.

Related Species.—*Dictamnus albus*, Bastard dittany, *White fraxinella*. A bitter, aromatic root-bark used by Baron Störck for worms, epilepsy, hysteria, amenorrhœa, and intermittent fevers. Dose, 20 to 60 grains.

CUPRI ACETAS.—COPPER ACETATE.

Formula: $\text{Cu}(\text{C}_2\text{H}_3\text{O}_2)_2 + \text{H}_2\text{O}$. **MOLECULAR WEIGHT:** 198.86.

SYNONYMS: *Crystallized ærugo*, *Crystallized verdigris*, *Copper verditer*, *Flora viridis æris*, *Cupric acetate*, *Acetas cupricus*, *Cuprum aceticum*, *Æruga crystallisata*, *Æruga destillata*.

Preparation.—Acetate of copper is prepared by dissolving subacetate of copper (verdigris), in an excess of acetic acid, adding a small portion of water, filtering, and crystallizing the filtrate by evaporation. It may also be prepared by the double decomposition of lead (or calcium) acetate and copper sulphate. It was known to the Arabs, who obtained it by dissolving verdigris in warm vinegar, decanting the supernatant fluid, evaporating in copper receptacles, and finally crystallizing the salt in wooden vessels.

Description.—The neutral acetate of copper, or crystallized ærugo, also called *Crystals of Venus* ($\text{Cu}[\text{C}_2\text{H}_3\text{O}_2]_2 + \text{H}_2\text{O}$), is little used in medicine as such, but is employed in the form of an alcoholic solution known as *Rademacher's Tincture of Acetate of Copper*. It forms small, dark-green, rhombic prisms, inclining to a bluish hue, of a feeble, acetous odor, a nauseous, metallic taste, efflorescent, soluble in 5 parts of boiling water (15 of cold), partially soluble in alcohol (14 parts of hot and 135 of cold), inflammable, burning in the open air with a beautiful green flame. Its solution in water is bluish-green, and when boiled evolves acetic acid and precipitates a basic salt colored dark-blue by ammonia water (or ammonium carbonate) in excess. Stronger mineral acids liberate acetic acid from it.

TINCTURA CUPRI ACETI RADEMACHERI.—*Rademacher's Tincture of Acetate of Copper.* Take crystallized copper acetate 1 part, warm water 10 parts; solve. Add to the solution alcohol 8 parts. "The original process of Rademacher was by the double decomposition of crystallized sulphate of copper and crystallized acetate of lead, and we prefer it at the present day. It is as follows: Take of crystallized sulphate of copper and of crystallized acetate of lead, each 3 troy ounces; water, 17 fluid ounces; alcohol, 13 fluid ounces. Powder the salts separately, and then rub them together in a mortar until they assume a pasty condition. Then gradually add the water, and afterward the alcohol. Place the mixture in a bottle, and after 14 days, carefully decant the clear dark-green or blue solution

from the precipitate of lead sulphate, and filter it through paper" (Lloyd's *Chemistry of Medicines*, p. 262).

Action, Medical Uses, and Dosage.—I. **CUPRUM**, or *Copper*. Metallic copper seems to have but little influence upon the human system. Copper workers, who are constantly exposed to its dust, are not poisoned by it, though they are usually somewhat anemic and experience sensations of lassitude, vertigo, and gastric disturbances. Their gums present a greenish or olive-colored line, and their teeth, which also present the same discolorations, are often lost at an early day. They seem to be peculiarly free from choleraic and typhoid diseases. Those who work in copper leaf (bronze powder) are said to become subject to either diarrhoea or constipation, with abdominal tenderness and colic, nausea, vomiting, and have a retracted gum with a purplish line or edge, and a peculiar anemic appearance, emaciation, cough, and lack of muscular power. More recent experiments have demonstrated the fact that copper is at least not a cumulative poison, *e. g.*, as lead, and the so-called "*colique de cuivre*," asserted in the eighteenth century to be a definite disease, does not exist (*Amer. Jour. Pharm.*, 1884, p. 293). The soluble copper salts, however, produce a coppery taste, nausea, vomiting, severe colic, frequent bloody or black stools, quick, small, irregular, and sharp pulse, burning and thirst, syncope, dyspnoea, suppression of urine, or scanty urine, burning when being voided, intense headache, cramps and spasms, and finally death. This extreme action, however, is rare.

II. *Cupric acetate* in the form of Rademacher's tincture is quite extensively employed in our school as a blood maker. Prof. Scudder preferred *greened pickles* to any other form of administration, and he points out the cases requiring *cuprum* (as the greened pickles and tincture of the acetate are known in Eclectic therapy), as those of *anemia* without great loss of flesh, the surface "pallid, yellowish, greenish, or sometimes tawny, skin waxy, parts usually colored with blood, pale, with sometimes a greenish tinge." Tongue pale, broad, usually clean, bowels inactive, "pulse rather full, but without sharpness of stroke." He employed it in any condition of disease presenting these indications. *Leucocythemia*, *chlorosis*, and *anemia* yielded to it when other remedies failed. The soft, full, and doughy tissues gave way to firmer flesh, and the appetite and blood making were improved. It has been suggested (6x trit.) in *explosive cough*, meeting conditions similar to those calling for *drosera*. It is particularly recommended in *whooping-cough* with a tendency to convulsions. Its use in *paralysis* depending upon *sclerosis of the spinal cord* has been advised, as it has also in the later stages of *cerebro-spinal meningitis* where structural alteration is threatened. The general indications should guide to its selection. It should be remembered as a blood maker after severe hemorrhages or other *exhausting discharges*. Faulty nutrition in *diseases of the ear*, especially when dependent upon chlorosis, and with tinnitus as a prominent symptom, are admirably met with *cuprum*, $\frac{1}{2}$ to $\frac{1}{4}$ drop 4 times a day. Impaired hearing is usually present. Dose: Add of the tincture of the acetate or of specific *cuprum*, gtt. x to xx to aqua \mathfrak{z} iv, and give a teaspoonful 4 times a day. Of the 6x trituration 1 to 3 grains 3 or 4 times a day. The sulphate of copper in doses of $\frac{1}{16}$ to $\frac{1}{8}$ grain fulfil practically the same indications.

Specific Indications and Uses.—Skin tawny, dirty, yellowish, greenish, pallid, or waxy; parts usually red are pale or greenish; tongue broad, uncoated, and pale; gums blanched; pulse small, soft, and quicker than usual; bowels torpid with colorless discharges, and if loose, the pale evacuations resemble rice-water. Anemic states with dirty-greenish tinge, and without great loss of flesh; chlorosis; tissues full, but soft and doughy; after hemorrhages or exhaustive discharges as a bloodmaker, when the skin is pale and transparent.

Related Bodies.—**CUPRUM**. *Copper*. Symbol: Cu. Atomic weight: 63.18. This metal appears to have been known even before the time of Moses. It exists native in different parts of the globe, especially near Lake Superior, Michigan, and Chili, and is found in a great variety of compounds, principally in the form of *copper pyrites* (double sulphide of copper and iron (CuFeS_2 , or $\text{Cu}_2\text{S} + \text{Fe}_2\text{S}_3$)). *Copper glance* (cuprous sulphide), another copper mineral, has the composition Cu_2S . It is also found as *malachite*, a most beautiful velvety-green mineral, which is a combined copper carbonate and hydroxide ($\text{CuCO}_3 + \text{Cu}[\text{OH}]_2$). Both oxides of copper (CuO and Cu_2O) are occasionally found native. Copper is obtained from its ores by various metallurgical processes. In recent years the manufacture of copper by electrolytic decomposition of solutions of copper salts has been gaining ground. In the old

English process of *copper smelting*, the sulphur-bearing copper ores undergo several processes of roasting, iron slags being added at the proper stages, until nearly all the copper is converted into *white metal*, which is almost pure cuprous sulphide (Cu_2S). This is again roasted, resulting in the partial formation of CuO ; the mixture, upon fusion in properly constructed furnaces, next yields metallic copper and sulphurous acid, as follows: $2\text{CuO} + \text{Cu}_2\text{S} = 4\text{Cu} + \text{SO}_2$. The copper thus obtained (*blister copper*) is at last refined. Pure copper is a reddish, brilliant, ductile, sonorous, and malleable metal, of a nauseous, styptic taste, a peculiar disagreeable odor, harder than silver, fusing at 1091°C . (1996°F .), and on cooling it crystallizes in regular octahedrons and cubes. It is combustible, and is readily oxidized at a red heat, forming black scales on the surface. On exposure to moist air, it acquires a filmy-green coating of subcarbonate of copper (or, if exposed to a salty atmosphere, of subchloride of copper), and has the specific gravity 8.914 to 8.952. As a conductor of electricity and heat it is one of the best we possess. Nitric acid readily dissolves it, but cold sulphuric, or even hot sulphuric acid (diluted) has no action on it. Copper forms with oxygen principally 2 oxides and 2 lines of salts, known as the cuprous (lower) and cupric (higher). The copper directed by the *British Pharmacopœia* is copper wire of about No. 25 gauge. In case of poisoning with copper after vomiting has been induced, and the stomach pump applied, albumen should be freely administered; also reduced iron, iron filings, or ferrocyanide of potassium (yellow prussiate of potash) in dilution, may be given. (For action of copper, see *Cupri Acetas*).

Alloys of Copper.—Copper forms many useful alloys, the principal of which are as follows: **BRASS**—Copper 64, zinc 36; **BRONZE**—Copper 80, tin 16, zinc 4; **GUN METAL**—Copper 90, tin 10; **BELL METAL**—Copper 78, tin 22; **ALUMINUM BRONZE**—Copper 95 to 90, aluminum 5 to 10; **GERMAN SILVER**—Copper 51, zinc 31, nickel 18. The proportion of zinc in brass, however, is not always that given above, but may vary from 28 to 36 per cent. In fact, the proportion of parts in all alloys vary within certain limits. Both the brass and bronze of the ancients contained lead in addition to the other metals. A good *statuary bronze* is made of copper 91, zinc 6, tin 2, lead 1.

Pigments Prepared from Copper.—Several copper pigments are employed in the arts and occasionally in medicine. Sometimes they are adulterated with barium, calcium, iron, lead and aluminum compounds.

SCHÉELE'S GREEN. *Mineral green.*—A hydrogenated arsenite of copper (CuHAsO_3). Prepared by precipitating solution of sulphate of copper with that of potassium or sodium arsenite. A poisonous grass-green compound, insoluble in water. This compound, under the name *arsenite of copper*, has recently been employed in minute doses ($\frac{1}{15}$ gr. in water, $\frac{1}{15}$ vi; teaspoonful, frequently repeated), in *dysentery*, *cholera infantum*, and other *infantile diarrheas*.

PARIS GREEN. *Schweinfurt green, Mitis green, Emerald green.*—Chiefly composed of aceto-arsenite of copper ($3\text{CuAs}_2\text{O}_4 + \text{Cu}[\text{C}_2\text{H}_3\text{O}_2]_2$). A pale, grass-green, insoluble crystalline powder, the most poisonous of the cupro-arsenical compounds. It is extensively employed for the destruction of the Colorado potato beetle and other insects, and as a coloring material. It is prepared by boiling together arsenous oxide (As_2O_3) and verdigris.

BREMEN BLUE. *Bremen green.*—Usually hydroxide of copper, though the subcarbonate is sometimes sold for it. If used with oil, it turns green by forming a soap, but, if used with water only, it retains its blue color. Hence the two names.

BRUNSWICK GREEN may be either an oxychloride or an oxycarbonate of copper.

MOUNTAIN GREEN. *Mineral green* (Schéele's green is also called *Mineral green*).—Powdered malachite, or manufactured oxycarbonate of copper.

BLUE ASH.—A pigment prepared from the mineral *azurite* (*Mountain blue*), which is tri-cupric carbonate ($2[\text{CO}_3\text{Cu}] + \text{Cu}[\text{OH}]_2$). It is made by a secret method.

VERDIGRIS.—Two copper preparations, known as *Blue verditer* and *Green verditer*, are used as pigments. The former is obtained by treating copper nitrate with chalk or with lime. If chalk be used, the product is a copper carbonate; if lime is employed, a mixture of calcium and copper hydroxides results. Green verditer is chiefly a mixture of copper carbonate, with an excess of chalky material. It is prepared by the interaction of copper nitrate and calcium carbonate, or white marl.

Other Copper Compounds.—**CUPRUM AMMONIATUM.** *Ammoniated copper, Cupri ammonio-sulphas, Ammoniz cupro-sulphas, Cupro-sulphate of ammonia.* This salt is prepared by rubbing together until effervescence has ceased, 1 ounce of sulphate of copper with an ounce and a half of carbonate of ammonium; then place the residue in bibulous paper, and dry it on a porous brick. Finally, inclose in a well-stoppered bottle. The *U. S. P.* (1870) directed 3 parts of ammonium carbonate and 4 parts of copper sulphate, the product to be wrapped in bibulous paper, and dried by gentle heat. When prepared and made by the foregoing processes, the salt contains ammonium carbonate in excess. By dissolving 1 part of blue stone (copper sulphate) in 3 parts of ammonia water, and, after filtering, adding to the filtrate 6 parts of alcohol, the pure salt will crystallize either as a deep blue crystalline powder, or in the form of long, flat prisms and needles, having the composition $\text{CuSO}_4 \cdot (\text{NH}_3)_4 \cdot \text{H}_2\text{O}$. The salt has an odor of ammonia, and a nauseous, metallic taste. It dissolves in $1\frac{1}{2}$ parts of cold water, but is decomposed in a large quantity of water, a pale-blue powder (basic sulphate of copper) being precipitated; excess of ammonia will prevent this. Exposed to the air, it loses its ammonia, a green powder resulting, which, being carefully heated, leaves a white residue, the neutral sulphate of copper. Acids, lime-water, and the fixed alkalis, form precipitates with a solution of the cupro-sulphate of ammonium; arsenous acid, in solution, gives a precipitate of Schéele's green. It is said to be a tonic, and has been used in *chorea*, *hysteria*, *epilepsy*, *spasmodic asthma*, and *cramp of the stomach*, in doses of from $\frac{1}{4}$ grain, 2 or 3 times a day, cautiously increased to 5 grains. It is generally given in pill form, with crumb of bread and carbonate of ammonium. It

is said, in doses of 2 grains, 3 times a day (after meals), to be an efficient remedy in *neuralgia of the fifth nerve*. The usual medicinal dose of this salt is from $\frac{1}{4}$ to 1 grain. In solution (a drachm of the salt to a fluid ounce of water) it has been used as an application to indolent ulcers to stimulate them; and, still further diluted, to the eye, to remove slight specks on the cornea. In large doses it produces vomiting, purging, weakness, trembling, and paralysis. The antidotes are the same as named for poisoning by sulphate of copper.

OLEATE OF COPPER.—This product has been found of service in many forms of *tinea trichophytosis*. It is employed locally as an ointment of from 1 to 5 grains to 1 ounce of petrolatum. It is antiseptic, astringent, and antiparasitic.

CUPRI OXIDUM, Cupric oxide ($\text{CuO}=79.14$), *Copper monoxide, Black oxide of copper*.—This is found native as *melanconite*. It may be obtained by calcining well-washed and dried carbonate of copper (prepared by precipitating solution of blue vitrol with solution of sodium carbonate), and then by gradually heating it to redness in a Hessian crucible, the temperature being maintained about 30 minutes. When nearly cool transfer to glass-stoppered vials (Lloyd's Chemistry, p. 264). Black oxide of copper is a heavy, soft, amorphous powder, black in color, tasteless and odorless. It should dissolve, without effervescing, in diluted nitric acid, or other diluted acids that dissolve it. An ointment (4 parts to 30 of lard) has been used to discuss chronic glandular enlargements.

COPPER HYDROXIDE, Cupric hydrate ($\text{Cu}[\text{OH}]_2$).—Prepared by precipitating a solution of copper sulphate with a solution of an alkali. It is a blue substance that dissolves in ammonia to form a dark-blue fluid (the aqueous solution of the cuprum ammoniatum above described), which is capable of dissolving linen, cotton, and other "modifications of cellulose" (Lloyd's Chemistry, p. 264).

CUPRI NITRAS ($\text{Cu}[\text{NO}_3]_2 + 3\text{H}_2\text{O}$), *Copper nitrate, Cupric nitrate*.—According to the *British Pharmacopœia* cupric nitrate is prepared by dissolving fine copper wire (about No. 25 gauge) in diluted nitric acid and crystallizing the salt, when the solution is sufficiently evaporated to admit of the formation of crystals on cooling not lower than 21.1°C . (70°F). It crystallizes as dark-blue, deliquescent prisms of very corrosive action. It forms with $\frac{1}{2}$ of its weight of water (at a low temperature) a tabular salt of the composition $\text{Cu}[\text{NO}_3]_2 + 6\text{H}_2\text{O}$. By absorption of atmospheric vapor, or on the addition of a slightly increased amount of water, it yields a styptic, corrosive liquid. Crystals of cupric nitrate corrode the skin with great energy, are soluble in water or alcohol, and fuse when heated, parting with water and nitric acid, and leaving a green basic salt, which, still further heated, becomes pure oxide of copper. This salt has been used as a caustic to ulcers of various parts, as well as of the tongue and throat; the ulcer must first be dried, then apply the caustic, and cover the part with sweet oil (Braithwaite's Retrospect, Vol. XXV, p. 201).

CUPRI CHLORIDUM, Chloride of copper, Cupric chloride ($\text{CuCl}_2 + [\text{H}_2\text{O}]_2 = 134.2$).—This may be easily prepared in crystals by dissolving cupric oxide in chlorhydric acid, and evaporating the solution. The salt is deposited in rectangular prisms of a fine grass-green, or blue-green color. It is exceedingly acrid and caustic, has the specific gravity 1.87, is very soluble in water, attracts moisture from the air, forming an oily liquid, and fuses at a moderate heat, becoming solid when cold. In doses of from 2 to 10 grains, in the form of pill or solution, it is said to be useful in *epilepsy*. The solution may be used externally for the same purpose as that of the nitrate of copper.

COPPER CARBONATE.—This is the compound found on copper (copper rust), when the latter is exposed to the atmosphere. It is also known as basic carbonate and subcarbonate of copper. When freshly made, by precipitating copper sulphate solution with solution of sodium carbonate, the bluish precipitate has the composition $\text{CuCO}_3 + \text{Cu}(\text{OH})_2 + \text{H}_2\text{O}$, but on drying the water escapes, leaving $\text{CuCO}_3 + \text{Cu}(\text{OH})_2$. It has a greenish color after drying, and has been used as a pigment under the name *mineral green*. It should dissolve completely in diluted acids with a green color, and in aqua ammonias with a blue color.

CUPRI SUBACETAS.—SUBACETATE OF COPPER.

FORMULA: $(\text{C}_2\text{H}_3\text{O}_2)_2\text{Cu} \cdot \text{CuO} + 6\text{H}_2\text{O}$. **MOLECULAR WEIGHT:** 196.68.

SYNONYMS: *Cupri subacetat, Cupric subacetate, Oxy-acetate of copper, Verdigris, Ærugeo, Viride æris.*

Preparation.—Subacetate of copper, or *verdigris*, was formerly prepared chiefly in the southern parts of France. It is formed by exposing sheet copper to the action of the acetous fumes which are evolved in the process of wine-making. The refuse of the grapes placed in heaps, passes into the acetous fermentation, whereby the copper sheets are oxidized, and the oxide so formed unites with free acid. About the end of 4 or 6 weeks this is removed by scraping, and the plates are again exposed to the further action of the grape refuse. The paste-like substance which is thus formed, from time to time removed from the plates, is pounded with mallets of wood, and bagged in white leather, each bag weighing from 25 to 30 pounds. It may also be made by sprinkling vinegar over the copper.

Chemical Composition and Description.—Verdigris is an impure mixture of several basic acetates of copper. The method of preparation necessarily produces

a substance of varying composition, containing more or less of foreign substances. The principal ingredient has the formula as given above.

Commercial verdigris occurs in the form of hard lumps of irregular shapes, greenish-blue or bluish-green, often interspersed with light-green blotches, and when freshly broken is of partially crystalline structure. It is heavy and earthy. To the taste it is nauseous, styptic, and coppery, and in powdered form has a disagreeable, acetous odor. Alcohol does not dissolve it, and water partially dissolves it, at the same time decomposing it, precipitating a deep-green, insoluble, tribasic acetate, which ultimately becomes black, while the neutral acetate remains in the solution. Verdigris is speedily blackened by hydrogen sulphide; diluted sulphuric acid, with the aid of heat, almost wholly dissolves it, from which solution no precipitate is caused by ammonia; hydrochloric acid dissolves it, with the exception of about 5 per cent of impurity; concentrated sulphuric acid decomposes it, evolving acetous fumes; ammonia dissolves all but its impurities, forming an intense violet-blue solution. The so-called "verdigris" observed on copper vessels when exposed to moisture, is not an acetate of copper, but a carbonate.

Action and Medical Uses.—Detergent and escharotic. Never used internally, but occasionally employed externally by some practitioners to remove *sylphilitic verrucae*, *fungous growths*, and *callous edges*, and as an application to obstinate *ulcers*, *ringworm*, *ringworm of the scalp*, *ophthalmia tarsi*, etc. The powder may be sprinkled on the surface, or it may be used in the form of ointment. It is best employed as an escharotic when deprived of its water of crystallization by heat, which leaves an efflorescent mass. Verdigris is poisonous, and when swallowed, is decomposed by zinc and copper filings, in the dose of from $\frac{1}{2}$ to 2 drachms, followed by the free use of warm water, and afterward subduing the inflammatory symptoms by the usual means; or wheat flour, milk, and white of egg may be freely administered in water, or sugar and water, and vomiting be produced as speedily as possible.

CUPRI SULPHAS (U. S. P.)—COPPER SULPHATE.

FORMULA: $\text{CuSO}_4 + 5\text{H}_2\text{O}$. MOLECULAR WEIGHT: 248.8.

SYNONYMS: *Blue stone*, *Blue vitriol*, *Cupric sulphate*, *Cuprum vitriolatum*.

Preparation.—Sulphate of copper, or blue vitriol may be made by dissolving copper in diluted sulphuric acid, with the addition of nitric acid, evaporating and crystallizing. Metallic copper is scarcely acted upon by diluted sulphuric acid, even when warmed, but the addition of sufficient nitric acid to oxidize it causes it to readily dissolve. The nitric acid is reduced in this process, evolving vapors of nitric oxide (NO), which in contact with air, form red fumes of nitrogen peroxide (NO_2).

Description and Tests.—"Large, transparent, deep-blue, triclinic crystals, odorless, of a nauseous, metallic taste; slowly efflorescent in dry air. Soluble at 15°C . (59°F .), in about 2.6 parts of water, and in 0.5 part of boiling water; almost insoluble in alcohol. When carefully and continuously heated to 30°C . (86°F .), the salt loses 2 of its 5 molecules of water (14.43 per cent), and is converted into a pale-blue, amorphous powder. Two more molecules of water are lost at 100°C . (212°F .), while the fifth is retained until 200°C . (392°F .), is reached, when a white, anhydrous powder remains (63.9 per cent of the original weight). At a still higher temperature sulphur dioxide and oxygen are given off and a residue of black cupric oxide is left. The aqueous solution (1 in 20) has a blue color, and shows an acid reaction with litmus paper. If a drop of the solution be placed upon a bright piece of iron, it will produce a red stain of metallic copper. With potassium ferrocyanide T.S. the solution yields a deep reddish-brown precipitate. Barium chloride T.S. produces a white precipitate, insoluble in hydrochloric acid. If ammonia water be added to the solution, drop by drop, a pale-blue precipitate of cupric hydrate is formed which redissolves in an excess of ammonia water, forming a deep azure-blue solution, leaving no trace of residue undissolved (absence of iron, aluminum, etc.). If the aqueous solution (1 in 20) be heated to boiling with an excess of sodium hydrate T.S., until all of the copper has been converted into black cupric oxide, it will yield a filtrate which, after acidulation with acetic acid, should not be colored or rendered turbid by an equal

volume of hydrogen sulphide T.S. (absence of arsenic, lead, zinc, etc.). If hydrogen sulphide gas be passed through 10 Cc. of the solution slightly acidulated with hydrochloric acid, until all of the copper is precipitated as sulphide, the filtrate should, on evaporation, leave not more than a trace of residue (limit of iron, aluminum, alkaline earths, etc.)—(U. S. P.).

The *pulvis sympatheticus* of former times was the anhydrous white powder obtained by heating to about 200° C. (392 F.), while the *aqua sapphirina* was the deep-blue solution prepared by treating the pale-blue cupric sulphate with excess of ammonia. When less ammonia water is taken a green-blue precipitate of hydroxide of copper is formed, which dissolves if excess of ammonia is added, the well known deep-blue color resulting.

Action, Medical Uses, and Dosage.—Sulphate of copper in small doses is astringent and tonic; in large doses a prompt emetic. When the tissues are sound and intact it seldom acts as an escharotic. The earlier notions in regard to its toxic qualities are not now entertained, and death in fact seldom results from its employment even in large doses, though a gastro-intestinal irritation may persist for some time. Usually, however, recovery from overdoses is prompt. In small amounts copper is now deemed an important blood maker in certain anemic conditions (see *Acetate of Copper*). The emetic action of sulphate of copper is prompt and decided, and without nausea and the depression following many other agents. For *narcotic poisoning* it is quicker and just as safe an emetic as zinc sulphate, while the dose is smaller, from 3 to 5 grains. Occasionally, however, death results directly from sulphate of copper, gastro-intestinal congestion being the only discoverable post-mortem condition; when death has taken place some time after the ingestion of the salt, ulceration, sloughing, and perforation have been observed. The toxic symptoms of poisoning by this drug are: Headache, spasms, intestinal pain, vomiting, occasionally jaundice, collapse, and arrest of secretion of the urine.

In cases of poisoning by sulphate of copper, administer pure reduced iron, or iron filings, which reduce the copper in an insoluble condition, empty the stomach by means of the stomach pump or by hypodermatic injection of apomorphine, and give white of egg freely in sugared water. Treat the subsequent inflammation on general principles. Sulphate of copper is one of the many discarded remedies for *epilepsy*, and is said to be efficient, given in $\frac{1}{4}$ -grain doses 3 times a day, in *quartan agues*. However, the salt is seldom used internally except as an emetic in *narcotic poisoning* and for *pseudo-membranous croup* after the false membrane has been thoroughly detached by other means. Prof. Scudder recommended it in the same class of cases in which he employed acetate of copper (see *Cupri Acetas*). Externally it is occasionally employed as an escharotic or stimulant; and is applied by some practitioners to *indolent ulcers*, *warts*, *callous edges*, *fungous growths*, *chancres*, etc., and as a styptic to *capillary hemorrhages*, and as a wash in some cases of *chronic ophthalmia*, *gonorrhoea*, *gleet*, and *leucorrhoea*, *stomatitis*, and *malignant sore throat*, and we have found the solution of a few grains very efficient in *rhus poisoning*, promptly checking extension, though considerable smarting is produced and a faint bluish discoloration of the skin may persist for several days. For the eye, as a collyrium, 2 or 3 grains to the fluid ounce of water, will be sufficient in ordinary cases. In *granulations of the lid* and other affections of the eye, it is often desirable to use sulphate of copper in pencil form; this may be effected in two ways, viz.: 1. Mix and briskly triturate together 4 parts of the pulverized sulphate and 1 part of pulverized borax; the water of crystallization given out unites them into a plastic mass, readily molded into pencils. 2. Mix together pulverized sulphate of copper 2 parts, pulverized ordinary potash alum 1 part; gradually melt them together in a porcelain vessel, and pour the fused mass into cylindrical molds of bronze or copper, to prevent the precipitation of metallic copper; the molds should have a diameter of about $\frac{1}{4}$ of an inch. Foltz does not favor the use of this remedy in eye disorders, believing other agents are as efficient and kindlier in action. He suggests, however, that it seems indicated in the transitional stage from *acute to chronic trachoma*, with pale, indolent follicles, and in old, chronic *trachoma*, with transverse, cicatricial bands across the conjunctiva, and the granulations undergoing atrophy (Webster's *Dynam. Therap.*, 575). A 10 per cent solution is favored to destroy *fungous (thrush) growths in the ear*, and to

cauterize after removal of *tympanic cholesteatoma*. From 2 to 10 grains of the salt dissolved in a fluid ounce of water, according to the circumstances under which it is to be employed, will form a stimulating lotion. Sulphate of copper enters into *Fehling's Test Solution* for diabetic sugar. Dose as an emetic, 3 to 5 grains; internally, $\frac{1}{4}$ to $\frac{1}{2}$ grain.

Related Drug.—CURARE ALUMINATUM. *Aluminated copper, Lapis divinus*.—Fuse together in a porcelain vessel at a moderate heat, pure copper sulphate, alum, and potassium nitrate, of each, 17 parts. Add to this, stirring thoroughly, a mixture of camphor and alum, finely pulverized, 1 part each. Pour upon a slab or plate, and when cool break into pieces and preserve in well-stoppered containers.

CURARE.—WOORARI.

The poisonous preparation, Curare.

Source and History.—Curare is a frightfully poisonous extract, prepared by the savages of South America, for the purpose of poisoning the points of their arrows. It is known under various names, bearing a general resemblance, such as *woorari*, *woorara*, *curari*, *cururu*, *ourari*, *wourali*, etc. It is said to have been first brought to Europe by Sir Walter Raleigh. It was mentioned by the Fathers d'Acunja and d'Artieda, who visited the Amazon River in 1693 (*New Remedies*, 1877). In 1745, De la Condamine brought the poison to the notice of the French Academy. It was carefully described by Waterton (1812) (*Waterton's Wanderings in South America*), together with a process of preparation, as followed by the Macoushi Indians.

Regarding its origin authorities disagree, but it is known that different tribes vary the plants that enter into its composition, and thus we have little reason to doubt the conflicting statements of travelers. Waterton states that a vine called by the Macoushi Indians "Wourali," is the poisonous agent; although, according to him, they add the fangs of vipers, and plants that simply give bulk to the extract. Bancroft (1769) obtained from the Accawan Indians, a receipt for making it from native plants, under local names, and from one of these plants (*woorara*) the extract seemed to derive its name. According to a more recent authority, Dr. Jobert, the Tecuna Indians, at Calderao (Brazil), prepare curare from *Strychnos Castelnæi*, Weddell, *Cocculus toxiferus*, Weddell, *Didelphys cancrivora*, a plant belonging to the Arum family, known as "Taja," a plant of local name "Toucan's tongue," and three Piperaceæ of the genus *Artanthe*. These are extracted with water, and evaporated to an extract. According to Jobert, the *Strychnos Castelnæi* and the Taja are the most poisonous of the constituents (*New Remedies*, April, 1878, from *Bulletin de Therapeutique*). M. Planchon, in 1888 (*Jour. de Pharm. et de Chim.*, p. 539), summarizing what was known regarding the botanical origin of the various kinds of curare, states that the curare of the Amazon is derived from *Strychnos Castelnæiana*, Baillon (*S. Castelnæi*, Weddell); that of British Guiana from *Strychnos toxifera*, and that of French Guiana from *Strychnos Crevauxii* (named by Planchon). The curare of the Orinoco region, according to Gaillard's report, is of two kinds; one of weaker activity, from *Strychnos Gubleri*, used for hunting purposes, and another (strong curare) from *Strychnos toxifera*, a plant that extends over a vast territory in South America.

Description and Chemical Composition.—In appearance curare seems to differ according to its origin and its age. Sometimes it is described as a syrup, into which the points of the arrows are dipped; again, it is of a hard, resinous appearance. It is, in reality, simply a vegetable extract, and may be expected to vary as much as other extracts; and we know that time and mode of preparation will change the general appearance of all solid extracts. In quality also, it is uncertain; according to Blodgett (1878), the most active article presented a glistening fracture, and was of a dark-brown color. Doubtless, those specimens which contain the largest proportion of the extract from the species of *Strychnos*, or of *Cocculus toxiferus*, are most poisonous. Although, in 1828, Roulin and Bousin-gault announced the poisonous principle to be *curarine*, yet, for some years afterward, it was erroneously believed by many that curare depended upon strychnine and brucine for its poisonous property, for Oberdörffer had announced that *woorara*, from three sources, yielded both strychnine and brucine, and Wittstein

stated that both alkaloids are present in woorara from Brazil, and in the wood of *Strychnos toxifera*, Schomburghk. It is generally accepted, at the present day, that curare contains curarine, a very poisonous substance, resembling strychnine in some respects, but differing quite markedly in others.

Curare is of a bitter taste, soluble in cold water to the extent of about 75 per cent, which fluid also extracts the poisonous substance known as curarine. Curarine ($C_{12}H_{17}N$) (Sachs) is an alkaloid, and was discovered by Roulin and Boussingault. It is colorless or white, of a bitter taste, deliquescent to a certain extent in moist air, soluble in water, and in alcohol, less soluble in chloroform, and insoluble in pure ether, benzol, oil of turpentine, and disulphide of carbon. It has an alkaline reaction, and unites with acids to form crystallizable salts. According to Sachs, it exists naturally as a sulphate. It may be separated from strychnine, if mixed with that alkaloid, by benzin, in which substance, according to Flückiger, curarine is insoluble. According to R. Böhm (1887) curarine is yellow and neutral in reaction. Its aqueous solution is fluorescent (greenish) and when evaporated, after the addition of a mineral acid, yields non-toxic, acicular crystals. Curare when treated with water, leaves from 5 to 50 per cent of a residue; the solution contains large amounts of another alkaloid of a non-poisonous character, soluble in diluted sulphuric acid, and named by Böhm *curine*. By treatment with iodide of methyl, curine yields an alkaloidal body exhibiting the poisonous activity of curare itself. Curine is amorphous, but may be crystallized from ethereal solutions. It is little soluble in water, but easily soluble in alcohol (*Jahresber. der Pharm.*, 1887, p. 415).

Action, Medical Uses, and Dosage.—Curare, or woorara, produces its poisonous effects only when it has penetrated into the circulation, either by means of a wound, by rectal injection, or by inhalation (Pelouze and Bernard). When applied to the skin it powerfully irritates. It first paralyzes the voluntary and then the involuntary muscles, death, when it occurs, being due to respiratory paralysis. It is seldom toxic when introduced into the stomach, although it would be prudent to use some care in its internal administration, as fatal results are stated to have followed its ingestion in maximum doses, or when taken upon an empty stomach. However, saccharine urine and profuse perspiration are said to have been produced by its internal administration. The symptoms following its introduction into the circulation are muscular paralysis (which, more or less rapidly, becomes general), stupor, suspended respiration, sometimes convulsions, and death, the heart continuing to act for some time after all other indications of life have disappeared. It is stated that animals have recovered from its effects, even at this stage, artificial respiration having been resorted to before the heart had wholly ceased its action. The difference in the character, and in the rapidity of the symptoms observed in poisoning by this agent, is supposed to be due to a difference in its composition, and to its more or less rapid expulsion through the urinary organs. The causes of the phenomena produced by it are not satisfactorily determined; they have been variously attributed to paralysis of the respiratory nerve centers, and of the motor nerves; to a primary and direct action upon the heart; to a primary influence upon the nerve terminations, etc. It has no effect upon the pulse or physical temperature, and no perceptible change has been observed in the character of the blood nor in that of the solid textures; hence it can not be a blood poison.

Vella (*Pharm. Jour.*, 2d series, Vol. II), in 1861, decided that strychnine and the poisonous principle of curare, antidoted each other, basing his assertions upon actual experiments, in which large doses of both substances were administered to dogs without fatal effect, while afterward the same amount of strychnine alone, resulted in death, but caution must certainly be observed in the use of so powerful a poison, even in the way of an antidote. In the *N. Y. Med. Gaz.*, July, 1855, Drs. Brainard and Green announced that a solution of iodine 1 part, iodide of potassium 2 parts, and water 48 parts, acts as an antidote to the poison when the antidote is injected under the skin, and neutralizes it when mixed with its solution. Extreme care must be employed both in handling and administering so deadly a substance. It should by no means be permitted to come into contact with a cut, abrasion, or scratch; indeed, it were safer never to handle it with the naked fingers; neither should we attempt to pulverize the dry article, as its inhalation

is dangerous. Mr. H. S. Wellcome exhibited, at the meeting of the American Pharmaceutical Association, held in Indianapolis, Ind., 1879, arrows brought by himself from South America and poisoned by the Indians with curare. These arrows had been dipped into a *paste* (soft extract), about $\frac{1}{4}$ an inch of each point being covered with the poisonous extract. Mr. Wellcome informed Prof. Lloyd that the natives could antidote the poison if treatment was instituted at once, but that they refused to name the antidote.

The therapeutical employment of curare has been suggested in certain severe and obstinate spasmodic affections, as in *epilepsy*, *chorea*, *hydrophobia*, and, more particularly, in *tetanus*. It is used by subcutaneous injections of its filtered aqueous solution, thus: Add curare 1 grain, to distilled water 24 minims; dissolve, let the solution stand 48 hours, and filter; of this, from 2 minims ($\frac{1}{12}$ grain) to 6 minims ($\frac{1}{2}$ grain) may be used at one injection, carefully repeating the injections until relaxation of the muscles has been effected. Curarine, dissolved in water, with a few drops of sulphuric acid added, to facilitate its solution, is to be used in still smaller doses—from the $\frac{1}{12}$ to the $\frac{1}{16}$ part of a grain. It is doubtful whether this agent will ever come into general use as a medicinal remedy; at least, not so long as other medicines are known in which greater confidence can be placed. The diversity of action, attributable, in some instances, to its difference of composition, in others to its inertness, or to its highly active qualities, render it an uncertain, as well as an unsafe, remedy.

Related Substances.—*Musculus venenosus*, *Muscul.*—Owing to the presence probably of certain ptomaines, some mussels are poisonous, or, at least, edible mussels may become occasionally toxic, as, when kept in filthy water, abounding in amoeba, bacteria, etc. Brieger has shown that one of these animal bases (*mytilotoxine*, $C_8H_{15}NO_2$) has physiological actions similar to curare. Mussels are rendered non-toxic by being boiled in weak alkaline solutions. (For an interesting account of this subject, see Vaughan and Novy's *Ptomaines*, etc., 1896).

Malouetia nitida, *Guachamacil*.—A Venezuelan plant containing *guachamacine*, an alkaloid identical, according to Kobert, with *curarine* (*A. J. P.*, 1885).

CHINOTOXINS, or *Dichinolindimethylsulphate*.—A new synthetic product is reputed to act like curare.

CURCAS PURGANS.—PURGING-NUT.

The seeds of *Curcas purgans*, Adanson (*Jatropha Curcas*, Linné).

Nat. Ord.—Euphorbiaceæ.

COMMON NAMES: *Purging-nut*, *Physic-nut*, *Barbaoloes-nut*.

Botanical Source.—A large shrub, with a milky juice, and leaves that are heart-shaped, smooth, 5-lobed, and borne on leaf-stalks 2 or 3 inches long. The flowers are small, green, monocious and in axillary, stalked cymes. The corolla and calyx are 5-parted, and the male flowers have 10 stamens. The ovary is 3-lobed, 3-celled, and has a 3-parted style. The fruit is a fleshy black berry, and contains 3 seeds, about an inch in length. The kernel is oily, inodorous, sweetish to the taste, followed by acidity.

History.—This is a large, thick-stemmed, lactiferous shrub, a native of the Cape de Verd Islands (Pickering), but cultivated as a hedge plant, as well as for its oil, and has also been naturalized in the West Indies, South America, and in most parts of the tropics. The plant was formerly referred to *Jatropha*, from which it differs in having a monopetalous corolla. The seeds are called *Purging-nuts*, *Nuces cathartice Americanæ*, *Semina ricini majoris*, *Semen curcadis*, *Ficus infernalis*, *Nuces Barbadosæ*, *Physic-nut*, etc., (*New Remedies*, 1878, from *Zeitschrift des Oesterr. Apoth. Vereins*), and affords an oil, upon pressure, which is a drastic cathartic, and which has been used to adulterate croton oil.

Description.—The seeds are about 1 inch long, oval, flattish on one surface, rounded on the opposite, each side presenting a slight elevation, running lengthwise. It has a fissured testa of a blackish color. Taste at first sweet, afterward acid. It has no odor and contains oil.

Chemical Composition.—The oil was examined by M. J. Bouis (1854) (*Comptes Rendus*, Vol. XXXIX) who obtained it from the nuts, by pressure, to the amount of 37 per cent. It is white, has a density of 0.910 at 16.5° C. (62° F.), is almost insoluble in alcohol, easily saponified by soda, forming a white, hard soap. It is decomposed by heat, yielding, among other products, sebacic acid. When saponi-

fied by potash, if the resulting soap is decomposed by hydrochloric acid, a mixture of fatty acids is produced, from which, by pressure, from 18 to 20 per cent of a white, solid acid may be separated. This is soluble in hot alcohol, from which, on cooling, it is deposited in brilliant spangles. From its close resemblance to cetic acid (from spermaceti), Bouis named it *isocetic acid*. August Siegel, of Dorpat, who more recently (1893) investigated the seeds of *Curcas purgans*, found isocetic acid to be a mixture of palmitic and myristic acids, and isolated a peculiar fatty acid of the formula $C_{15}H_{31}O_2$, which he called *curcinoleic acid*. Besides, he obtained from the seeds, previously deprived of their fatty oil, a toxic albuminoid substance, soluble in water and resembling the poisonous principle of *Amanita phalloides*. It was named *curcin*, and becomes inert when exposed to temperatures above $50^{\circ} C.$ ($122^{\circ} F.$), or when treated with precipitants. The percentage composition of the seeds was found by Siegel as follows: Water, 7.2; ash, 10.2; oil, 33.86; sugar, coloring matter, cellulose, 47.83; albuminoids, 1.71 (*Amer. Jour. Pharm.*, 1893).

Action, Medical Uses, and Dosage.—The seeds of Purgine or Barbadoes-nut occasion emetic and drastic cathartic effects, accompanied with a burning sensation in the fauces and stomach, and other unpleasant, and even serious, symptoms. However, if the seeds be entirely deprived of their embryo, the emesis and other disagreeable sensations do not occur. The juice of the leaves acts as a rubefacient, and has been successfully employed, in the countries where the shrub grows, as a local application in *rheumatic pains*, in certain *eruptive affections*, and in *piles*. The oil, in the dose of 10 or 12 minims, is a cathartic, somewhat resembling croton oil in its action, though less severe. It may be used in all cases where the employment of croton oil is indicated.

Related Species.—*Curcas multifidus*, Endlicher (*Jatropha multifida*, Linné). South America. The seeds resemble somewhat the Barbadoes nut and yield an oil probably identical with that from the seeds of *Curcas purgans*.

Anda Gomezi, Jussieu (*Joannesia principis*, Vellozo; *Anda brasiliensis*, Raddi). The *Anda* tree of Brazil, yielding purgative brown, chestnut-like seeds, having the taste of peach-kernels. The seeds act violently as a purgative, and may even act as an emeto-cathartic. The reddish, limpid oil, of which the seeds yield about 50 per cent, is also actively cathartic. By preparing the seeds in emulsion, the germ and testa being first removed, a griping constituent is avoided, and the oil may be used in the place of castor oil, the action of which it closely resembles. Doses of $\frac{3}{4}$ to $\frac{3}{2}$ act gently and efficiently. Large doses harshly overact.

Jatropha macrocarpa. *Joama* (Euphorbiaceæ).—Northern Mexico and Texas. An active purgative in overdoses; a mild evacuant and cholagogue in doses of $\frac{1}{2}$ drachm to 2 fluid drachms of the fluid extract.

CURCUMA.—TURMERIC.

The rhizome of *Curcuma longa*, Linné (*Curcuma rotunda*, Linné; *Amomum Curcuma*, Jacquin).

Nat. Ord.—Zingiberaceæ.

COMMON NAMES: *Turmeric* (long and round), *Curcuma*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 269.

Botanical Source.—This is a perennial plant, with the roots or tubers oblong, palmate, and deep-orange inside. The root-leaves are about 2 feet long, lanceolate, long-petioled, tapering at each end, smooth, and of a uniform green color. The petioles are sheathing. The spike is erect, central, oblong, and green. Its flowers are dull yellow, arranged 3 or 5 together, surrounded by bracteolæ (L.).

History.—Turmeric is indigenous to several parts of southern and eastern Asia, and is extensively cultivated in China, Hindustan, and other countries, where it is propagated from cuttings of the root. Several varieties are found in commerce, their names being derived from the countries producing them. Thus we have *Chinese*, *Madras*, *Bengal*, *Java*, and *Cochin turmeric*s. The latter is thought to be derived from another species than *Curcuma longa*, Linné, and though never

Fig. 90.

Long turmeric.

Short turmeric.

used as turmeric in Cochin, the natives obtain from it a variety of aniseed. The other varieties differ somewhat, though in general not enough to be noted by inexperienced persons. The Chinese turmeric is generally preferred. The turmeric is the least valuable, and is the product of *Curcuma longa*, *Curcuma* Haaskarl. Curcuma is chiefly used as a condiment and for dyeing; the latter variety, which is of a deeper color, being generally preferred for the latter purpose. While the foregoing varieties of curcuma are recognized, the drug is generally distinguished in commerce by the terms *long* and *round turmeric*. The latter is the central or primary rhizome of the plant, while the former consists of the lateral or secondary rhizomes. Turmeric is largely used in the preparation of *Turmeric Test Paper*, and also for coloring table mustard and some other food products.

Description.—*Long turmeric (curcuma longa)*, when dry, is in slightly conical, subcylindrical, or oblong tubers, about 1 to 3 inches in length, and from $\frac{1}{2}$ to 1 inch in diameter, often pointed or tapering at one end, yellowish externally, with transverse, parallel rings, internally deep-yellow or reddish-brown, marked with shining points (due to immersion in scalding water in order to facilitate the drying process), dense, solid, having a short, granular fracture, and forming a yellow powder. *Round turmeric (curcuma rotunda)*, differs in being ovate-shaped, or subspherical, occasionally pointed and crowned with leaf remains at the upper end. They are from $1\frac{1}{2}$ to 2 inches long, and from $\frac{3}{4}$ to $1\frac{1}{2}$ inches in diameter. Turmeric has a peculiar, somewhat fragrant odor, and a bitter, slightly acid taste, like that of ginger, exciting a moderate degree of warmth in the mouth, and communicates a yellow color to the saliva. It yields its properties to water or alcohol.

Chemical Composition.—The yellow coloring matter, *curcumin*, was first obtained (impure) by Vogel and Pelletier; more recently it was prepared in a crystalline form by Daube (1870), and contemporaneously by Ivanow and S. sky. It was further studied and some derivatives of it prepared by C. L. Jackson and A. G. Menke, in 1882-83, who determined the formula $C_{21}H_{20}O_6$. These chemists obtained it from the root by first removing the fatty and resinous oil by means of ligroin, which removed 11 per cent of the weight of the root, then abstracting curcumin (contaminated with resins), by means of ether, and finally crystallizing from alcohol until the melting point became constant at $178^{\circ} \text{C. (352.4}^{\circ} \text{F.)}$. The yield was 0.3 per cent. As thus obtained, curcumin crystallizes in amber-yellow prisms, appearing orange-yellow in reflected light, soluble in water and diluted acids, sparingly soluble (1 in 2000) in benzene, a poor solvent, which refuses to dissolve the resins; easily soluble in ether, chloroform, and alcohol; also in diluted alkaline solutions with a striking red-brown, deep orange color. It is partly soluble, with crimson color, in concentrated acid solutions. Non-alkaline solutions exhibit green fluorescence. Chemically, curcumin is a substituted aromatic oxyacid, yielding *vanillin* with weak oxidizers, and *catechuic acid* when fused with caustic potash.

Filtering paper saturated with an alcoholic solution of curcumin and dried reacts like *turmeric tincture* (see below) towards acids, alkalies, and boric acid. It turns red-brown with alkalies which color becomes violet upon drying; the color is restored with acids. When the paper is dipped into solution of boric acid it turns orange-red (upon drying), and remains so even when it is afterward washed with free mineral acid. Paper that has been turned to orange by boric acid will assume a blue color when it is moistened with diluted alkali. Schlumberger (1866) obtained crystalline *rosocyanin* by heating an alcoholic solution of curcumin and boric acid with mineral acids and then allowing the blood-red solution to cool. It is insoluble in water, but soluble in alcohol, this solution turning blue upon the addition of an alkali.

A red compound of curcumin with boric acid was obtained in the form of a precipitate by the same author, by adding water to a mixture of alcoholic curcumin and boric acid; boiling water removed therefrom all the boric acid, leaving a yellow resin which he called *pseudo-curcumin*. Strong sulphuric acid forms with curcumin a solution of crimson color, which color disappears upon dilution with water, a precipitate of yellow flakes resulting.

About 1 per cent of an acid volatile oil is present in curcuma root, one constituent of which, called *turmerol*, was isolated, in 1883, by C. L. Jackson.

A. G. Menke, the boiling point being about 193° C. (379.4° F.). It has a pleasant aromatic odor, is lighter than water, and is oxidized by means of potassium permanganate to *terephthalic acid* ($C_6H_4[COOH]_2$). The presence of alkaloids in curcuma root was indicated by Ivanow-Gajewsky and by J. Cook. Kachler, in 1870, obtained considerable amounts of acid potassium oxalate from an aqueous infusion of the root.

TURMERIC TINCTURE and TURMERIC PAPER.—Turmeric is much employed as a test for alkalies, which render it reddish or brownish; white bibulous paper or paper not sized, is brushed over with the tincture or decoction, or dipped into one of them, and dried in a neutral atmosphere (see *Reagents and Test Solutions of U. S. P.*, No. 59).

Action, Medical Uses, and Dosage.—Turmeric is a mild, aromatic stimulant, but is seldom used in this country, except to color ointments and pharmaceutical mixtures.

Related Product.—*Murraya Koenigii* (Nat. Ord.—Rutaceæ), *Curry leaves*. The leaves of this tree, which grows wild in the mountains of the western coast of India, are quite extensively used as a condiment. They enter into the mixture known as *Curry powder*, largely used in pickling and cooking. In India the leaves are regarded as tonic and stomachic, and are given raw in *dysentery* and applied externally in *skin eruptions*. The Hindus employ an infusion of the leaves to check *vomiting* (Ainslie). The root is stimulant, and is in repute as a remedy for the *bites of venomous animals* (Dymock, *Mat. Med. of Western India*). An essential oil, two resins, and a bitter glucosid, *koenigin*, were obtained from the leaves. *Simabolee* oil is obtained from the seeds. The white, sweet-odored flowers of *Murraya exotica* (cultivated), yielded (De Vrij) the glucosid *murrayin*, ($C_{25}H_{32}O_{10}$) (Dymock).

CUSO (U. S. P.)—KOUSO.

"The female inflorescence of *Hagenia abyssinica* (Bruce), Gmelin"—(*U. S. P.*). (*Brayera anthelmintica*, Kunth; *Banksia abyssinica*, Bruce).

Nat. Ord.—Rosaceæ.

COMMON NAMES: *Kosso*, *Cusso*, *Kouso*, *Kusso*, *Kosso*, *Cosso*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 102.

Botanical Source.—This is a tree growing about 20 feet high, with round, rusty, tomentose-villose branches, marked by the annular cicatrices of the fallen leaves. The leaves are crowded, alternate, interruptedly imparipinnate, and sheathing at the base. The leaflets are oblong, or elliptical-lanceolate, acute, serrate, villose at the margin and on the nerves of the under surface. The stipules are adnate to the petiole, which is dilated at the base, and amplexicaul. The flowers are dioecious, small, greenish, becoming purple; repeatedly dichotomous; and with pedicels with an ovate bract at the base. The so-called male flowers may be regarded as hermaphrodite flowers, inasmuch as the carpels are well developed. Female flowers somewhat different in their structure. The outer segments of the calyx are much more developed than in the female flowers, are 4 or 5 times larger than those of the inner row, and placed somewhat below them; the petals are entirely wanting; the stamens are rudimentary and sterile. The ripe fruits are unknown (Kunth).

History.—This plant was introduced into notice by a pharmacist of Paris, and its properties as an anthelmintic were investigated by the Academy of Medicine and the Academy of Sciences as early as 1847. It grows in Abyssinia, the flowers being the parts of the plant used. They are reduced to a fine powder, which is brownish, like jalap, bitter, somewhat nauseous, and possessed of an odor similar to scammony. The flowers, not powdered, have a somewhat fragrant odor, and a slight taste, which soon becomes nauseous and acrid. The plant was named in honor of Dr. Brayer, who first made its virtues known in Europe. Bruce, in his *Travels*, Vol. VII, appendix, gives a minute description of the plant, and calls it, in testimony of esteem for a friend, "*Banksia abyssinica*." Dr. Kirk, in the appendix to the second volume of the "*Highlands of Ethiopia*," by Sir W. C. Harris, calls it "*Hagenia abyssinica*," and states "that a cold infusion of the dried flowers and capsules, constitutes the famous drasticum purgans and anthelminticum of the Abyssinians." Both the male and female inflorescence are collected, though the latter only are official in the *U. S. P.* The dried male flowers are of a pale, greenish-brown hue, and are frequently termed *kosso-cells*. The com-

mercial female flowers are of a light, brown-red color, and are known as *red kouso*. The inflorescence is collected before the ripening of the fruit, forming loose, dried panicles, which, as found in commerce, are often considerably broken.

Description.—The *U. S. P.* thus describes the official *cusso*: "In bundles, rolls, or compressed clusters, consisting of panicles about 25 Cm. (10 inches) long, with a sheathing bract at the base of each branch; the two roundish bracts at the base of each flower, and the 4 or 5 obovate, outer sepals are of a reddish color, membranous and veiny; calyx top-shaped, hairy, enclosing 2 carpels or nutlets; odor slight, fragrant and tea-like; taste bitter, acrid, and nauseous"—(*U. S. P.*).

Chemical Composition.—Wittstein found the flowers to contain gum, wax, bitter acrid resin, sugar, tasteless resin, fatty matter, chlorophyll, tannin, and lignin. The first-named resin is identical with *koussin*.

A preparation named *koussin* was made by M. Pavesi and M. Vée, according to the following process: Treat *kouso* (300 parts) with alcohol (100 parts), and calcium hydrate (25 parts), at a temperature of 60° to 65.5° C. (140° to 150° F.). Also digest the residue with barley water (600 parts). Mix the solutions thus obtained, filter, and precipitate by means of acetic acid. The *koussin* thus obtained is yellow, bitter, resinous, non-crystallizable, and insoluble in cold alcohol. Merck obtained it in well-defined rhombic crystals of sulphur-yellow color, readily dissolving in chloroform, ether, carbon disulphide, and benzol; less soluble in glacial acetic acid, and alcohol of specific gravity 0.818, and not at all soluble in water. Flückiger (*Pharmacognosie*, 1891) states that *koussin* crystallizes best on cooling its solution in concentrated sulphuric acid, saturated at 15° C. (59° F.). It is dissolved by alkalis, while acids reprecipitate it, unaltered, as an amorphous, white mass, which may be again obtained in crystals from solution in hot alcohol. *Koussin* is not chemically altered by cautiously melting it; in this condition it remains as a yellow, amorphous, transparent mass, which, if simply touched with a minute portion of alcohol, instantly assumes the form of stellate, crystalline tufts. When treated with concentrated sulphuric acid, if water is added to the solution, amorphous white *koussin* is precipitated. If the (yellowish) solution of *koussin* in concentrated sulphuric acid is allowed to stand for a few days, or if it be carefully warmed, a scarlet-red coloration makes its appearance, *isobutyric acid*, but not sulphurous acid, being formed as a by-product. On diluting the red solution with water, purple-red amorphous flakes are precipitated. These vary in composition from $C_{21}H_{21}O_{10}$ to $C_{23}H_{21}O_{10}$. Flückiger and Buri assign to Merck's *koussin* the composition $C_{21}H_{21}O_{10}$ (*Pharmacognosie*, 1891). This principle has been variously termed *kousin*, *kosin*, *kooscin*, *brayerin*, and *tæniin*. It is notable that the pure *kousin* is not so active an anthelmintic as the amorphous product obtained by Pavesi's method.

Action, Medical Uses, and Dosage.—Purgative and anthelmintic. Used by the Abyssinians for *tapeworm*, to which they are very subject, and it is said they will not travel without having some of the *kouso* with them. The dose of the flowers in powder is a small handful, or about 4½ drachms, which is to be macerated in about 3 gills of lukewarm water for 15 minutes. The infusion, with the powder suspended in it, is taken either in 1, 2, or 3 doses, quickly following each other. It is recommended that lemon-juice, or tamarind water, should be taken freely before and after the *kouso*. The patient must be prepared by a low diet for 1 or 2 days previously, and by a dose of castor oil, or other purgative, and the *kouso* is to be taken on an empty stomach early in the day. The clear infusion has the color, and a somewhat similar taste, of very weak senna tea. Its operation is safe, speedy and most effectual, rarely causing any annoyance or uneasiness, except a slight nausea, and this but seldom; occasionally emesis takes place, or diuresis. A gentle cathartic after its operation is also advisable. As far as it has been used, when fresh, it has not failed to kill and expel the worm.

CYCLAMEN.—CYCLAMEN.

The tuber of *Cyclamen hedersefolium*, Willdenow (*Cyclamen europæum*, Miller). *Nat. Ord.*—Primulacæ.

COMMON NAMES: *Sow-bread*, *Hog's-bread*.

ILLUSTRATION: *Botanical Magazine*, Plate 1001.

Botanical Source and History.—*Cyclamen hederæfolium* is a native of Italy and Sicily, and is occasionally found naturalized in the wet, clayey soil of England. The leaves are all radical, on slender leaf-stalks; they are heart-shaped, finely-toothed on the margin, and variegated with light and dark-green color. The flowers are solitary and nodding, on long, slender stalks; they closely resemble the flowers of the American cowslip (*Dodecatheon Meadia*). The corolla is monopetalous, with a very short tube, and a large, reflexed, 5-parted limb, which gives the flower an odd appearance. The fruit is a many-seeded, 5-valved capsule. After flowering, the slender flower-stalk twists into a spiral curl, and, bending over, ripens the seed vessel on the surface of the ground. On account of the graceful little flowers, this and other species of *Cyclamen*, are often found in cultivation. The tubers of *C. europæum*, Linné, and of *C. persicum*, Miller, are also used, and the various species have been employed in medicine from an early period. Pliny and Dioscorides advised the root as a curative agent in numerous affections. It occupied a place in the *Pharmacopœia Londonsensis* (1653), under the name *Artanitzæ cyclaminis*, and in Lewis' *Materia Medica* (1761), as *Arthanita*. It was official in Germany about 120 years ago.

Description and Chemical Composition.—The green root is an orbicular, flattened tuber, brown externally, white within, with blackish radicles. It contains about 80 per cent of moisture, and $\frac{1}{2}$ per cent of ash. The constituents are saccharine matter, starch, gum, and *cyclamin* (M. de Luca), which is the poisonous principle of the tuber. *Cyclamin* was first obtained by Saladin, and named by him *arthanutin*. To prepare it, exhaust the dried and powdered tubers with alcohol; filter this tincture, evaporate to dryness, extract the residue with alcohol; and then permit the solution, after filtration, to evaporate spontaneously in a cool, dark place. Whitish amorphous aggregations of *cyclamin* will be deposited, which may be purified by re-solution in hot alcohol, and subsequent evaporation over sulphuric acid (*Comptes Rendus*, 1857).

As obtained by M. de Luca, *cyclamin* ($C_{18}H_{25}O_{10}$), is white, amorphous, opaque, inodorous, friable, neutral, and of an acrid taste. It absorbs moisture in damp air, becomes gelatinous in a small quantity of cold water, and dissolves in 500 parts of this fluid, rendering the liquid frothy, like soap-suds. In aqueous solution, it is coagulated by a temperature of from 60° to 77° C. (140° to 170° F.), but the coagulated matter redissolves after a few days. It readily dissolves in hot alcohol, acetic acid, wood spirit, and glycerin, but is insoluble in chloroform, ether, oils, and disulphide of carbon; tannin precipitates it from its solutions. By the action of boiling diluted acids, glucose is formed, and a body called *cyclamiretin* ($C_{18}H_{27}O_2$); hence it is a glucosid. For further details regarding these substances, see Husemann and Hilger (*Pflanzenstoffe*). Both *cyclamin* and the juice of the tuber are poisonous to man and fish, but the tubers are sought for and eaten by hogs with impunity, thus giving rise to the vulgar names applied to the plant—"sow-bread," or "hog's-bread." *Cyclamin*, the chief active principle of this plant, has not been employed therapeutically; administered to small animals, it has occasioned their death in a few days. Its action has, by Bernard, been compared to curarine; and to saponin, senegin and smilacin, by Schroff.

Action, Medical Uses, and Dosage.—The root or tuber of *cyclamen*, in its recent state, is a drastic cathartic, for which purpose it has been long in use among the peasantry of some parts of Europe. Its effects, however, are frequently very severe, as violent emesis, hypercatharsis, intestinal inflammation, cold sweats, *tinnitus aurium*, spasmodic movements, etc., which sometimes result in death. This severity of action is lessened by drying the tubers. In the dried state, 8 or 10 grains of the powder, rubbed up with an equal quantity of starch or gum, will have a purgative effect. Formerly, an ointment was prepared from the fresh tubers, "ointment of arthanita," which was rubbed upon and around the umbilicus of children, for the expulsion of worms, upon the abdomen of adults to cause emesis, and upon the region over the bladder to increase the urinary discharge. The fresh tubers, bruised and formed into a cataplasm, have been employed as a local stimulating application to indolent scrofulous swellings, abscesses, etc.

Fig. 91.

*Cyclamen europæum*.

Prof. Scudder (*Spec. Med.*) states that the tincture is prepared from the tuber in early spring, or during the period of rest of the plant. He suggests a tincture to be made from the tubers of hot-house plants. The special uses to be made of this tincture are to arrest severe *emesis*, particularly that depending upon brain disease, vertigo, tendency to fainting, inability to walk straight, and *diarrhœa*, with *tenesmus*. Tincture of cyclamen (3viii to alcohol Oj) gtt. v to aqua f3iv; teaspoonful every hour. Dose of powder, 5 grains; of decoction (3i to 3iii, in aqua Oj), 1 to 4 fluid drachms.

CYDONIUM.—QUINCE-SEED.

The seeds of *Cydonia vulgaris*, Persoon (*Cydonia europæa*, Savi; *Sorbus Cydonia*, Crantz; *Pyrus Cydonia*, Linné).

Nat. Ord.—Rosaceæ.

COMMON NAME: Quince-seed.

ILLUSTRATIONS: Köhler's *Medizinal Pflanzen*, Vol. I, Plate 34; Bentley and Trimen, *Med. Plants*, 106.

Botanical Source.—This is a well-known shrub or tree, from 8 to 20 feet high. The leaves are oblong-ovate, obtuse at base, acute at apex, entire, smooth above, and tomentose beneath. The flowers are solitary, white with a purple tinge, large, and terminal. The pome or fruit is tomentose, obovoid, yellow when ripe, having a peculiar fragrance, and an austere, acidulous, astringent taste; cells 5; seeds many, in a thick, soluble mucus (W.—L.).

History.—The quince tree is a native of Candia, but is cultivated extensively in this country and Europe, and its fruit is much employed in making jellies, preserves, etc. It grows wild in the forests north of Persia, not far from the Caspian Sea, and south of Caucasus, and also in Anatolia (De Candolle, *Origin of Cultivated Plants*, 1882). De Candolle also states that the fruit has been but little modified by cultivation, being as harsh and acrid yet as when known to the ancient Greeks. The parts used in medicine are the seeds.

Description and Chemical Composition.—The seeds are ovate, acute, flat on one side, convex on the other, being compressed triangularly, brown externally, with a reddish tinge, internally white, odorless, and of a bland, mucilaginous taste when whole, but when the testa is removed from the dicotyledonous embryo, the taste of the latter is somewhat like that of bitter almonds. The external coat of the seeds is composed of very fine cells, in which is lodged a large quantity of mucilage, which is taken up by cold or hot water. The decoction, evaporated to dryness, and powdered, will form a proper mucilage with water, in the proportion of 3 grains to the fluid ounce. One part of it gives a semi-syrupy consistence to 1000 parts of water. Pereira proposed to call this mucilage *cydonin*; he considered it a peculiar variety of gum, which, like arabin, being soluble in cold or boiling water, is different from cerasin and bassorin. This mucilage gelatinizes with perchloride of iron, but, unlike that principle, it is not affected by silicate of potassium. It has but little adhesive qualities, contains albumen and calcium compounds, is precipitated by alcohol, mercuric chloride, zinc chloride, neutral and basic acetate of lead, but is unaffected by sodium biborate in solution. Its composition is $C_{14}H_{20}O_{14}$ (Kirchner and Tollens, 1875), and it may be obtained in a dry state to the extent of 20 per cent. Oxalic acid may be derived from it by treatment with nitric acid. The cotyledons contain fixed oil, and malic acid is present in the fruit to the extent of 3 to 3.5 per cent. Sixty grains of quince seeds will make a thick mucilage in 30 minutes, of 8 fluid ounces of water.

Action, Medical Uses, and Dosage.—Decoction of quince seeds forms a demulcent mucilage, very useful in *gonorrhœa*, *dysentery*, *aphthous affections*, and *excoriations* of the mouth and fauces; also as a collyrium in *conjunctival ophthalmia*. A syrup prepared from the fruit, or the jelly, forms an agreeable article, either alone or added to drinks, for patients laboring under *febrile diseases*, *diarrhœa*, *dysentery*, and *nausea*. The following preparation rubbed upon the parts twice daily, has been recommended to discuss slow *inflammatory deposits* and *tumors*. R Quince seed 3iv, alcohol f3viij. Macerate 20 days and express. Mix with an equal bulk of turpentine (Scudder, *Spec. Med.*, 122). The mucilage should always be freshly prepared, as it sours readily.

Related Species.—*Cydonia japonica*, Persoon (*Pyrus japonica*, Thunberg); *Japan quince*. This beautiful shrub, cultivated for ornamental effect, has handsome crimson or fire-red flowers, an acidulous fruit possessing a somewhat spicy fragrance, and smooth, shining, coriaceous, serrated, ovate-lanceolate leaves, acute at each extremity. Properties probably similar to those of the preceding plant. It is a native of Japan, and blooms in April and May.

CYNARA.—GARDEN ARTICHOKE.

The leaves of *Cynara Scolymus*, Linné (*Cynara Cardunculus*, var. *sativa*, Moris).
Nat. Ord.—Compositæ.

COMMON NAMES: *Artichoke*, *Garden artichoke*.

Botanical Source.—This plant is perennial, with subspinescent, pinnate, and undivided leaves. The heads are discoid and homogamous; the involucre dilated and imbricate; the scales ovate, with fleshy bases, emarginate and pointed; the receptacle setaceous; the pappus plumose and sessile; and the achenia not beaked (W.).

History.—This well-known plant is a native of southern or Mediterranean Europe, and is cultivated in this country. The flowers, or *heads*, as they are commonly called, appear in August and September, and are the parts used; the succulent receptacle and part of the calyx-leaflets are the edible portions. In their young state, the heads, prepared with vinegar, salt, etc., are much valued by some persons. The corollas are used for coagulating milk. The juice of the leaves is amarous. This plant must not be confounded with the *Helianthus tuberosus* or *Jerusalem artichoke*, a species of sunflower, the tuberous roots of which are sometimes used as a substitute for potatoes, and as feed for hogs.

Action, Medical Uses, and Dosage.—Diuretic and alterative. Reputed very beneficial in *dropsies*, and has been efficient in *rheumatism*, *gout*, *jaundice*, *tic-douloureux*, etc. The recent leaves only should be used in the form of an extract, or alcoholic solution. Dose of the tincture, 30 to 60 drops, repeated 3 times a day; of the extract, 3 to 6 grains (Dr. Badely, in *London Lancet*, 1843, p. 556).

Related Species.—*Cynara Cardunculus*, Linné; *Cardoon*. Native of Mediterranean Europe. Used as a food similarly to the above species. The Romans ate the flower receptacle under the name *girello*, as do also the Italians. It has been naturalized over a large extent of the Pampas of Buenos Ayres, and in Chili, and is now so plentiful as to be a hindrance to travelers (A. De Candolle, *Origin of Cultivated Plants*, 1882).

CYNOGLOSSUM.—HOUND'S TONGUE.

The leaves and root of *Cynoglossum officinale*, Linné.

Nat. Ord.—Boraginaceæ.

COMMON NAME: *Hound's tongue*.

Botanical Source.—This is a biennial plant, with an erect, silky-pubescent stem, growing from 1 to 2 feet in height. The leaves are hoary, with soft down on both sides, lanceolate, acute, and entire—radical ones alternate at the base, petiolate; cauline ones sessile, clasping, with rounded or slightly heart-shaped bases. The flowers are in terminal, panicle clusters, recurved at the end; the calyx downy and 5-parted; the corolla reddish-purple, short, funnel-form, and vaulted; the throat or orifice closed by 5 converging, convex scales. Stamens shorter than the corolla. Achenia depressed, fixed laterally to the style; seeds rough, with hooked prickles (W.—G.).

History.—This plant is met with in Europe and this country, growing in waste grounds and road-sides; its name is derived from the peculiar form of the leaf; it bears purple flowers in June and July. The root is preferred to the leaves; it has a heavy, mouse-like, unpleasant odor, which is removed by desiccation, and a mawkish, amarous taste. The fresh plant is much more active than the dried.

Chemical Composition.—Prof. Schlagdenhauffen and E. Reeb, in 1892 (see *Amer. Jour. Pharm.*), found the constituents of roots, stems, leaves, and seeds of *Cynoglossum officinale* identical with those of *Heliotropium europæum*. The roots yielded by extraction with hot petroleum ether a red coloring matter identical

with that from *alkanna*. An alkaloid, *cynoglossine*, was found to exist in the alcoholic extracts of the roots and the seeds of both plants, but not in the stems or the leaves. The authors could not establish for it any curarine-like physiological properties, as claimed by others.

Action, Medical Uses, and Dosage.—Anodyne, demulcent, and astringent, and has been used in *coughs*, *catarrhs*, *hemoptysis*, *diarrhoea*, and *dysentery*. Externally, in the form of a poultice, it has been found highly beneficial in *scrofulous tumors*, *burns*, *gout*, and may be applied to recent *contusions* or *inflammations* with much advantage; also to remove the pain and soreness attending *irritated*, *bruised*, or *chafed parts*, giving complete and immediate relief, especially in *excoriation of the feet* from much traveling. The tincture, or the application of bruised fresh leaves will remove the swelling and *erythema* consequent upon severe *blows* or *bruises*. Paralyzing effects are said to be produced by it in the vertebrate animals.

Related Species.—*Cynoglossum amplexicaule* or *Wild comfrey*, affords a root which may be substituted for the official comfrey.

Cynoglossum Morisonii, De Candolle, called *Virginia mouse-ear*, *Beggar's-lice*, and *Dysentery-weed*, has been variously classed by botanists, as *Rochelia virginiana*, *Myosotis virginica*, and *Echinosperrum virginicum*. It is an annual plant, with an erect, hairy, furrowed, very broadly branched and leafy stem, from 2 to 4 feet in height. Leaves from 3 to 4 inches long, oblong-lanceolate, acuminate, entire, remote, tapering at the base, thin, minutely downy underneath, scabrous above, lower ones petioled. Branches slender and remote, each terminating in a centrifugal, divaricate, dichotomous, hairy, paniculate raceme, leafy-bracted at the base. Flowers very small, white or pale-blue; pedicels nodding in fruit. Fruit convex, densely covered with prickles having barbed points. This plant is common throughout the United States, growing in rocky grounds and among rubbish, flowering in July (W.). The whole plant has an unpleasant odor. The root is the part used, and imparts its virtues to water. It is mucilaginous, tonic, and astringent, and has been found very efficient in *diarrhoea* and *dysentery*. From its excellent effect in these diseases, it has acquired the popular name of *dysentery-root*. It has also been used with marked advantage in *cholera infantum*, *gastro-intestinal irritation of continued fever*, and as a mild tonic during convalescence from acute disease. As a diuretic, it has been useful in *cystitis*, *nephritis*, and other diseases of the urinary organs. The root may be chewed, or given in powder or infusion *ad libitum*. It will probably be found useful in other diseases, where such a combination of properties is indicated.

Echium vulgare, Linné; *Viper's bugloss*, *Blue-weed*.—Europe, naturalized in the United States, where, in the eastern and middle states, it is fast becoming a noxious weed, destroying the usefulness of whole fields, and requiring great labor for its eradication, from the fact that the plant must be uprooted, a very difficult task, as the root is often 3 or 4 feet in length, running straight down into the ground. It resembles a raw-hide whip, and is dark brown externally and whitish within. The plant has a whorl of radical leaves, from the center of which arise several stems curved like the forms of an umbrella (reversed), and covered with sharp spines that break off easily in the fingers. The flowers form long, terminal racemes, and are of a beautiful blue color marked with pink. The root, when properly burned, has been used as a fine-grade charcoal by artists. The plant is diuretic, besides possessing the pectoral properties of the above drug.

Anchusa officinalis, Linné; *Bugloss*, *Ox-tongue*.—This is a rough and hairy plant, bearing cymes of purple-blue flowers. Its root is white internally, and deep or blackish-brown externally, resembling in shape that of *alkanna*. The herb, as well as the root, has a mucilaginous taste, and both have emollient properties. A cold, or nearly cold, infusion provokes diuresis; a hot infusion provokes diaphoresis.

Pulmonaria officinalis, Linné; *Lungwort*.—This is a rough plant with a stem about 1 foot in height. Radical leaves ovate, cordate, scabrous; cauline ones ovate and sessile; flowers blue, in terminal clusters; calyx prismatic, 5-angled, 5-toothed, and as long as the tube of the corolla; corolla infundibuliform, with a cylindric tube, orifice hairy, in 5 lines alternating with the stamens; stigma emarginate; achenia roundish, obtuse, imperforate at base (W.). *Lungwort* is an herbaceous perennial, growing in Europe and this country, in northern latitudes. In Europe it is a rough-leaved plant, but in this country the whole plant is smooth. The leaves are much used in France in cough mixtures. (For uses, see next species).

Mertensia virginica, De Candolle, or *Virginian lungwort*, or *Cousip*, is frequently employed in the United States; it is the *Pulmonaria virginica* of Linneus, and the *Lithospermum pulchrum* of Lehman. It is a smooth, erect, and elegant plant, about 20 inches in height; radical leaves obtuse, obovate-elliptical, become from 5 to 6 inches long, and about two-thirds as wide, many-veined; cauline long-lanceolate, sessile. Flowers blue, in terminal clusters. Calyx 5-cleft, much shorter than the tube of the corolla, limb longer than the tube; corolla nearly an inch long, funnel-form, 4 times the length of the calyx, naked in the throat, and the much-spreading border slightly 5-lobed; stamens and style included; filaments slender. Disk bearing 2 glands as long as the ovaries. The stem and leaves are usually pellucid-punctate. This plant is found in alluvial banks, growing from western New York to Georgia and the western states, and flowering in May. Being a showy plant, it is frequently cultivated. The leaves of this plant are the parts used; they are without odor, and have a faint, astringent, somewhat viscid taste. Water extracts their properties (W.—G.). This and the preceding plant are demulcent

and mucilaginous, and may be used in decoction whenever this class of agents is indicated. They have been much used in *bleeding from the lungs, bronchial and catarrhal affections*, and others disorders of the respiratory organs.

Borago officinalis, Linné; *Borago*.—Levant. Naturalized in Europe and the United States. It has a fleshy white root; the plant is hispid, and the flowers blue or reddish, and borne in terminal racemes. The plant is often cultivated in gardens, and is occasionally used for salad. When fresh the plant is saline to the taste, and has an odor faintly recalling that of the common cucumber. The whole plant has been used in medicine. Braconnot and Lampadius found the plant to contain mucilage, resin, and a large amount of salts of potassium and calcium. Potassium nitrate has been found to the extent of 3 per cent. This plant is used to some extent in France, where it is employed in *fevers and pulmonary complaints* attended by excessive secretions. Owing to potassium nitrate, it is diuretic, and its mucilaginous properties render it demulcent and emollient. A fomentation of the flowers is used for *inflammatory swellings*, and for internal use an infusion of it is prepared (1 to 2 drachms to water 1 pint).

CYPRIPEDIUM (U. S. P.)—CYPRIPEDIUM.

"The rhizome and roots of *Cypripedium pubescens*, Swartz, and of *Cypripedium parviflorum*, Salisbury"—(U. S. P.).

Nat. Ord.—Orchideæ.

COMMON NAMES: *Ladies'-slipper*, *Yellow ladies'-slipper*, *American valerian*, *Umbel*, *Nerve-root*, *Yellow moccasin-flower*, *Noah's ark*.

ILLUSTRATION: Johnson's *Med. Bot. of N. A.*, Plate VIII (Cyp. pub.).

Botanical Source.—*Cypripedium pubescens* is an indigenous plant whose roots are perennial, fibrous, fleshy, undulated, or crooked, long, about a line in diameter, from which arise one or several round, leafy stems, growing from 12 to 18 inches high. The leaves are from 3 to 6 inches long, by 2 or 3 broad, sheathing, oblong-lanceolate, entire, veined, cauline, acuminate, pubescent, alternate, and generally the same number on each side. Its flowers are large, very showy, terminal, and solitary. Segments 4. Lobe of the style triangular-oblong, and obtuse; the sepals ovate, oblong, and acuminate; the petals long, linear, and contorted; the lip shorter than the other petals, compressed laterally, very convex, and gibbous above, pale-yellow, and from 1½ to 2 inches long (B.—R.—W.).

Cypripedium parviflorum has been considered a distinct species by some botanists, and as a mere variety by others. It differs from the above in having the lobe of the style acute, the leaves are broader, the flowers somewhat smaller, and the perianth more brownish-purple in color (W.).

History.—This plant is found in moist parts of the United States, in rich woods and meadows, flowering in May and June; its flowers are scentless. There are several varieties of it, all of which possess similar virtues, and the roots of which are undoubtedly collected, sold, and indiscriminately used with the official article (see *Related Species*).

The rhizomes and fibrous roots of these plants are the parts used in medicine. They should be gathered in autumn, cleansed from dirt, and carefully dried in the shade. They have a peculiar, slightly bitter, and rather nauseous taste, and a somewhat unpleasant odor. Alcohol, or boiling water, takes up their virtues, which, however, are impaired by boiling.

Description.—"Of horizontal growth, bent, 10 Cm. (4 inches), or less, long; from 3 to 5 Mm. (¼ to ½ inch) thick; on the upper side beset with numerous circular, cup-shaped scars; closely covered below with simple, wiry roots, varying from 10 to 15 Cm. (4 to 6 inches) in length; brittle, dark-brown, or orange-brown; fracture short, white; odor peculiar, heavy; taste sweetish, bitter, and somewhat pungent"—(U. S. P.).

Chemical Composition.—Mr. H. C. Blair (1866) found the root of *Cypripedium pubescens* to contain a volatile oil, a volatile acid, tannin, gallic acid, two resins, gum, glucose, starch, and ligneous matter; and salts of calcium, potassium, and magnesium. A more recent quantitative analysis by E. S. Beshore (*Amer. Jour. Pharm.*, 1887, p. 395) confirms these results, except that the tannic principle is distinct from both tannic and gallic acids. Alkaloids were not present, except a weak basic substance obtained in distilling the drug with milk of lime.

CYPRIPEDIN, an impure active principle, oleoresin-like, and incorrectly named cypripedin, has been procured from the root by a process similar to that named

for oleoresins of iris, xanthoxylum, etc. It may be given in doses of from 1 to even 3 grains, but is inferior to other preparations.

Action, Medical Uses, and Dosage.—Tonic, stimulant, diaphoretic, and antispasmodic. Its chief value is as a nerve stimulant in atonic cases, improving both the circulation and nutrition of the nerve centers (Scudder). It is a powerful agent. This root is valuable in all cases of *nervous excitability* or *irritability* unconnected with organic lesions, allaying the irritability, lessening the accompanying pain, producing a more calm and cheerful condition of the body and mind, and consequently favoring mental tranquillity, or sleep. Hence it has been of service in *hysteria*, *chorea*, *nervous headache*, *wakefulness* and *prostration*, *fevers*, *epilepsy*, from reflex irritation, and, indeed, in all cases of morbid irritation of the nervous system, from functional derangement or reflex irritation. It can be found very efficient in the *nervousness*, *hypochondria*, or *mental depression* accompanying certain forms of derangement of the digestive organs, which is more generally met with among females. Its action is greatly increased when combined with certain other agents, though this is not always necessary or advisable: combined with *Eupatorium aromatica* and *Scutellaria lateriflora*, it has proved beneficial in *neuralgia*, *delirium*, and *hypochondria*. A soothing syrup for *nervousness of children* is recommended by Prof. Scudder (*Spec. Med.*): R Specific cypridium, compound tincture lavender, aa fljii; specific lobelia, fl3j; simple syrup, fl3iii. Mix. The alcoholic extract is a good form of administration.

The following preparation has been used in *sick or nervous headache*, dependent on acid stomach: Take of *Nepeta cataria*, *Scutellaria lateriflora*, *Cypripedium pubescens* in powder, of each, $\frac{1}{2}$ ounce, pour on a pint of boiling water, and infuse for 15 or 20 minutes. Dose, 1 fluid ounce of the warm infusion after which, $\frac{1}{2}$ fluid ounce, every $\frac{1}{2}$ hour, for 3 or 4 hours, or until the headache ceases. Used thus, during 3 or 4 attacks of headache, it is asserted to have effectually effected permanent cures of this distressing complaint. An infusion is to be beneficial in the *pains of the joints* following *scarlet fever*. Although considered by many practitioners superior to valerian, yet it will be found inefficient in many instances where the European article will prove beneficial. Prof. MacDougal (*Amer. Jour. Pharm.*, 1896, p. 218), points out that the leaves and fruit of *Cypripedium spectabile* and *C. pubescens* exert a poisonous influence upon human skin, and that the source of this property resides in the glandular hairs which the plant is covered. Dose of alcoholic extract, from 10 to 20 grains; tincture, from 1 to 3 fluid drachms; infusion, from 1 to 4 fluid ounces; of the powder, 1 drachm in warm water, repeated as required; specific cypridium, 10 to 60 drops.

Specific Indications and Uses.—Insomnia, nervous irritability, neuralgia, and delirium, all from atony; menstrual irregularities, with despondency; tendency to dementia at climacteric; mental depression from sexual abuse.

Related Species.—The following species of *Cypripedium* possess properties analogous to those of the official drug:

Cypripedium spectabile, Willdenow; *Showy ladies'-slipper*.—Having crowded, ovate-lanceolate leaves, embracing each other; lobe of the style elliptic-cordate, obtuse; sepals broad, obtuse; lip longer than the petals, cleft before, white striped with purple, 2 inches long; petals broad; flowers very large, 2 or 3 on each plant, appearing in May and June; the whole plant pubescent (W.).

Cypripedium acaule, Aiton; *Low or Stemless ladies'-slipper*.—Having a bulbous root with numerous fleshy fibers; scape leafless, 1-flowered; leaves radical, in pairs, oblong, obtuse; lobe of the style round-rhomboid, acuminate, deflexed; lip longer than the lanceolate petals before, purple, or white, nearly 2 inches long, veiny; flowers solitary, terminal, with a lanceolate bract at the base, and appearing in May and June (W.—B.—R.).

Cypripedium candidum, Willdenow; *Small white, or White-flowered ladies'-slipper*.—Having a leafy stem, oblong-lanceolate leaves; lobe of the style lanceolate, somewhat obtuse; lip shorter than the lance-linear petals, white, about $\frac{1}{2}$ of an inch long; flowers terminal, solitary. The plant is slightly pubescent, seldom growing above a foot in height; the flowers appear in May and June (W.).

Cypripedium arietinum, Aiton, or *Ram's-head ladies'-slipper*.—Having a leafy stem; elliptic-ovate, striate-veined, sessile, amplexicaul leaves; lobe of the style orbicular, somewhat obtuse; lip as long as the petals, saccate, obconic before, red, and white-veined, hairy at the orifice, $\frac{1}{2}$ inch long; perianth greenish-brown. The flowers are mostly solitary with a leafy bract at the base, and appear in May and June (W.—B.—R.).

Cypripedium spectabile and *Cypripedium acaule* are said to possess more narcotic properties than the others, especially when inhabiting dark swamps.

DAMIANA.—DAMIANA.

The leaves and top of *Turnera aphrodisiaca*, Ward and Vasey (*Turnera diffusa*, Willdenow, var. *aphrodisiaca*, Urban).

Nat. Ord.—Turneraceæ.

COMMON NAME: *Damiana*.

Botanical Source, History, and Description.—This drug was introduced, in 1874, by Dr. F. O. St. Clair, and first appeared in the form of fluid extract, from the firm of Messrs. Helmick & Co., of Washington, D. C. Three distinct varieties or species of plants under the name of Damiana, are occasionally found upon the market, and are derived from as many different sources. In connection with the history of this drug, it may be stated that Mr. H. S. Wellcome read a paper upon the subject before the New York Alumni Association of the Philadelphia College of Pharmacy, October 15, 1875, at the same time exhibiting cuts of leaves, which were then upon the market, at that time, as "Damiana," reproduced by us (Fig. 92).

The true Damiana, the kind originally introduced by Dr. F. O. St. Clair, who obtained it from Mr. Eugene Gillespie, the United States Consul at Cape San Lucas, is derived from Mexico (see Fig. 93). It is evidently from a Mexican species of *Turnera*, proposed, by E. M. Holmes, to be a smooth-leaved variety of *T. microphylla*, De

Candolle. Prof. Lester F. Ward, on the examination of authentic specimens obtained by Dr. St. Clair, concluded that the drug is obtained from an undescribed species of *Turnera*, which Prof. Vasey and himself designated *Turnera aphrodisiaca*, and this name we shall accept for the Mexican damiana, until further light is thrown upon the subject. The result of Prof. Ward's examination can be found in the *Virginia Med. Monthly*, April, 1876. We extend our thanks to Dr. St. Clair for the aid given us in our endeavor to obtain the complete history of this drug, as well as for the specimens of original dami-

Turnera aphrodisiaca (true Damiana). Natural size.

ana so kindly furnished by himself. In this connection we can say that the leaves of Fig. 93, marked A A, are drawn from the original lot of damiana reported by Dr. St. Clair, in 1872.

The genus *Turnera* is a small family of chiefly tropical American plants allied to the Passifloræ. The flowers are small, yellow, and, in the species that produces damiana, subsessile near the end of the short branches. The calyx is tubular, hairy externally, colored like the petals, and 5-toothed at the apex. The petals are 5, yellow, and inserted on the tube of the calyx. The fruit, specimens of which are often found with damiana leaves, is dry, 1-celled, globular, and about the size of a large hemp seed (Fig. 93, B B). They are warty and rough externally, open by 3 valves, and contain from 3 to 6 kidney-shaped seeds (Fig. 93, C, magnified), attached to 3 parietal acetabula. Mexican damiana (*Turnera aphrodisiaca*), as found in market, consists of broken leaves mixed with fragments of the branches, and, sometimes, with seeds. The branches have a reddish-brown bark, and are covered, when young, with white, cottony hairs. The leaves (Fig. 93, natural size) are less than an inch long, obovate, wedge-shape, and taper at the base to a short, slender leaf-stalk; when young, they are covered with a slight pubescence, but become smooth

Mr. Wellcome's figures of Damiana (Chicago Pharmacist).

California Damiana (species of *Turnera*). $\frac{1}{2}$ natural size.

when old. They are distinctly pinnately veined, and the margin is toothed from 8 to 10 teeth.

A variety of damiana, closely resembling the preceding, is derived from California. It was ascertained by Mr. E. M. Holmes to be obtained from *Amicrophylla*, De Candolle, a small shrubby plant, native of lower California: northern Mexico. The leaves resemble the Mexican, but are broader, and covered with hairs on both sides (Fig. 92, A, preceding page).

A second kind of California damiana (also a species of *Turnera*) later made its appearance in the market. We are indebted to Mr. James G. Steele for the fact that this lot of damiana came from San Diego, California, and grew in the southern part of the state. The leaves have the shape of the Mexican damiana, but are larger, and very hairy, especially underneath (Fig. 94, $\frac{1}{2}$ natural size, preceding page).

The most common sophistication, however, once sold freely under the name of *Damiana*, is obtained from *Aplopappus discoideus*, De Candolle, a Composite

Fig. 95.

Aplopappus discoideus (spurious damiana). Natural size

of the section *Asteroides*. It is one of the few rayless species of *Aplopappus*, and is referred by some to the genus *Liatris*. It has no botanical relation to true damiana, and can only be considered a sophistication. The leaves (Fig. 95, A, natural size, and Wellcome's Fig. 92, preceding page) of this plant, as found on the market, are thick, firm, and so much broken up as the *Turnera*. The surface of the leaf is rough, resin-dotted, the mid-rib being prominent, but the veinlets are indistinct. The teeth are toward the apex of the leaf, and are rather remote and sharp. This can readily be distinguished from the true damiana by the presence of numerous flower-heads, which are common in all the specimens examined by us (Fig. 95, B). They are borne in axillary clusters of from 4 to 6 heads. The involucre is cup-shaped, and consists of numerous coriaceous imbricated scales, pubescent at the tips. The achenia (Fig. 95, B, magnified) are covered with a dense appressed pubescence, and bear a tawny, scabrous, spreading, unequal pappus.

The sensible properties of the leaves of all the varieties (or species) of *Turnera* found upon the market, under the name damiana, are similar. All have a fragrant odor, resembling lemon-balm, and a pleasant, slightly aromatic taste. The leaves impart their virtues readily to hot water, as well as to mixtures of water and alcohol. The spurious damiana, *Aplopappus discoideus* (Fig. 95), is entirely different. It resembles more nearly the *Grindelias*, both in odor and taste. It is very resinous, and imparts its characteristic properties most freely to strong alcohol. Water hardly affects it, and mixtures of water and alcohol imperfectly exhaust the resinous principles, and do not permanently retain in solution the portions as are extracted. This spurious damiana need never be unintentionally employed, as both the general appearance of the leaf, and the sensible characteristics, are entirely different from all the species of *Turnera*. It has been offered at half the price of true damiana.

Chemical Composition.—When distilled with water, the distillate from the leaves yields an essential oil. This oil is lighter than water, possesses the characteristic odor, and imparts to the plant its fragrance. Chlorophyll, hard soft resin, tannin, sugar, albuminoids, gum, and ash were found by Parsons in true damiana. Potassium chloride was found in spurious damiana by E. S. Wain in 1876. According to a more recent analysis of the leaves of damiana, by F. Pantzer (*Amer. Jour. Pharm.*, 1887, p. 69), alkaloids and glucosids were not obtainable. The yield of volatile oil obtained by distillation was 0.5 per cent.

Action, Medical Uses, and Dosage.—This drug has been almost eulogized for its positive aphrodisiac effects, acting energetically upon the genito-urinary organs of both sexes, removing *impotence* in the one, and *frigidity* in the other, whether due to abuses or age. Many physicians who have tried it, deny its possession of such virtues, but the friends of the drug attribute their failures to

use of the spurious articles. It will very likely be found to possess laxative, tonic, and diuretic properties only; and the aphrodisiac effects following its use, no more prove that these belong to it, than the same effects, that not unfrequently appear after the employment of many other agents, prove that such agents possess similar excitant virtues. Upon the system at large, it exerts a tonic influence, and is useful in some cases of *chronic cystic and renal catarrh*. It relieves *irritation of the urinary mucous membranes*, improves digestion, and overcomes *constipation* in some instances. In *respiratory disorders*, it may be employed to relieve *irritation and cough*, and, by its tonic properties, to check *hypersecretion* from the broncho-pulmonic membranes. The dose of the fluid extract is from $\frac{1}{2}$ fluid drachm to $\frac{1}{2}$ fluid ounce; specific damiana, 5 to 60 drops.

Specific Indications and Uses.—To relieve irritation of the genito-urinary mucous surfaces. (Sexual weakness and debility, with nervousness and depression [?]).

Other Aphrodisiacs.—*Hygrophila spinosa*. India. Seeds reputed diuretic and aphrodisiac. *Mura-Puama*.—A Brazilian wood containing an alkaloid, and reputed strongly aphrodisiac. Its botanical source is unknown (*Bull. of Pharm.*, 1892).

BURRA GOKEROO.—The carpels and whole plant of *Tribulus lanuginosus* are said to be aphrodisiac and diuretic. A fluid extract of the fruit, in doses of 20 to 60 drops, is recommended for *nocturnal pollutions*.

Sphæranthus indicus, *Mundi*, *Murmuria*, *Gorakhmundi*, *Kottakkarandai*.—India. Contains a rich, cherry-red, volatile oil (Dymock). It is reputed deobstruent, alterative, tonic, and aphrodisiac.

DECOCTA.—DECOCTIONS.

The solution procured from the various parts of plants, by boiling them in water, is called a decoction. Decoctions are generally prepared from those articles which do not readily yield their active constituents to water, at a temperature below 100° C. (212° F.), yet it must be remembered, that as most plants contain starch, gum, and other inert matters, which are readily soluble in boiling water, these will generally be found associated with the remedial principles in a decoction. Medicines containing volatile principles, or substances liable to be changed into insoluble and inert matters at a boiling heat, should never be subjected to decoction. When, however, decoction is determined upon, the drugs should be sliced, bruised, or powdered, according to their character, and placed in an earthenware, glass, or iron vessel of suitable size, the latter being lined internally with enamel. In most instances, tin vessels may be employed, but copper, brass, iron, or zinc vessels, on account of their liability to oxidation, or incompatibility with such principles as tannic acid, are apt to prove injurious, and should not, therefore, be used. The water employed should be pure and clear, and the boiling should not be continued for too long a period. The vessel should be kept covered. The decoction should be strained before it cools.

In decoctions where several drugs are employed, each should be placed in the boiling water at periods adapted to the time required to obtain its soluble constituents. Some plants require to be boiled for some minutes, while others yield all their virtues if added toward the termination of the process. Volatile agents should be added after the decoction, which should be kept closely covered until cold, has been removed from the fire.

Decoctions are now seldom ordered from the pharmacist, but are made a matter of domestic management; hence, with but few exceptions, a list of decoctions is omitted herein, an explanation of the general rules relating to them being deemed sufficient. Physicians usually prepare decoctions by allowing 1 ounce of the drug to 1 pint of water, the dose depending on the activity of the agent, or the physiological effect required.

Decoctions are liable to speedy change or decomposition; consequently they should be made in small quantities. Decoctions have been largely superseded by the more stable and elegant pharmaceutical preparations of the present. Owing to the fact, however, that many are occasionally employed, we give formulæ for those most important. The *U. S. P.* gives the following general method for the preparation of decoctions:

"An ordinary decoction, the strength of which is not directed by the physician nor specified by the Pharmacopœia, shall be prepared by the following formula: Take of the substance, coarsely comminuted, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M]. Put the substance into a suitable vessel provided with a cover, pour upon it one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M] of cold water, cover it well and boil for 15 minutes. Then let it cool to about 40°C. (104° F.), express, strain the expressed liquid, and pass enough cold water through the strainer to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M]. CAUTION.—The strength of decoctions of energetic or powerful substances should be specially prescribed by the physician"—(*U. S. P.*).

The Pharmacopœia, of 1880, directed decoctions of 10 per cent drug strength. Those of the present *U. S. P.* have a strength of 5 per cent, and only two are recognized.

Decoctions Formerly Official.—The following decoctions were official in the *U. S. P.* of 1870: DECOCTUM CHINAPHILÆ, *Decoction of Pipsissewa*; DECOCTUM CINCHONÆ FLAVÆ, *Decoction of Yellow Cinchona*; DECOCTUM CINCHONÆ RUBRÆ, *Decoction of Red Cinchona*; DECOCTUM CORNUS FLORIDÆ, *Decoction of Dogwood*; DECOCTUM DULCAMARÆ, *Decoction of Bittersweet*; DECOCTUM HEMATOXYLI, *Decoction of Logwood*; DECOCTUM HORDEI, *Decoction of Barley*; DECOCTUM QUERCUS ALBÆ, *Decoction of White Oak Bark*; DECOCTUM SENEGÆ, *Decoction of Senega*; DECOCTUM UVÆ URSI, *Decoction of Uva Ursi*.

All were prepared (excepting decoction of barley) by boiling for 15 minutes a troy ounce of the drug in a pint of water, straining and finally bringing the finished product to 1 pint by adding to it a sufficient quantity of water.

DECOCTUM ALOES COMPOSITUM (N. F.)—COMPOUND DECOCTION OF ALOES.

Preparation.—*Formulary number, 29:* "Extract of aloes (*U. S. P.*), ten grammes (10 Gm.) [154 grs.]; myrrh, seven and one-half grammes (7.5 Gm.) [115 grs.]; saffron, seven and one-half grammes (7.5 Gm.) [115 grs.]; potassium carbonate, five grammes (5 Gm.) [77 grs.]; extract of glycyrrhiza, in powder, thirty-five grammes (35 Gm.) [1 oz. av., 102 grs.]; compound tincture of cardamom (*U. S. P.*), two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄3, 218 M]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M]. Reduce the myrrh and extract of aloes to a coarse powder, mix this with the potassium carbonate and extract of liquorice in a suitable covered vessel, and pour on six hundred cubic centimeters (600 Cc.) [20 fl̄3, 138 M] of water; boil for 5 minutes and add the saffron. When cool, add the compound tincture of cardamom, and allow the mixture to macerate for 2 hours; then filter through flannel and add enough water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M]. This preparation should be freshly made when wanted for use"—(*Nat. Form.*).

This decoction contains the same ingredients, and varies but little in proportions from that official in the *British Pharmacopœia*.

Action, Medical Uses, and Dosage.—Compound decoction of aloes is employed like compound tincture of aloes and myrrh, though the decoction is less stimulating. A gentle cathartic and emmenagogue for atonic states, as *constipation* and *amenorrhœa*. Dose, $\frac{1}{2}$ to 2 fluid ounces.

DECOCTUM CETRARIE (U. S. P.)—DECOCTION OF CETRARIA.

SYNONYM: *Decoction of Ireland moss.*

Preparation.—"Cetraria, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M]. Cover the cetraria in a suitable vessel, with four hundred cubic centimeters (400 Cc.) [13 fl̄3, 252 M] of cold water, express after half an hour, and throw the liquid away. Then boil the cetraria with one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M] of water for half an hour, strain, and add enough

cold water, through the strainer, to make the product, when cold, measure one thousand cubic centimeters (1000 Cc.) [33 fl $\bar{3}$, 391 M.]—(*U. S. P.*).

The object of macerating the moss in cold water is to remove a part of the bitter principle, a process objected to by many, who consider it no better than the ordinary demulcents, if it be deprived of this peculiar bitter. The *British Pharmacopæia* directs decoction of Iceland moss to be boiled 10 minutes.

Action, Medical Uses, and Dosage.—(See *Cetraria*). The dose is from 2 to 4 fluid ounces from 3 to 5 times a day.

DECOCTUM GRANATI RADICIS.—DECOCTION OF POMEGRANATE ROOT.

SYNONYM: *Decoctum corticis radicis granati.*

Preparation.—Boil 2 ounces (av.) of sliced pomegranate-root bark in 2 pints (Imp.) of distilled water, until reduced to 1 pint (Imp.). Strain, and if necessary, by pouring sufficient distilled water on the contents of the strainer, bring the finished decoction to measure 1 pint (Imp.). This accords with the *British Pharmacopæia*.

Action, Medical Uses, and Dosage.—Used internally to expel tapeworms (see *Granatum*). Also as a wash for mucous, serous, and sanguineous fluxes, and for relaxed membranes and discharging ulcers.

The following has been a standard with Eclectic physicians for many years: "Put 4 pints of water and 8 ounces of selected bark, into a kettle and boil well; then strain through muslin; press well. Add the contents of the strainer again to the same amount of water (4 pints), boil and strain as before. Mix the two liquids, and evaporate to the measure of 1 pint. Allow the decoction to cool before administering.

Directions for Use.—"The patient should fast 1 day, and on retiring should take 2 compound cathartic pills to loosen the bowels. Next morning on arising, take a good dose of Rochelle salts, and as soon as there is a profuse stool, take 2 or 3 ounces of decoction of pomegranate. If it be retained on the stomach, the worm will probably pass with the next stool. If the decoction is vomited, as is probable give another dose, after waiting a couple of hours for the stomach to rest."

DECOCTUM HÆMATOXYLI.—DECOCTION OF LOGWOOD.

Preparation.—Take 1 ounce (av.) of logwood (in chips), 55 grains of coarsely-powdered cinnamon bark, and 1 pint (Imp.) of distilled water. Boil the logwood in a closed vessel for 10 minutes, adding the cinnamon toward the end of the boiling period. Strain, and, by pouring sufficient distilled water upon the contents of the strainer, bring the decoction to measure 1 pint (Imp.).

The *British Pharmacopæia* directs the foregoing method which is improved by continuing the boiling longer in order to better exhaust the chips. A former *U. S. P.* process directed 1 ounce of logwood in 2 pints of water, to be reduced by boiling to 1 pint.

Action, Medical Uses, and Dosage.—(See *Hæmatoxylon*.) A mild astringent. Dose, from 1 to 2 fluid drachms (children), to 2 fluid ounces (adults)

DECOCTUM HORDEI.—DECOCTION OF BARLEY.

SYNONYM: *Barley water.*

Preparation.—Wash 2 ounces (av.) of pearl barley in cold water and throw away the washings. Then boil the barley in a closed vessel for 20 minutes, in 1½ pints (Imp.) of distilled water, and strain. This accords with the *British Pharmacopæia*. Boiling the barley for 1 or 2 minutes will remove mustiness or other unpleasant extraneous matter, if present, better than washing in cold water.

Action, Medical Uses, and Dosage.—An admirable unirritating, nutritious, and readily digestible drink for fevers or irritable states of the gastro-intestinal and

urino-genital tracts. May be sweetened or acidulated when not contraindicated.
Dose, 1 to 4 or more fluid ounces.

DECOCTUM PAPAVERIS.—DECOCTION OF POPPIES.

Preparation.—Boil, in a closed vessel, for 10 minutes, 2 ounces (av.) of bruised poppy capsules in $1\frac{1}{2}$ pints (Imp.) of distilled water. Strain, and pouring sufficient distilled water on the contents of the strainer, bring the measure of the decoction to 1 pint (Imp.). This is official in the *Br. Pharm.* The residue should not be rejected, as they add to the emolliency of the preparation.

Action and Medical Uses.—This is a feebly anodyne, emollient, and mucilaginous preparation, used locally as a fomentation to *inflammatory parts*.

DECOCTUM SARSÆ.—DECOCTION OF SARSAPARILLA.

SYNONYM: *Decoctum sarsaparillæ.*

Preparation.—Digest for 1 hour $2\frac{1}{2}$ ounces (av.) of transversely cut *Jac. sarsaparilla* in $1\frac{1}{2}$ pints (Imp.) of distilled water. Then, in a closed vessel, for 10 minutes. Cool, strain, and by the addition of distilled water, if necessary, bring the finished product to the measure of 1 pint (Imp.). This accords with the *British Pharmacopœia*.

Action, Medical Uses, and Dosage.—Many prefer to use the bruised root to avoid boiling, for the longer the preparation is boiled the weaker it becomes. Infusion is preferable to the decoction. Digestion of the root at a temperature about 80° C. (176° F.) is probably the best method. This decoction is but little employed. Its uses are those of sarsaparilla. Dose, 2 to 4 fluid ounces 4 times a day.

DECOCTUM SARSAPARILLÆ COMPOSITUM (U. S. P.).—COMPOUND DECOCTION OF SARSAPARILLA

Preparation.—“Sarsaparilla, cut and bruised, one hundred grammes (Gm.) [3 ozs. av., 231 grs.]; sassafras, in No. 20 powder, twenty grammes (20 Gm.) [309 grs.]; guaiacum wood, rasped, twenty grammes (20 Gm.) [309 grs.]; ginger rhiza, bruised, twenty grammes (20 Gm.) [309 grs.]; mezereum, cut and bruised, ten grammes (10 Gm.) [154 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 Ml.]. Boil the sarsaparilla and guaiacum wood for half an hour in a suitable vessel with one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 Ml.] of water. Then add the sassafras, glycyrrhiza, and mezereum, cover the vessel well, and macerate for 2 hours. Finally strain and add enough cold water, through the strainer, to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 Ml.]”—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This decoction may be given in *scrofulous* and *syphilitic* conditions as an alterative and mild diaphoretic. It is likewise employed in certain *cutaneous*, *rheumatic*, and other affections dependent on *dyscrasia*. Mezereum and sarsaparilla are its chief active agents. It is patterned after the *Decoctum lusitanicum*, or *Lisbon diet drink*. Somewhat similar preparations are employed in Germany under the names *Decoctum Zittmanni fortius* and *Decoctum Zittmanni mitius*, or *Zittmann's stronger and milder decoctions*, which contain, however, cinnabar and calomel. The compound decoction of sarsaparilla may be given in doses of 3 to 6 fluid ounces, 3 times a day.

DECOCTUM SCOPARII.—DECOCTION OF BROOM.

Preparation.—The *British Pharmacopœia* directs the preparation of decoction of broom essentially as follows: Boil in a covered vessel 1 ounce (av.) of broom tops in a pint (Imp.) of distilled water for 10 minutes. Strain and pour

the residue in the strainer sufficient distilled water to produce a pint (Imp.) of the finished product.

Action, Medical Uses, and Dosage.—This is actively diuretic, and is useful in *dropsical disorders*. Care must be taken in its administration, as it may provoke renal and cystic irritation. The dose is about 2 fluid ounces, given so that from $\frac{1}{2}$ to 1 pint is taken in 24 hours.

Related Preparation.—DECOCTUM SCOPARII COMPOSITUM. *Compound decoction of broom.* Take of broom-tops, juniper berries, and dandelion root, of each, $\frac{1}{4}$ troy ounce; water, Ojss. Boil down to 1 pint. Dose, from 1 to 2 fluid ounces.

DECOCTUM TARAXACI.—DECOCTION OF DANDELION.

Preparation.—Slice and bruise 1 ounce (av.) of dried dandelion root, and boil it in 1 pint (Imp.) of distilled water for 10 minutes; strain, and pour upon the residue in the strainer enough distilled water to make the finished product measure 1 pint (Imp.). This is in accordance with the *British Pharmacopœia*. A little orange peel added at the end of the boiling period, is said to increase its usefulness. It does not keep well and must be freshly prepared.

Action, Medical Uses, and Dosage.—(See *Taraxacum*.) This may be employed as a vehicle for the simple bitters. The dose is about 2 fluid ounces before meals.

DECOCTUM ULMI.—DECOCTION OF ELM-BARK.

Preparation.—Take $2\frac{1}{2}$ ounces (av.) of small pieces of elm-bark and boil in 1 pint of distilled water, for 10 minutes, in a suitable covered vessel; strain, and pour upon the residue in the strainer sufficient distilled water to make the finished decoction measure 1 pint. This is in accordance with the *British Pharmacopœia*, of 1867.

Action, Medical Uses, and Dosage.—A mucilaginous, astringent, and bitter decoction. (For uses see *Ulmus*). Dose, from 2 to 4 fluid ounces. Mucilage of slippery elm is preferable.

DIERVILLA.—BUSH HONEYSUCKLE.

The root, leaves, and twigs of *Diervilla trifida*, Mœnch (*Diervilla canadensis*, Mühlenberg).

Nat. Ord.—Caprifoliaceæ.

COMMON NAMES: *Bush honeysuckle, Gravelweed.*

Botanical Source.—This plant is a low shrub, with a branching, pithy stem, about 2 or 3 feet high. The leaves are from 2 to 4 inches long by 1 to $1\frac{1}{2}$ broad, ovate, acuminate, finely serrate, opposite, deciduous, and borne on short petioles. The peduncles are axillary and terminal, dichotomous, and from 1 to 3-flowered. The flowers are greenish-yellow. Calyx tube oblong, limb 5-cleft, with 2 bracts; corolla twice as long as the calyx, greenish-yellow, 5-cleft, funnel-shaped; border 5-cleft, spreading. Stamens 5, which, with the style, are much exserted; stigma capitate. Capsule oblong, attenuate above, 2-celled, and naked, with many seeds (W.).

History.—This is a woody shrub, growing in the United States from Canada to Carolina, in hedges and thickets, and by the sides of fences and rocks, flowering in June. The leaves, twigs, and roots are the parts used, and they yield their properties to alcohol, and boiling water in infusion.

Action, Medical Uses, and Dosage.—Diuretic, astringent, and alterative. A cold infusion of the bruised leaves and twigs, used freely, has been very beneficial in *inflammation of the bladder*, with gravelly deposit in the urine, in *nephritic* and *calculous affections*, and in *gonorrhœa*. The root, in decoction or syrup, has been lauded for the cure of *syphilis*. Externally applied in *erysipelas*, or *erysipelatous inflammations*, and over the *inflamed surface* occasioned by the rhus, ivy, or poison vine, it soon relieves the itching, burning, inflammation, and swelling.

DIGITALIS (U. S. P.)—DIGITALIS.

"The leaves of *Digitalis purpurea*, Linné, collected from plants of the second year's growth"—(U. S. P.). (*Digitalis tomentosa*, Link et Hoffmann).

Nat. Ord.—Scrophularineæ.

COMMON NAMES: *Foxglove*, *Purple foxglove*.

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 195; Woodville, *Med.* Plate 24.

Botanical Source.—Foxglove is a handsome biennial plant, with a white root of numerous long and slender fibers. The stem is straight, wand-like,

Digitalis purpurea.

mostly simple, roundish, with several slight angles, downy, 3 or 4 feet high. The leaves are alternate, ovate, or elliptic, crenate, downy, rugged, and veiny, of a dull-green, tapering at base into winged footstalks, the radical ones being largest. The flowers are numerous, large, pendulous, scentless, purplish-rose, elegantly marked with eye-like spots, and hairy within, and borne in terminal, 1-sided, erect, simple racemes. The corolla is monopetalous, campanulate, ventricose, contracted at the base into an oblique limb; upper lip emarginate, lower trifid, with the middle lobe the largest. The calyx is composed of 5 acute sepals, persistent, and much shorter than the corolla; the uppermost are the narrowest. The stamens are didynamous, and inserted into the middle of the corolla; anthers large, acute, naked; style simple; stigma bilamellate. The capsule is ovate, sharp-pointed, with a septum, dehiscent; seeds many, small, grayish-brown, pitted, and oblong.

History.—Foxglove is indigenous to the larger portions of Europe, and has been introduced into the United States, where it flowers in June and July. It grows in thickets, along wood borders, and on the commons, preferring a sand-soil, not too

often found where limestone abounds. Though also a mountain plant in warmer portions of Europe, it is not found in the Swiss Alps and Jura Mountains (*Pharmacographia*). It has been naturalized in the Isle Chiloe of South America (Cunningham). The official part is the leaves, though the seeds will also be found efficient. The leaves should be collected from the second year's growth while the plant is in bloom—Duncan says "before the inflorescence"—select only those which are fully developed, and separating from them the inert petioles and mid-veins; they should then be dried by exposure to a current of dry air, being placed in a drying stove, or by being inclosed in a hot air press. Much care is necessary in preserving them for medicinal purposes. When well prepared the powder has a fine green color, and retains the intense bitterness of the leaves. The leaves, when dried or in powder, should be placed in opaque, glass-closed vessels, to protect them from the deleterious influence of dampness and light; and the drug should be renewed annually, as it loses its virtues by age. The seeds, though but little used, retain their properties much better than the leaves. Fresh foxglove leaves have a slight virose odor, which, by desiccation becomes feebly narcotic, with an acrid, bitter, disagreeable taste and a dark-green color. Their properties are yielded to alcohol, ether, water, or diluted acids.

Description.—The U. S. P. describes digitalis leaves as follows: "From 10 to 15 Cm. (4 to 12 inches) long; ovate or ovate-oblong; narrowed into a petiole; crenate, dull green, densely and finely pubescent; wrinkled above; paler and reticulate beneath; midrib near the base broad; odor slight, somewhat tea-like; taste bitter and nauseous. An infusion prepared with 1 part of digitalis and 10 parts of boiling water, and allowed to cool, has a peculiar odor, turns blue litmus paper red, and upon the addition of a few drops of ferric chloride T.S., acquires a darker color; a brown precipitate appearing after a few hours. The infusion, diluted with 3 parts of water, becomes turbid on the addition of a few drops of tannic acid T.S."—(U. S. P.).

Chemical Composition.—*Digitalis purpurea* was first investigated chemically by Destouches, in 1809, although the plant has been known in botanical literature through the writings of Leonhard Fuchs since 1542. Dulong d'Assa

(1827) appears to have been the first to recognize the bitter substance, digitalin, "as an individual body, capable of forming an insoluble compound with infusion of galls (*Archiv. der Pharm.*, 1870, p. 28). This reaction was employed by later observers in the making of digitalin, *e. g.*, by Homolle and Quevenne. In 1844, the Société de Pharmacie of Paris awarded a prize to these chemists for having succeeded in isolating the active principle of digitalis; yet their digitalin, though crystalline and no doubt purer than similar preparations of their predecessors, was by no means a uniform substance. Neither were the preparations obtained by later chemists, *e. g.*, Walz (1846-58), and Kosman (1861 and later), individual substances. Nativelle (1867-74) prepared *digituline cristallisée*, which at last was believed to be pure. Meanwhile a commercial distinction had been established between German digitalin (originating from Walz's preparation), an amorphous powder easily soluble in water and alcohol, less soluble in chloroform, and very little soluble in ether; and French crystalline digitalin (that of Homolle and Quevenne, and Nativelle), easily soluble in chloroform and alcohol, but hardly soluble in water and ether. In this connection it may be stated that the *French Codex* gives detailed directions for the preparation of both *digitaline amorphe* and *digitaline cristallisée*, the yield of the latter being 1 gram from each kilogram of leaves. To Schmiedeberg (1874) we are indebted for a critical study of the more important digitalines of commerce. He arrived at the conclusion that these preparations were composed mainly of the following principles: *Digitonin*, *digitoxin*, *digitalin*, and *digitalein*. The first is an inactive glucosid, while the three others have the property of acting upon the heart, *digitoxin* possessing this power in a most pronounced degree. The more recent researches of Kiliani have materially extended our knowledge of the chemical nature of these substances.

Digitonin.—This medicinally inert substance was obtained amorphous by Schmiedeberg. Kiliani found that it will easily crystallize from 85 per cent alcohol, and that by means of this solvent it may be abstracted from water-soluble commercial digitalin. When crystallized, digitonin is less soluble in water than when amorphous; its solution foams when shaken. It is little soluble in alcohol, insoluble in ether, chloroform, and benzin, and forms an insoluble tannate. Warmed with diluted hydrochloric acid, it splits into *digitogenin* (observed by Schmiedeberg), galactose, and dextrose (Kiliani, *Ber. d. d. Chem. Ges.*, 1890).

Digitoxin.—This forms the main constituent of Nativelle's digitalin. It is insoluble in water, although the presence of other digitalis glucosids or extractive matters may render it more soluble. It dissolves freely in alcohol and chloroform, slightly in ether, but is insoluble in petroleum ether (Keller, 1897). It yields a precipitate with tannic acid, but not with basic acetate of lead. Schmiedeberg could not establish the presence of sugar as a constituent of digitoxin, although he obtained *toxiresin* by the action of acids. Recently Kiliani succeeded in resolving digitoxin ($C_{41}H_{66}O_{16}$), into *digitoxigenin* and a substance, *digitoxose* ($C_6H_{12}O_6$), resembling sugar (*Archiv. der Pharm.*, 1896, p. 481).

Digitalein.—The existence of this substance as an individual body is questioned by such authorities as Kiliani and C. C. Keller (*Ber. d. d. Pharm. Ges.*, 1897, p. 125), who pronounce it to be most likely a mixture of digitonin with traces of digitoxin and digitalin.

Digitalin.—Schmiedeberg proved this to be a glucosid, but, excepting a resinous substance which he called *digitaliresin*, was unable to obtain a well defined product of hydrolysis. Homolle and Quevenne's digitalin he pronounced to be composed mainly of digitalin and digitaliresin. He also found that digitalin acts on the heart, but in a much milder form than *digitoxin*. It is soluble in water.

Kiliani, considering digitalin a useful therapeutic agent, made it a commercial product under the name *digitalinum verum*, believing it to be a uniform substance, notwithstanding its refusal to crystallize. He finally succeeded in resolving it into *digitaligenin*, a well-defined crystalline body, dextrose, and *digitalose* (*Archiv. der Pharm.*, 1892, p. 250; also see *Pharm. Jour. Trans.*, 1895, p. 29, for details of preparation of *digitalinum verum*). As regards the therapeutic use of *digitalin*, there has been a tendency in late years to give preference to *digitoxin* and the preparations containing it, although it was formerly discarded on account of its insolubility in water, as well as the violent action it exerts when in solution. (See *Amer. Jour. Pharm.*, 1897, p. 450, for Keller's process of preparation). Keller's

test for digitoxin is as follows: Dissolve digitoxin in glacial acetic acid containing ferric chloride; float this solution upon strong sulphuric acid. At the line of contact a dark zone appears, and after a few minutes the acetic acid liquor becomes dark blue. This reaction takes place with $\frac{1}{10}$ of a milligramme of digitoxin in 1 Cc. of acetic acid. As to the occurrence of the digitalis glucosids in leaves and seeds, Keller holds (1897) that digitoxin, digitonin, and digitalin in different proportions may be obtained from both sources. The amount of digitoxin in the leaves was observed by him to vary from 0.26 to 0.62 per cent. Kiliani, on the other hand, remarks (*Pharm. Jour. Trans.*, 1895, p. 120, and 1896, p. 289), that digitalis seeds contained digitonin and digitogenin, and are besides the (more remote) source of his digitalinum verum, which does not occur in the leaves. The latter contain principally digitoxin, which is not to be found in the seeds. The relation of Arnaud's *digitaline cristallise* (see *Jour. Pharm. Chim.*, 1889, pp. 454 and 514) to the aforementioned principles remains yet to be established.

Other Constituents of Digitalis.—Morin (1845) isolated an acid substance which he called *digitalic acid*, which Flückiger believed to have been malic acid merely; and volatile *antirrhinic acid* which resembles valerianic acid. *Digitalosmin* was an odoriferous substance having a nauseous taste, obtained by Walz in 1852. The sugar *inosit*, was discovered in the leaves by Marmé, in 1864. The ash in the leaves was found by Flückiger to be 10.56 per cent. Infusions of digitalis sometimes gelatinize, owing to the precipitation of modified pectin matter, the result of the influence of micro-organisms. This change is facilitated (Dr. Forcke, *Amer. Jour. Pharm.*, 1890), by the employment of the petioles in making the infusion, as they are richer in pectin matter than the leaf itself. The U. S. P., and other pharmacopœias as well, direct that leaves of the second year's growth be employed, as the infusion from leaves collected in the first year are believed to be prone to gelatinize.

Action and Toxicology.—In single large doses, digitalis is an irritant-narcotic poison, producing gastro-intestinal irritation, nausea, vomiting, and very abundant alvine evacuations. Its action is afterward spent upon the nervous system, causing vertigo, dimness of sight, delirium, convulsions, or a general debility, and finally death (E. & V.). A slow, feeble, irregular pulse and suppression of urine are generally present. When given in medicinal doses, too long continued, or in quantities to exert an immediate action on the system, it causes an increased discharge of urine, reduces the pulse from 70 beats in a minute to 30, with languor, nausea, occasionally anxiety and salivation, a sense of weight, or constriction, obtuse pain in the head, giddiness, disordered vision, mental disturbance, and rarely spectral illusions; not unfrequently a huskiness of the voice is present, the result of irritation of the fauces, trachea, etc. The nausea produced by digitalis, and more quickly by digitalin and digitoxin, is preceded by malaise, faintness, and depression, and is exceedingly distressing. Vomiting temporarily relieves it, the vomited material being first dark-green, afterward yellow. Prostration becomes so great that the individual can not stand without help, and an intense disgust for food is experienced. Familiar objects are unrecognizable—a disturbed vision with yellowness or blueness supervening. Persons are recognized only by their voices. These effects, if not fatal, may last several days, the sleep being disturbed by nightmare and general unrest. Finally sound sleep and a voracious appetite quickly restore the individual to normal health. If the use of the remedy be persisted in, these effects will continue to increase until the poisonous symptoms, first referred to, become developed. Dr. Fuller states that digitalis stimulates the muscular fibers of the heart, and augments the contractility of the capillaries; when it kills it does so not by producing paralysis of the heart, but by giving rise to tonic contraction and spasm of that organ.

Primarily, digitalis acts upon the heart as a stimulant, increasing the tension and pulse rate; larger doses, acting as a sedative, reduce the pulse, but the tension remains unaffected. The diastole is prolonged while the systole is increased in vigor. A lethal dose produces a tetanic contraction of the heart muscle, particularly of the left ventricle, the heart being arrested in systole. The effect of the stronger systole and the prolonged diastole is a reduction of the number of pulsations. Not only does a contraction of the heart muscle take place, but a marked contraction of the arterioles also results, so that the blood current

is reduced in size and the amount of blood sent through the arteries to the different parts of the system is decreased. A rise of blood pressure then ensues from the resistance of the narrowed arterial calibre and increased systolic action. From the fact that, after the administration of full medicinal doses, a change of posture, as from the recumbent to upright position, occasions a greatly increased number of pulsations and a marked diminution of cardiac force, it has been assumed that no real power is imparted to the heart by digitalis. This has been explained by others as an occurrence only met with when the tonic action is about to verge into that of exhaustion from overstimulation. Lethal doses cause the tetanic contraction above mentioned, obstructing the passage of blood through the organ and death takes place from spasm, resulting in syncope. In woman, digitalis, like ergot, causes contraction of the uterine fibers of an enlarged or gravid uterus, thereby arresting hemorrhage; in man it primarily lessens the supply of blood to the erectile tissues of the penis, preventing or enfeebling erections and consequently diminishing the venereal desires.

Many affirm that digitalis has no direct diuretic power. In health it is known to generally lessen the secretion of both the solid and fluid constituents of the urine. Some contend that it slightly increases the flow of urine. It is more than probable that, when diuresis is the result of its administration, it is in those cases in which a diminished secretion of urine is due to debility or some other form of cardiac embarrassment. Others, however, maintain different views, and Brunton asserts that diuresis produced by it in dropsy is due to a special action of the drug upon the Malpighian bodies, and not to augmented blood pressure alone.

Poisoning by digitalis may be produced by $\frac{1}{4}$ grain of digitalin (equal to 8 grains of good powdered digitalis leaves), and Taylor (*Med. Juris.*, p. 229) states that doses of from $\frac{1}{4}$ to $\frac{1}{2}$ grain would probably produce death. Cold, belladonna, ergot, etc., increase the activity of digitalis, while aconite opposes its action. According to Bartholow, the most complete antagonist to digitalis, physiologically speaking, is saponin. Strychnine is also a physiological antagonist.

The poisonous effects of digitalis are best counteracted by first evacuating the stomach by the free use of warm liquids and mechanical emetics, if any of it is supposed to remain in the stomach, and then administering brandy, wine, opium, black coffee, ammonia, ammonium carbonate, or other stimulants, with sinapisms to the wrists and ankles. Both external and internal heat should be used. A solution of tannic acid might be of service, by forming an insoluble tannate of digitalin. Preparations containing tannin, such as tea, etc., may be given. Iron sulphate and chloride are recommended by some as chemical antagonists. Digitalin produces similar effects on the system with digitalis, but its internal administration is hazardous, and demands much care and prudence. After death from digitalis the gastric membranes were found partially inflamed and the meninges of the brain much injected (Taylor).

Action, Medical Uses, and Dosage.—In medicinal doses, foxglove is sedative and secondarily diuretic. It has been employed with asserted advantage in febrile diseases, acute inflammations, insanity, neuralgia attended with irritative fever, asthma, hemoptysis, whooping-cough, palpitation of the heart, epilepsy, and as a diuretic in dropsy, connected with diseased heart or kidneys. As a sedative in fevers and inflammations, its use is not to be commended, in view of the fact that it tends to produce unpleasant gastric disturbances and other disquieting symptoms. It has been claimed that it is of great service in scarlatina, both for the purpose of producing sedation and keeping the kidneys active, thus tending to avert post-scarlatinal dropsy and uræmia. That it will do this without some heart debility being present also, is by no means well established, while, on the contrary, its unpleasant, nausea-provoking properties make it an undesirable remedy. The same is true of it in typhoid and other febrile disorders. It should always be used with care, on account of its cumulative effect, which may otherwise occasion an unexpected fatality. Such cumulative action is not, however, likely to occur unless the dose be too large and too frequently repeated, thus overlapping the successive doses when, like any other remedy so administered, its effects will become cumulative. The old view of cumulative effects from small doses suddenly developing toxic symptoms, is not now held by many, yet it is proper to be cautious and to

keep within the bounds of safety. When its constitutional effects become too great, the exhibition of the remedy should be omitted from time to time, in order to guard against the results of this alarming accumulation. When its sedative effect is too great, it is best counteracted by the use of wine and opium compound.

Like ergot, by its contractile power over the capillaries, digitalis is a remedy for *asthenic hemorrhage*, *metrorrhagia*, *menorrhagia*, *purpura hemorrhagica*, *gout*, and *hemoptysis*, though it is of less value in the last-named disorder than in that of uterine origin. However, as a remedy for hemorrhage it will not take as important a place when other drugs are so preëminently superior for this purpose. Digitalis has not found favor with the majority of practitioners of our time in *pulmonic* and *bronchial inflammations* (except *pulmonary congestion*), as it has not some of the members of the Allopathic persuasion. No materia medica is so inefficient in broncho-pulmonary remedies as the Eclectic, and, as digitalis is so uncertain in its effects in these disorders, and so liable to occasion intestinal disturbances, it is not likely to become at all important with us in this branch of therapy. In *nervous disorders* it has a limited usefulness. In *chronic mania*, *maniacal delirium*, and in *delirium tremens* it has been administered with some success, but as the indications for its selection, given by different observers, are diametrically opposed, it is difficult to make a selection of the proper case. It is probable, however, that it is of some value in *congestive hemicrania*, *Exophthalmic goitre*, in the anemic young, and associated with cardiac weakness and dilated vessels, is often benefited by digitalis combined with restoratives.

It is in *heart troubles of an asthenic character*, however, that digitalis shows its power as a true remedy. As a general statement it may be said that it is indicated by a weak, rapid, and irregular heart and low arterial tension—a condition of asthenia; and it is contraindicated by a strong, vigorous heart action and high arterial tension—a sthenic state. As Prof. Locke very properly states, "Digitalis is the true opium for the heart."

Digitalis primarily excites the vaso-motor nerves only, those which are distributed to the ventricular portion of the heart, contracting the blood vessels and the muscle; temporarily quickens the heart's action, and secondarily, through paralysis of those nerves, dilatation of the blood vessels ensues with consequent relaxation of the muscular tissues. Hence in *cardiac hypertrophy*, when simply compensatory, it should not be given at all; in *cardiac dilatation* it should be given in order to produce its physiological action. Digitalis acts as a sedative to an *overactive* and *irregular heart*, and as a tonic to a *weak and enfeebled heart*. But its proper employment should be in dilated enfeebled heart with feeble and irregular action. According to some writers it is contraindicated in *ramollissement* and *faturation* of the heart, and in *aortic regurgitation*, while it is especially beneficial in *aortic obstructive disease*.

That the slowing of the heart, with more powerful contractions and greater resistance to the blood current in the contracted arterioles produced by it, will render the drug inadmissible in a heart already enfeebled by fatty deposits, must be self-evident. *Slight muscular degeneration* is said not to contraindicate its use, providing there are otherwise strong reasons for its use. But when *aortic regurgitation* occurs, which is due to faulty action of the valves (*valvular insufficiency*), the heart is but relatively weak, and a stronger contraction is needed to force the current onward, and thus prevent, as far as possible, the valvular leakage. In the course, some hypertrophy exists here, but not enough to be compensatory. As to physiological effects, in *aortic stenosis*, it may produce death. M. Legrand states that, when given to persons in feeble health, it increases the contractile power of the capillaries, causing increased arterial tension, lowering the temperature of the body, diminishing the frequency of the heart beats, and relieving *congestions*. It has, in this manner as before stated, been of service in *pulmonary congestion*, *uterine* and *pulmonary hemorrhage*, and in *hemorrhoids*. In cases where the circulation is generally active, with small, frequent, but regular pulse, *aconite* is preferable to digitalis. "Digitalis is indicated where there is a diminution of vascular tension; if the cardiac palpitations are purely nervous without any modification of arterial tension, digitalis is of no value. Another indication for the use of digitalis is *œdema*, which shows an abnormal disposition of the cells to admit the fluid material of the blood into them. It should not be employed in

heart diseases of aged persons, among those heart diseases that have already attained to a period of complete and continued asystole, nor in excessive dilatation of the heart, various cardiac degenerations, and other persistent conditions of a manifest (extreme) hyposthenia" (Ferrand).

To sum up, digitalis is useful in the following conditions: In *structural heart lesions*, as *dilated heart with mitral incompetence*; in *mitral stenosis* and *regurgitation*, and in *dilated right heart with tricuspid incompetence*, and in relative or positive *debility of the cardiac muscle*. The mechanical trouble is a state of *ischæmia*, or lack of sufficient arterial blood in the left heart, while in the right heart and the entire systemic and pulmonic circulation there is venous stasis. Digitalis increases the power of the auricles and ventricles to empty themselves; prolongs the inter-contraction intervals, thus allowing the auricles sufficient time to more perfectly send the blood current into the ventricles. It restores and regulates a mechanical compensation or balance in the circulatory organs. The general symptoms leading to its selection are a weak, rapid, and irregular pulse, low arterial tension, cough, dyspnoea, pulsation of the jugular veins, a cyanotic countenance, deficient urination, the secretion being high-colored, and cedema.

Digitalis is contraindicated in simple compensatory hypertrophy, aortic stenosis, fatty or other degenerations of the heart muscle, and atheromatous or other structural changes in the arteries. As a rule it should not be employed in the heart affections of old age, or when dilatation is excessive, and particularly when the flabby state of the heart muscle is due to degenerative changes.

It was formerly believed and still the view is held by many, that the diuretic effect of digitalis is the result of its secondary action. If, however, the views more recently advanced, that it has also a special action upon the renal glomeruli be true, the reason for its well-earned reputation as a remedy in *dropsy* will be more apparent. Digitalis has long been known as an efficient remedy where the dropsical condition was dependent upon cardiac irregularities and upon renal congestion. When the trouble is cardiac in origin it relieves by strengthening the heart action and producing capillary contraction. When of renal origin, obstructing the circulation, it relieves at least the tension of the renal capillaries, thus lessening engorgement and bringing about absorption and diuresis. In general dropsy it is indicated by the distressing dyspnoea, especially when in the recumbent posture, fullness and pulsation of the jugulars, pale or dusky countenance, scanty and high-colored urine, and quick, feeble, fluttering, and irregular pulse. When known to be associated with the cardiac lesions in which digitalis is indicated, it seldom fails to remove the dropsical effusion. It relieves *chronic nephritis* by lessening vascular tension in the renal capillaries, and in *granular degeneration of the kidneys* it is said to benefit by lessening the proportion of solids excreted, while the quantity of fluid is increased. While of doubtful utility in *scarlatina*, it is very serviceable in the anasarca condition sometimes following that disease. *Rheumatism*, with threatened heart failure, is sometimes relieved by digitalis. Owing to its power of preventing erections, by limiting the supply of blood to the erectile tissues, it has proven itself of service in *nocturnal seminal pollutions*, particularly when the extremities are cold, the erections feeble, and the emissions oft-occurring.

The leaves, bruised and mixed with warm water, and applied upon the abdomen as a cataplasm, or the tincture mixed with warm flaxseed poultice, has been successful in *urinary suppression*. So great was the cutaneous absorption in one case that an enormous diuresis followed, producing death by exhaustion. Without doubt many of the failures from the use of digitalis in properly selected cases are due to the quality of the drug employed. A recent study of digitalin by competent observers shows, however, that it is unreliable in therapy and does not adequately represent the crude leaf. In fact, the crude drug in infusion is, without doubt, the best preparation of digitalis for use in medicine, and that no uncertainty as regards quality should exist, the best English digitalis should be employed. The dose of digitalis, in powder, is from $\frac{1}{2}$ to $1\frac{1}{2}$ grains, repeated every 4 or 6 hours; of the tincture, from 3 to 20 minims; of specific digitalis, 1 to 3 minims; fluid extract, 1 to 2 minims; infusion (see *Infusum Digitalis*), $\frac{1}{2}$ to 1 fluid ounce. The infusion should always be well shaken before administration, lest, in case of precipitation of digitalin, which has been thought to occur, an inordinate

quantity of the latter should be contained in the last dose administered. Weaker infusions than the official may be administered, and for diuretic purposes it should be remembered that its action is slow, sometimes not apparent until several days after administration. Consequently too much should not be given until its effects are produced, lest the cumulative effect should obtain. Of digitalin, from $\frac{1}{16}$ to $\frac{1}{8}$ of a grain in syrup, or in pill mass, may be given for a dose, if it be found desirable to use it—cautiously increasing to an amount not to exceed the $\frac{1}{8}$ of a grain.

Specific Indications and Uses.—Weak, rapid, irregular heart action, with low arterial tension; weak heart sounds; dusky countenance, jugular pulsation, cough, and dyspnoea; oedema; anasarca with scanty, high-colored urine; renal congestion. An antidote to aconite, but slow in its action.

Related Drugs.—*Coronilla scorpioides*. France. Cardot (1886) pronounces this leguminous plant an active heart poison. Its action is much like that of digitalis, both upon the heart and kidneys. Its effects, however, are more transient. A glucosid, *coronillin* ($C_{11}H_{16}O_5$), has been separated from it by Schlagdenhauffen and Reeb (1889). It is a yellowish powder, soluble in water, amyl alcohol, and acetone, slightly so in chloroform and ether. Treated with nitric acid, containing some cupric chloride, it produces a characteristic red coloration (*Amer. Jour. Pharm.*, 1891). If heated with hydrochloric acid (diluted) an amorphous, yellow resin (*coronillein*) is obtained; insoluble in water, but soluble in alcohol, chloroform, and acetone. It has no perceptible physiological action (*Amer. Jour. Pharm.*, 1889). Much uncertainty exists as to the size of the dose of this drug, one observer stating that $\frac{1}{2}$ grain is poisonous, while another recommends as high as 5 grains. It is suggested as a remedy for cardiac dropsy.

MAUWIN BARK.—Mozambique. The bark of a tree employed by the natives of eastern Africa as an "ordeal" poison. It resembles sassy bark and contains an alkaloid (*mauwinum*), obtained by E. Merck, in 1891. Alcohol, chloroform, and ether dissolve it. Its action is considered similar to, but more transient than that of digitalin.

Urechites suberecta, *Savannah flower*, *Yellow-flowered nightshade* (*Nat. Ord.*—Apocynaceae). West Indies. Violent emeto-catharsis with convulsions are the symptoms attributed to this plant, which is said to be used as a poison by the negroes of Jamaica. Two glucosids of the digitalis group are found in the plant: *Urechitin* ($C_{23}H_{34}O_8$) and *urechitoxin* ($C_{23}H_{34}O_9$). Small doses of the plant are said to depress the heart's action, and, in larger doses, nausea, vomiting, marked general depression, increased action of the skin, and slowing of the pulse, are attributed to it. Death is produced by cardiac paralysis. The fluid extract, in doses of from 2 to 10 drops, has been used in Jamaica in the treatment of *athenic fever*.

DIOSCOREA.—WILD YAM.

The rhizome of *Dioscorea villosa*, Linné.

Nat. Ord.—Dioscoreaceae.

COMMON NAMES: *Wild yam*, *Colic-root*, *Rheumatism-root*.

Botanical Source.—*Dioscorea villosa*, Linné. This is an herbaceous, slender vine, found throughout the United States, but more common in the central and southern portions. The stem is a smooth green twiner, about the size of a goose-quill, twining from the right to the left, over fences, bushes, etc. The leaves are symmetrical and heart-shaped, gradually tapering to a sharp, acuminate point, and are borne on leaf stalks from 2 to 4 inches long. The lower leaves are in whorls of 4 or 5, with intervals of from 6 inches to a foot between, while those on the upper part of the vine are irregularly alternate. The margins of the leaves are entire and wavy in the larger leaves. The veins are generally 9, quite prominent, and gradually diverge from the top of the leaf-stalk. The under side of the leaves is clothed with a thick pubescence. The flowers appear in June or July, are dioecious, very small, and greenish-yellow. The male flowers are in compound loose spikes, with from 3 to 5 slender branches; the perianth is 6-parted, sessile, flattened, and has, near the base, 6 minute stamens. The female flowers are placed at intervals of $\frac{1}{2}$ of an inch or $\frac{1}{2}$ an inch apart, in simple, drooping, axillary spikes, consisting each, of from 4 to 8 flowers. The ovary is sessile, slender, about $\frac{1}{2}$ of an inch in length, bearing at the summit a 6-parted, small perianth, and 3 short styles. The female flowers are succeeded by dry, brown fruit, which remains hanging among the limbs of shrubs in winter for some time after the herbaceous stems of the plant have perished. They are sharply 3-angled, and have 3 cells, each cell bearing 2 (or often, by abortion, 1) flat, membranous-winged seed.

Dioscorea villosa, Linné, var. *glabra*.—This appears to be a distinct variety, chiefly differing from the preceding in the entire dissimilarity of its rhizome.

The plant closely resembles the true wild yam in its general shape and in the structure of its leaves, flowers, and fruit. The leaves, however, are *entirely glabrous*, and are not covered with a short pubescence underneath. The two plants likewise appear to differ in their manner of growth, the *D. villosa* often growing in dense clumps, while the variety *glabra* is generally found isolated. From the specific name given to this plant by Linnæus, it is evident that he was possessed of a specimen of the pubescent kind (or the true wild yam), and we have ventured to apply the designation, var. *glabra*, to the variety distinguished by smooth leaves and knotty rhizome. Works upon botany recognize only *Dioscorea villosa*, but it has become necessary to classify the two rhizomæ of commerce. Considerable attention has been given by me to the plants, and without an exception the form of the rhizome was indicated by the pubescence of the under surface of the leaf. I am, therefore, led to hold to the foregoing distinctions until a better explanation is given (C. G. Lloyd).

History.—The rhizome of *Dioscorea villosa* is a favorite therapeutical agent among Eclectic physicians, who have advantageously used it for more than 60 years. It is known as *wild yam* and *colic root*. The first specimens employed were from the *Dioscorea villosa*, with pubescent leaves (Fig. 97), and now known as the *true wild yam*. About the year 1850, botanic druggists noticed the admixture by root-diggers of the rhizomæ represented by (Fig. 97, 1), and for a considerable time rejected it as an adulteration. The diggers insisted, however, that both "roots" were obtained from vines almost identical in appearance (although they can distinguish between them), and finally purchasers were compelled to accept them, more especially as the true rhizomæ became very scarce. The late Mr. H. M. Merrell, of Cincinnati, Ohio, to whom we are indebted for this information, stated that the first heavy shipments of the *false* "wild yam" root to Eastern houses were made about 1860, which article purchasers refused to accept, but after some correspondence, coupled with the fact that the true wild yam root could not at that time be obtained, the parties concluded to receive it. Since then the two rhizomæ have been sold indiscriminately, although but little of the original drugs to be found in the market. Eclectic physicians are aware of the difference between these rhizomæ, and refuse to use the "false" variety, insisting that it does not possess the medicinal properties, and can not safely be substituted for the "true." In this connection, we invite attention to the accurate engravings of each variety of the rhizomæ in Fig. 97.

The root loses its therapeutical virtues after the first year, and hence should be freshly gathered every year, and carefully dried. Water or alcohol extract its virtues. Several species of *Dioscorea* yield edible rhizomæ, generally known as "*yams*."

Description.—I. *DIOSCOREA VILLOSA*, *True wild yam*. The rhizome of *Dioscorea villosa* (Fig. 97, 2), appears in market in slender, contorted pieces, from $\frac{1}{4}$ of an inch to $\frac{1}{2}$ an inch in diameter, and often 2 feet in length. It is oval, being flattened above and below, as it creeps in a horizontal position beneath the surface of the ground. It seldom throws out branches, but occasionally little protuberances project from its sides being from $\frac{1}{4}$ of an inch to an inch in length, and about $\frac{1}{4}$ as large in diameter as the primary rhizome. They are rounding at the extremity, and seem to indicate an abortive attempt of the rhizome to throw out branches; but they do not send up the vine. Along the upper side of the rhizome are stem-scars, which are about $\frac{1}{2}$ of an inch apart. The epidermis is brown, thin, and scales

Fig. 97.

1. *Dioscorea villosa*, var. *glabra*.
2. *Dioscorea villosa*.

off, more or less, upon drying, especially when the rhizome is gathered in spring, but which is not the case with a good quality of it, when dug in autumn. The internal color of the dry rhizome is whitish, or slightly straw-colored, when gathered in the autumn, but it is often brown when collected early in the season; there is no bark to it. Under a magnifying glass the texture of a broken rhizome appears mealy and perforated with numerous woody bundles. Attached to the lower part of the rhizome, an abundance of strong, wiry-like fibers will be observed. *Dioscorea villosa* has one of the hardest of rhizomes, it being very difficult to pierce or crush. It has no odor, and but little taste beyond a slight acidity prolonged chewing.

II. *DIOSCOREA VILLOSA*, var. *glabra*; *False wild yam*.—The rhizome (Fig. 1) of this plant resembles that of *Collinsonia canadensis* more nearly than it does the true *D. villosa*. It is found as a rough clump of a pound or more in weight, fresh, thickly branched, each branch shooting from the side of the main rhizome at an angle inclining backward and upward. The branches almost touching each other, are as large as the rhizome, and are from 1 inch to 3 inches in length. Along their upper surface are numerous cup-shaped stem-scars, which are $\frac{1}{4}$ to $\frac{1}{2}$ of an inch in diameter, and so thickly inserted as to intrude upon each other. (The vine of the true *Dioscorea villosa*, upon the contrary, springs from the main rhizome). The diameter of the rhizome and of the ramifications is $\frac{1}{2}$ to $\frac{3}{4}$ of an inch, and the length seldom more than 6 inches. Internally, the rhizome resembles that of the true wild yam, while the lower portion is, in a manner, covered with stout, fibrous rootlets. The color is generally a very dark brown.

Chemical Composition.—The virtues of this drug appear to reside in an acrid resin, almost insoluble in water, but readily extracted by alcohol. The so-called *dioscorein* is not a definite principle of the rhizome, but is simply a dried solid extract, and to call it otherwise is a misnomer. Kalteyer (1888) found a substance closely allied to *saponin* in considerable quantity in the rhizome. Wild yam contains an abundance of starch.

Action, Medical Uses, and Dosage.—In former editions I have treated this agent an antispasmodic, and solely for the reason that it cures biliousness. And I can truly say that nearly all remedies have thus been classified, not from any positive knowledge of their action, but from the results following their administration. A change of classification based upon the known action of remedies is certainly desirable, and I am glad to observe that the attention of physicians has already been attracted in this direction. In the absence of any positive knowledge concerning the action of *dioscorea*, perhaps it would be better to say that it is a specific in bilious colic, having proved almost invariably successful in doses of $\frac{1}{2}$ pint of the decoction, repeated every half hour, or 5 drops. Specific *dioscorea* may be given in 5-drop doses every 5 minutes. No other medicine is required, as it gives prompt and permanent relief in the most severe cases (Prof. J. King). In fact it is not only of value in bilious colic, but in all forms of colic and other painful abdominal neuroses, and all forms of gastro-intestinal irritation. If it does not relieve in one hour, the medicine should be discontinued. It has allayed the pain incident to the passage of *biliary calculi* when given in full doses of gelsemium (Webster). It has also proved valuable in painful *morbus* attended with cramps, in *neuralgic affections*, in *irritable conditions of the nervous system*, especially when attended with pain or spasms, in *spasmodic hiccups*, in *obstinate and painful vomiting*, *gastralgia*, and in one case of *spasmodic asthma*. King effected a cure with it after several other means had failed. It will likewise allay nausea, also spasms of the bowels, and, combined with equal parts of bark of *Cornus sericea* in decoction, is eminently beneficial in the *nausea and vomiting of pregnancy*. This root appears to exert an action especially upon entire and irritable mucous tissues that become painful from spasmodic contractions of their muscular fibers; hence its value in *bilious colic*, in *painful dysenteric tenesmus*, in *dysmenorrhœa* the result of spasmodic irritation of the mucous membrane of the cervix uteri, and in *spasmodic irritations of the gastric mucous membrane* attended with pain, nausea, and vomiting. It is reputed useful in *indigestion with hepatic derangement*, in *chronic hepatic congestion*, and in the *chronic gastritis of drinkers*. It is also useful in *after-pains*. In ordinary cases the decoction of the root

be given in doses of from 2 to 4 fluid ounces, and repeated every half hour until relief is obtained. By many the infusion or decoction is considered preferable to the tincture. The tincture is said to be a valuable expectorant and diaphoretic, and in large doses produces emesis. Dose of the tincture, from 20 to 60 drops; specific dioscorea, 5 to 40 drops.

Specific Indications and Uses.—Bilious colic; other forms of colic with spasmodic contractions; yellow skin and conjunctiva, with nausea and colicky pains; tongue coated, paroxysmal abdominal pain, and stomach deranged; frequent small, flatulent, alvine passages; colic, with tenderness on pressure; sharp abdominal pain, made worse by motion.

DIOSPYROS.—PERSIMMON.

The bark and unripe fruit of *Diospyros virginiana*, Linné.

Nat. Ord.—Ebenaceæ.

COMMON NAMES: *Persimmon*, *Date-plum*.

Botanical Source.—This is an indigenous tree growing from 15 to 50 feet or more in height, its dimensions being larger at the South; the bark is rough and dark-colored; the branches alternate and spreading. The leaves are alternate, elliptic or ovate-oblong, abruptly acuminate, from 3 to 5 inches long, entire, smooth, shining, and glaucous beneath; the petiole, veins, and margin are puberulent. The flowers are obscure, pale, greenish-yellow, the fertile ones in axillary racemes, 1 to 3-flowered, the pedicels being shorter than the flowers; the sterile flowers are smaller and often clustered. Stamens 16 in the sterile flowers, 8 in the fertile, in the latter imperfect; the anthers of the sterile flowers are bilobed. The style is 2 to 4-cleft, and short; the stigma obtuse and spreading. The fruit is a round, golden-yellow berry, about an inch in diameter, containing a sweet and edible pulp, and from 6 to 8 hard, compressed seeds (W.—G.).

History.—This is a well known indigenous tree, growing in woods and fields from Rhode Island to the western states and southward, flowering from April to July, ripening its fruit in September and October. The fruit is edible after exposure to frost. The unripe fruit and the bark are very astringent, and are the medicinal portions of the tree. (For description of fruit see *Botanical Source*). A beer is sometimes made from the fruit, and the fruit is made into a bread with wheat bran, known as *persimmon bread*, and then kept for the purpose of making beer by means of fermentation with hops. The roasted seeds have been used in some portions of the South as a substitute for coffee.

Chemical Composition.—Water or alcohol extracts the virtues of the bark and unripe fruit. B. R. Smith found the unripe fruit to contain lignin, tannic acid, sugar, a little malic acid, and coloring matter; also, that when ripe the tannic acid almost disappears, while the sugar and malic acid become more abundant (*Amer. Jour. Pharm.*, 1846, 167). J. E. Bryan (1860) also found pectin present, and thought the tannin to be analogous to that of cinchona, catechu, etc., while others contend that it is identical with the tannin from oak and galls. The bark of persimmon was analyzed by F. E. Murphy (1889), and a crystalline body obtained by him from the ethereal extract investigated by Schleif (*Amer. Jour. Pharm.*, 1890). He found it to be free from nitrogen, and allied to the resins.

Action, Medical Uses, and Dosage.—Tonic and astringent. The bark has been used in *intermittents*, and both it and the unripe fruit have been beneficial in various forms of *disease of the bowels*, *chronic dysentery*, and *uterine hemorrhage*; used in infusion, syrup, or vinous tincture, in the proportion of 1 ounce of the bruised fruit to 2 fluid ounces of the vehicle, and $\frac{1}{2}$ fluid ounce or more given to adults, and a fluid drachm or more to infants. The infusion may be used as a gargle in *ulcerated sore throat*. When ripe the fruit is very palatable, and as it matures at a time when fruits are generally departing for the season, the cultivation of the tree would undoubtedly be a valuable accession to our autumnal fruits. A kind of brandy is obtained by distillation of the fermented infusion.

Related Species.—*Diospyros Kaki*, Linné filius, the *Chinese date-plum* or *Japanese persimmon*, is a native of China and Japan, and is cultivated in India. The fruit is of a bright-red color, about the size of an ordinary apple; when ripe, it is eaten by the Chinese, and when

dried, is made into sweetmeats. The bark is astringent, and probably resembles that of other species of *Diospyros*. The Japanese regard this persimmon as their best fruit, which they even eat before it ripens. When dried it resembles the fig. When fresh, and eaten with sugar and cream, it is said to be delicious. It is now cultivated in Florida (*U. S. Agr. Rep.*, 1890). J. Ishii, of Tokio, in 1895, found in the unripe fruit a considerable amount of tannin which disappears upon ripening; the pulp contains much dextrose and levulose, while the seeds, being free from starch, contain a soft white material, *mannane*, convertible into *mannose* by boiling with 5 per cent of sulphuric acid (*Proc. Amer. Pharm. Assoc.*, 1896, p. 574).

The bark of *Diospyros Kaki* has been advised as an astringent in chronic mucous affections, as in certain forms of *dyspepsia*, in *diarrhœa* and *dysentery*, in mucous diseases of the bladder and urethra, and as a local application in *leucorrhœa*, *gleet*, *chronic conjunctivitis*, and *catarrhal affections*. The fluid extract, diluted with water, may be applied locally, by injection, or by spray. By some physicians *kaki* is highly lauded as a remedy for *gastro-intestinal irritation*. Dr. J. W. Huckins (see Webster's *Dynam. Therap.*, p. 359), regards it as an excellent remedy for *dysentery*, *simple mucoid diarrhœa*, *chronic diarrhœa*, and *diarrhœa of typhoid fever*, quickly relieving pain, tenesmus, and thirst, and checking the discharges; he also praises it in *gastric catarrh*, *ulceration of the stomach*, or *bowels*, and in *catarrh of the rectum and colon*. A decoction of 1 or 2 drachms of *kaki* to $\frac{1}{2}$ pint of water, steeped $\frac{1}{2}$ hour and cooled, is employed in doses of 1 to 4 tablespoonfuls every 1 to 4 hours as required.

Diospyros obtusifolia, Willdenow; Mexico. Bark and leaves employed. Astringent tonic. *Diospyros embryopteris*, Persoon, or *Indian persimmon tree*, is found in India, Java, and neighboring tropical islands; but is not valued highly for its fruit, which is insipid. When green, they are very astringent, and are employed in tanning. The inspissated juice has been used in *diarrhœa*; it is thick and viscid, and has been employed in India as a preservative for coating fishing nets, and the seams of boats. The unripe fruit was admitted into the *Pharmacopœia of India* in the year 1868.

DIRCA.—LEATHERWOOD.

The bark of *Dirca palustris*, Linné.

Nat. Ord.—Thymelæaceæ.

COMMON NAMES: *Leatherwood*, *Moosewood*, *American mezezon*, *Wickopy*.

Botanical Source.—This indigenous shrub attains the height of 5 or 6 feet, having crooked, jointed, and spreading branches. The leaves are alternate, simple, entire, on very short petioles, oblong-ovate, or obovate, downy when young, smooth and membranous when fully grown, and pale underneath. The flowers are axillary, yellow, appear long before the leaves; when young they are inclosed within a small, hairy, bud-like involucre, occupying a sheath or cavity in the end of each flowering branch, usually in bunches of 3 together, with their peduncles cohering. Corolla none. Calyx funnel-shaped, $\frac{1}{2}$ inch long, with a contraction near the base and another in the middle. The stamens are 8 in number, much longer than the calyx, alternately a long and a short one, with rounded anthers. The ovary is ovate, placed obliquely, the style appearing to issue from one side; the style filiform, curved, longer than the stamens, and terminated by an acute stigma. The fruit is a small, oval, red or orange-colored berry, containing one seed (B.—W.).

History, Description, and Chemical Composition.—This shrub is more common to the northern and eastern states, being occasionally met with in the west. It inhabits marshy places, low swampy woods, flowering in April and May. The bark is the part used; it is very tenacious and fibrous, and hard to pulverize. It has a disagreeable odor, and a pungent taste, with considerable acrimony, producing ptyalism, which property it imparts to alcohol, and slightly to boiling water. It has been used for making ropes, thongs and baskets, and might be advantageously employed in the arts, for making paper, etc. The wood is white, soft, and very brittle. It has not been satisfactorily analyzed, though mucilage, an acrid resin, and bitter extractive have been found in it.

Action, Medical Uses, and Dosage.—The bark is acrid, rubefacient, and vesicant when fresh. From 5 to 7 grains of it cause great gastric heat and uneasiness, with emesis and catharsis. In contact with the skin it produces rubefaction, followed by blisters, and the sores it occasions are frequently difficult to heal, forming very indolent and obstinate ulcers. If chewed it causes salivation, with burning pain in the tongue, gums, etc., and has thus proved useful as an irritant in *paralysis of the tongue*, *toothache*, *facial neuralgia*, etc. Bigelow says, that a decoction of the bark may be used as a sudorific and expectorant, in the place of *senega*. The berries produce vomiting, and are said to be a narcotic poison.

DRACONTIUM.—SKUNK-CABBAGE.

The rhizome, roots and seeds of *Dracontium foetidum*, Linné (*Ictodes foetidus*, Tigelow; *Pothos foetida*, Michaux; *Symplocarpus foetidus*, Salisbury).

Nat. Ord.—ARACEÆ.

COMMON NAMES: *Skunk-cabbage*, *Skunk-weed*, *Meadow-cabbage*, *Polecat-weed*, *Fœtid ellebore*.

ILLUSTRATIONS: Millspaugh's *Amer. Med. Plants*, Plate 169; Meehan's *Native Flowers and Ferns*, Vol. I, Plate 15.

Botanical Source.—Skunk-cabbage is a perennial plant, having a large, abrupt root or tuber, with numerous, crowded, verticillate, fleshy fibers, which extend some distance into the ground. The spathe, which appears before the leaves, is ovate, turgid, various in width, cucullate, spotted and striped with purple and yellowish-green, the top acuminate and incurved, the edges folded inward, auriculate at the base and of length coalescing. The flowers are dull-purple, tetrandrous, numerous, and situated within the spathe on an oval or subglobose, short pedunculated spadix. The calyx consists of 4 fleshy, wedge-shaped, truncate sepals, having the top and edges inflexed. Corolla one. Stamens 4, opposite the sepals, with oblong filaments equal in length to the calyx; and oblong, exserted, 2-celled anthers. The style is 4-sided and tapering; the stigma minute and pubescent; the ovary roundish and concealed within the spadix.

After the spathe decays, the spadix continues to grow, and with it every part of the flowers except the anthers. When the fruit is ripe, the spadix has attained many times its original dimensions, while the calyx, filaments, and style are larger, very prominent and separated from each other. Within the spadix, at the base of each style, is a naked, round, fleshy seed, as large as a pea, white, tinged with green and purple, invested with a separate membranous coat, and with a prominent embryo situated in a depression at the top, and umbilicately attached to a large, solid perisperm. Sometime following the flowers, numerous large, crowded leaves appear, which are oblong, cordate, acute, and smooth, with numerous fleshy veins of a pale color, and are borne on long, channeled petioles, furnished with large, oblong sheaths, and are of bright-green color, and often 20 inches long by 12 broad (L.—G.—W.).

History.—This plant has been a troublesome one for botanists to dispose of. It has been variously annexed to *Ictodes*, *Dracontium*, and *Pothos*. Salisbury termed *Symplocarpus*, a name which is preferred by many botanists. It is indigenous, growing plentifully in various parts of the United States, in moist grounds, flowering in March and April, and maturing its fruit in August and September. It forms a roughened globular mass, 2 or 3 inches in diameter, in decay shedding the bulb-like seeds, which are $\frac{1}{2}$ to $\frac{1}{4}$ an inch in diameter, and filled with the angular, solid, fleshy embryo (G.). The whole plant has an extremely disagreeable odor, resembling the commingled odors of skunk and onions, which is most apparent when the plant is bruised, and which has given rise to the several names *Skunk-cabbage*, *Skunk-weed*, *Polecat-weed*, and *Meadow-cabbage*. The parts used are the rhizome, with its rootlets, and the seeds. The rhizome should be gathered soon after the appearance of the spathe, or after the seeds have matured in autumn. It has the unpleasant odor of the plant, and, when fresh, a persistent, acrid taste.

Description and Chemical Composition.—As found in commerce the drug is in somewhat cylindrical pieces, 2 inches or more in length, and about 1 inch in diameter, or, more commonly, in transverse slices, very much compressed and corrugated. Its color externally is dark-brown, and internally whitish, or yellowish-

Fig. 98.

Dracontium foetidum.

white. Drying lessens the odor as well as the acidity of the plant, and age and exposure dissipate them entirely, consequently the root should be renewed annually. The seeds have been used and preferred as being more energetic than the root. They have an exceedingly acrid taste, and emit the fetid odor of the plant only when bruised. They preserve their virtues longer than the root. The properties of this plant are chiefly owing to a volatile substance, which loses its activity by desiccation, and is completely volatilized by subjection to an increased temperature. Alcohol or water extracts its virtues, and the aqueous infusion should be made by displacement. As far as we can ascertain, the only analysis on record of *Symplocarpus fetidus* is that of Mr. Jos. M. Turner (*Amer. Jour. Pharm.*, 1836, Vol. VIII, pp. 1-10), who found the root to contain besides starch, fixed and volatile oils, "a peculiar substance, soluble in acids and precipitated by alkalies." In the seeds he found starch, gum, resin, albumen, fixed oil, wax, and coloring matter.

Prof. Bastin showed the starch of *Symplocarpus fetidus* to be so characteristic of the drug as to allow its identification in cases where it is used as an adulterant of commercial *Veratrum viride* (*The Apothecary*, 1893, p. 152).

Action, Medical Uses, and Dosage.—In large doses, according to Bigelow, skunk cabbage will cause sickness at stomach, vomiting, headache, dizziness, and impaired vision. In medicinal doses it is a stimulant, exerting expectorant, powerful antispasmodic, and faintly narcotic influences. Its action upon the nervous system is marked, relieving irritation, and it has a tendency to promote normal functional activity of the nervous structures. It has been successfully used in *asthma, whooping-cough, nervous irritability, hysteria, epilepsy, and convulsions during pregnancy and labor*; likewise in *chronic catarrh, pulmonary, and bronchial affections*. The powdered root or seed may be given in doses of from 10 to 40 grains, 3 times a day; but the most eligible mode of administration is a saturated tincture of the fresh root, of which 1 or 2 fluid drachms may be given for a dose. It enters into the composition of *Acetous Emetic Tincture, Compound Emetic Powder*, and several other old Eclectic preparations.

DROSERA.—SUNDEW.

The herb *Drosera rotundifolia*, Linné.

Nat. Ord.—Droseraceæ.

COMMON NAMES: *Sundew, Round-leaved sundew.*

Botanical Source.—Sundew is a low, small, perennial, herbaceous, aquatic plant, also called Round-leaved sundew, with a fibrous root, from which arises the leaves, which are radical, small, and nearly round, depressed, lying flat upon the ground, and abruptly narrowed into the spreading hairy petioles. The scapes are erect, 5 to 8 inches high, at first coiled inward, and bearing a simple raceme. The flowers are arranged on one side, very small and white; the sepals are 5, united at the base, and persistent; the petals 5 and convolute. The stamens 5; anthers adnate; styles 3 or 5, each deeply 2-parted. Ovary single. Capsule 3 or 5-valved and many-seeded. The seeds are spindle-shaped, and the coat loose and chaff-like (W.—G.).

Drosera rotundifolia.

History.—Sundew (*Ros Solis*) is a peculiar little plant, growing in Europe and this country, in bogs, and muddy shores of ponds and rivers, and flowering in July and August. It may be at once distinguished by the reddish glandular hairs with which the leaves are beset, and which are usually tipped with a small drop of a clammy fluid, appearing like a dew drop, glistening in the sun, this secretion being most abundant when the sun is at its highest, from which circumstance it derives its name. The long, shining red hairs of this plant form beautiful objects for the microscope, under which they are seen to consist of an immense number of minute cells, regularly arranged, and exhibiting a most gorgeous variety of brilliant colors. They are very irritable, slowly curved inward, and entrap insects within their reach; the fluid secreted from their points

also retains insects which settle upon it. The flowers only open in sunshine. The juice of the plant is bitter, acrid and caustic. The medicinal preparation is the tincture of the recent plant.

Chemical Composition.—Trommsdorf examined the juice of this plant (*Chem. Centralbl.*, 1833), finding in it a free organic acid, probably malic acid, organic salts, and a red coloring principle, which formed an insoluble compound with acetate of lead. Reess and Will believed the free acid to be a mixture of formic, propionic and butyric acids, and Hager thought it to be malic and citric acids combined. Lugan obtained from the juice of the plant a crystallizable acid insoluble in chloroform; besides, a greenish-brown resin, by successive treatment with ether and chloroform. It is soluble in both these solvents and possesses acrid properties. According to Stein's experiments (*Ber. d. Deutsch. Chem. Ges.*, 1879; also *Amer. Jour. Pharm.*, 1880, p. 12), the free acid in *Drosera intermedia* was identified with citric acid, which acid probably occurs in all species of *Drosera*. A ferment also seems to be present, capable of converting albuminous substances into peptones. Experiments of H. Büsgen (see *Amer. Jour. Pharm.*, 1885, p. 106) would demonstrate that the plants of *drosera* are capable of assimilating animal food.

Action, Medical Uses, and Dosage.—This agent appears to exert a peculiar action upon the respiratory apparatus, and its effects are best observed from the use of small doses. It is peculiarly adapted to dry, spasmodic, or explosive coughs, such as are met with in many cases of *whooping-cough* and *measles*—for the cough of the latter it being an almost absolute specific. The coughs met by *drosera* are those in which dryness of the air passages is marked, and there is irritation or even inflammation, and nervous irritation, particularly irritation of the base of the brain and of the parts supplied by the vagus. The special seat of most of the trouble seems to be centered in the larynx. Tickling in that organ, giving rise to spasmodic cough, is met by it, and while exceedingly useful in all coughs having the above characteristics, it appears to benefit best those cases associated with or following measles and whooping-cough. For the latter it may also be given as a prophylactic, and if the individual does contract the disease, the influence of the medicine will have been early obtained. Sanguinarine nitrate acts well with it in dry, tickling cough. It has been found essentially useful in *asthma*, *incipient phthisis*, *chronic bronchitis*, with dry, spasmodic cough, and *nervous* or *sympathetic cough*, whether from pulmonary, cardiac, or gastric disease. Two fluid drachms of the saturated tincture, or 1 drachm of specific *drosera*, may be added to 4 fluid ounces of water (or wine, if indicated), of which a teaspoonful may be administered every 3 or 4 hours. In former times it was considered a powerful aphrodisiac, and as a remedy to cure *intermittents*, *insanity*, and to promote *delivery*. The juice of the plant has been used as a local application for the cure of *corns* and *warts*. Dose, of the saturated tincture, 1 to 5 drops; specific *drosera*, $\frac{1}{2}$ to 5 drops.

Specific Indications and Uses.—Expulsive or explosive, spasmodic cough, with dryness of the air passages; whooping-cough; cough of measles; uncontrollable irritating cough.

DUBOISIA.—DUBOISIA.

The leaves of *Duboisia myoporoides*, Robert Brown.

Nat. Ord.—Solanaceæ.

COMMON NAMES: *Corkwood elm*, *Orungurabie*, *Ngmoo* (native names).

Botanical Source.—This is a large shrub found in Australia and New Caledonia. It has alternate, smooth, entire leaves, narrowed into a short leaf-stalk, which is articulated to the branches. The flowers are small, white, and disposed in large terminal panicles. The calyx and corolla are 5-parted, with obtuse lobes. The stamens are didynamous, with the rudiment of a fifth, and bear 1-celled anthers. The fruit is a small, black, 2-celled berry, which contains a few reniform, rough seeds. The genus *Duboisia* is intermediate between the natural orders *Solanaceæ* and *Scrophulariaceæ*, and was referred to the former by the older authors; Benthani, in the *Flora of Australia*, classes it with the latter, but more recent developments regarding a natural constituent (*duboisine*), seem to indicate that its true place is among the *Solanaceæ*.

History.—The honor of introducing this drug to the profession belongs to Dr. J. Bancroft, of Brisbane, Australia, who presented the plant to Baron von Mueller for botanical identification, and who, at his suggestion, experimented with it as a therapeutical agent, and presented the first paper on the subject to the Queensland Philosophical Society of Australia, in October, 1877. Shortly afterward, he (Bancroft) sent specimens of the plant to the Museum of the British Pharmaceutical Society. In March, 1878, Mr. E. M. Holmes read a paper before the society on *Duboisia myoporoides*, its botanical history, etc., and nearly at the same time, a communication appeared in the *London Lancet* from Drs. Ringer and Tweedy, detailing a line of experiments upon its therapeutical action, in which the previous report of Dr. Bancroft was corroborated in every particular. Shortly afterward, Gerrard, of England, and Petit, of France (see *Pharm. Jour. Trans.*, [3], Vol. VII, p. 787), almost simultaneously announced the discovery of an alkaloid called *duboisine* or *duboisina*. F. von Mueller and L. Rummell also announced their discovery of *duboisine* from *D. myoporoides* (*Jour. Chem. Soc.*, January, 1879, p. 32), but as their alkaloid is an oily, volatile base, its identity with *duboisine* is questionable.

Chemical Composition.—The chief constituent of this leaf, called *duboisine* by its discoverers, was found by Prof. A. Ladenburg to be identical with *hyoscyamine* ($C_{17}H_{23}NO_3$) (*Ber. d. Deutsch. Chem. Ges.*, 1880, p. 1257). The properties of *duboisine* are therefore described under *hyoscyamine* (see *Hyoscyamus*). Another isomeric alkaloid was obtained by Merck, called *pseudo-hyoscyamine*, forming yellowish needles of an acrid, bitter taste, soluble in alcohol and chloroform, slightly soluble in ether. Its melting point is 133° to 134° C. (271.4 to 273.2° F.), while *hyoscyamine* (*duboisine*), melts at 106° to 108° C. (222.8° to 226.4° F.) (Merck's *Index*, 1896).

Action, Medical Uses, and Dosage.—The action of *duboisia* upon man and animals is very similar to that of belladonna, *hyoscyamus*, etc. Dogs and cats to which it has been administered, almost immediately commence walking with difficulty, stumbling over the least obstacle as though they were blind, and falling asleep as soon as they are left at rest, having the pupils largely dilated; these results also followed its introduction into the system by hypodermatic injection. Large doses internally, or by subcutaneous injection, occasion large pupillary dilatation, dryness of the mouth and throat, increase the number of pulsations, and give rise to general debility, vertigo, and cephalalgia; the results are the same with man as with animals. The alkaloid, *duboisine*, produces similar effects. The sulphate of this alkaloid, subcutaneously injected in large doses, occasions a sort of intoxication, mental derangement, pupillary dilatation, incoordination of muscular motion, relaxation of the vesical and anal sphincters, and an increased temperature at first, succeeded by a very marked diminution.

As an internal remedy, neither the shrub nor its alkaloid (except as *hyoscyamine*) have come into general use. Used in this manner, *duboisia* will be found to possess properties similar to those of belladonna and its congeners. *Duboisine*, and its sulphate, are more commonly employed in this country, principally in ocular therapeutics; it has been found by Drs. Wecker and Galezowski, of Paris, to be a prompt and unirritating mydriatic, the mydriasis being accompanied with paralysis of the ciliary muscle, and consequently an absolute loss of accommodation. The mydriasis produced does not appear to annoy the patient, nor to last as long as when occasioned by atropine; nor does the employment of the agent give rise to the intense conjunctival irritations (follicular conjunctivitis and eczema of the lids) so often following the application of atropine. It may be employed in all *maladies of the eyes* in which atropine is indicated, being contraindicated in glaucomatous conditions, and in diseased conditions of the fundus. From 2 to 4 grains of the sulphate of *duboisine* are dissolved in 1 fluid ounce of water, and of this solution from 2 to 5 drops may be instilled into one or both eyes as required; the mydriatic effect commences in a few minutes. The solution of the sulphate of *duboisine* has likewise been successfully employed, by hypodermatic injection, for checking the pathological *sweatings common to phthisis*, etc., and also as an antidote to *poisoning by mushrooms*, antagonizing the paralyzing effect of muscarine on the heart. It is reputed palliative in *exophthalmic goitre*. The dose to be used will differ with various individuals, from the $\frac{1}{16}$ or $\frac{1}{8}$ to $\frac{1}{4}$ grain. The beginning dose should rarely exceed $\frac{1}{8}$ grain. For ophthalmic use 1 to 4 grains to 1 ounce of distilled water. Care should be had in its use, as occa-

sionally untoward symptoms have been produced by reduced applications (see also *Atropinæ Sulphas*, *Belladonna*, and *Hyoscyamus*).

Specific Indications and Uses.—A substitute for atropine as a mydriatic, and to check colliquative sweating; antagonizes muscarine; mushroom poisoning.

Related Species.—*Duboisia Hopwoodii*, F. von Mueller. This is the Australian *Pitury*, also known as *piturie*, *pedgery*, *pitchiri*, *pitchery*, and *bedgery*. It has long been known that the natives of Central Australia use the leaf of some shrub in order to invigorate themselves, after long marches, or when they are desirous of undergoing great fatigue, as during a battle. This leaf is used as a masticatory by the Australians in a manner similar to that of the coca leaves by the South Americans. It is asserted that when the natives chew pitury "in company," the quid is passed from one to another until all are satisfied, when one of the number preserves it by sticking it behind his ear (Maiden, *Australian Useful Plants*). Dr. Bancroft, of Brisbane, in 1872, made some physiological experiments with authentic specimens of pituri; yet the source of the drug was unknown until 1877, when Baron von Mueller identified it from a specimen of the leaves of the plant submitted to him by Mr. W. O. Hodgkinson; accordingly, the pitury is *Duboisia Hopwoodii*, F. Mueller, a shrub found sparingly "from the Darling River and Barcooto to West Australia." But little is known of this shrub, as it grows in a country difficult of access. Staiger is probably the first who isolated from *Duboisia Hopwoodii* piturine, an alkaloid with which the "duboisine" of F. von Mueller and F. Rummel (see above), is most probably identical. A. W. Gerrard, in 1880, independently discovered the alkaloid piturine in this plant (*Pharm. Jour. Trans.*, 1880). When fresh it smells like nicotine, but when older has a smell of pyridine. Its vapors affect the mucous membranes and cause violent headache. Some authorities (e. g., Petit, *Jour. Pharm. Chim.*, 1879, p. 338), consider piturine identical with nicotine. Prof. Liversidge, however, points out some differences in their reactions, but otherwise they are quite similar (*Amer. Jour. Pharm.*, 1881, p. 357). Piturine ($C_{12}H_{13}N_2$), was obtained by him in the amount of 1.0 and 2.4 per cent. It is a colorless alkaloid, volatile at ordinary temperatures, changing to yellow and brown rapidly when exposed to air and sunlight. It is soluble in water, alcohol, and ether, is slightly heavier than water, and forms salts with acids, which, with oxalic acid, are capable of crystallizing. Its salts gradually lose the alkaloid by evaporation. Piturine is reported to antagonize the action of muscarine on the heart, but not so promptly as atropine. Dr. Bancroft states that this drug arrests the respiration of animals, and thus causes their death. The action of pitury is essentially different from that of *duboisia*. Applied to the eye, it first contracts, and then widely dilates the pupils; internally, small doses contract the pupils, while large doses produce a wide dilatation. Faintness, giddiness, trembling, pallor, quickened and shallow breathing, increased heart action, and sweating, are induced by it, and if the dose be large, drowsiness, ptialism, spasmodic muscular twitching, and spasmodic rigidity of the limbs are among its effects.

DULCAMARA (U. S. P.)—DULCAMARA.

"The young branches of *Solanum Dulcamara*, Linne" (U. S. P.).

Nat. Ord.—Solanaceæ.

COMMON NAMES: *Bittersweet*, *Woody night-shade*, *Violet-bloom*, *Scarlet-berry*.

ILLUSTRATIONS: Bentley and Trimen, *Med. Plants*, 190; Woodville, *Med. Bot.*, 133.

Botanical Source.—*Bittersweet*, or *Woody night-shade*, is a woody vine, having a woody root, with a shrubby, flexuous, thornless, and branching stem, several feet in length; with an ashy-green bark on the stem and large branches. The leaves are alternate, acute, and generally smooth; the lower ones ovate or cordate; the upper ones more or less perfectly hastate, and all entire. The flowers are purple, drooping, and are borne on branching peduncles from the side of the stem, in spreading, cymose clusters. The calyx is very small, purplish, acute, persistent, and 5-parted. The corolla is rotate, purple, with 5 reflexed segments, and 2 round, green spots at the base of each segment. The filaments are short; the anthers erect, opening by pores at the apex, yellow, and converging into a cone. Ovary roundish; style filiform; stigma simple and obtuse. The fruit is a scarlet, oval, juicy, bitter, and poisonous berry, the seeds of which are many, plano-convex, and whitish (L.—W.—G.—B.).

History and Description.—*Bittersweet*, also known by the names of *Violet-bloom* and *Scarlet-berry*,

Solanum Dulcamara.

is common to both Europe and this country, growing on moist banks, around dwellings, and in low, damp grounds, about hedges and thickets, flowering in June and July. Its berries are ripened in autumn, and hang upon the vines for several months. The parts used in medicine are the roots and twigs, the latter only being official. The berries when eaten have certainly produced serious consequences, though considered by many to be harmless. The twigs should be collected in the autumn, after the dropping of the foliage; they have an unpleasant odor, which is lost by drying; and their taste is bitter, followed by some sweetness and a slight acidity. The dried twigs found in commerce are in pieces varying in length, having a greenish-gray epidermis, a light wood, and a very light and spongy pith. They impart their properties by infusion to boiling water, and also to diluted alcohol; long boiling impairs their medicinal activity. The *U. S. P.* describes *dulcamara* as follows: "About 5 Mm. [$\frac{1}{4}$ inch] or less thick, cylindrical, somewhat angular, longitudinally striate, more or less warty, usually hollow in the center, cut into short sections. The thin bark is externally pale greenish, or light greenish-brown, marked with alternate leaf-scars, and internally green; the greenish or yellowish wood forms 1 or 2 concentric rings. Odor slight, taste bitter, afterwards sweet"—(*U. S. P.*).

Chemical Composition.—Two proximate principles have been obtained from *Solanum Dulcamara*: *Solanine*, an alkaloidal principle, discovered by Desfosses, in 1820, in the berries of *Solanum nigrum*, and (1821) in the leaves and stems of *S. Dulcamara*; and *dulcamarin*, its bitter-sweet glucosid, was first isolated in pure form by E. Geisler, in 1875. Probably it is identical with a substance previously named *picroglycion* by Pfaff, and *dulcarin* by Desfosses (1821). It was again obtained by Biltz (1841), and later by Wittstein, who named it *dulcamarin*.

Peschier (1828) demonstrated that solanine existed in the berries of *dulcamara* in even larger quantity than in the leaves and stem; it also occurs in the sprouts of our common potato (see *Solanum tuberosum*, *Related Species*) and in various other Solanaceæ, e. g., the tomato plant (G. W. Kennedy, *Amer. Jour. Pharm.*, 1873), etc. Desfosses obtained it from the ripe berries of the black night-shade (*Solanum nigrum*) by expressing the juice, adding ammonia, washing the precipitated alkaloid with cold water, and crystallizing from alcohol, after purifying with animal charcoal. Fresh sprouts of potatoes furnish it in greatest abundance.

Solanine ($C_{25}H_{45}NO_{10}$, Kraut; $C_{22}H_{37}NO_{11}$, Hilger) occurs either amorphous, in minute prisms, or in feathery crystals, having a bitter, somewhat acrid taste. Solanine fuses at $235^{\circ}C.$ ($455^{\circ}F.$). It is soluble in warm amyl alcohol, which abstracts it completely from alkaline solutions; is less soluble in boiling alcohol, still less in cold alcohol, considerably less in ether (1 in 4000), and requires 8000 parts of boiling water for solution. The solution of solanine in alcohol tends to gelatinize upon cooling; the solution in amyl alcohol possesses this property in a pronounced degree (Dragendorff). Solanine has an alkaline reaction and combines with acids to form salts. Dilute mineral acids decompose solanine slowly at ordinary temperatures, and more rapidly at boiling heat, into sugar and *solanidine*, another alkaloid which is soluble in cold ether and hot alcohol, but hardly soluble in water (Zwenger and Kindt, also Gmelin, 1859). O. Bach (1873) recommends as a test for solanine and solanidine, the behavior of these substances towards a mixture of equal volumes of concentrated sulphuric acid and alcohol; a trace of these alkaloids causes the appearance of a rose-red, then cherry-red color, which lasts for 5 or 6 hours, and is not interfered with by the presence of large quantities of morphine (*Amer. Jour. Pharm.*, 1873).

Dulcamarin ($C_{22}H_{34}O_{10}$) was obtained by E. Geissler (*Archiv. der Pharm.*, 1875, p. 293) from the stems of *dulcamara*, by digesting the aqueous infusion with animal charcoal until the peculiar, bitter-sweet taste was removed, washing the charcoal with water and abstracting by means of alcohol. After purification of the bitter-sweet extractive (by using of its lead compound), pure *dulcamarin* was obtained free from nitrogen (Wittstein's *dulcamarin* contained nitrogen), as an amorphous yellow substance, possessing the characteristic, bitter-sweet taste of the plant in concentrated form. It is soluble in alcohol and water (30 parts) and in acetic ether, but it is insoluble in ether, chloroform, and petroleum ether. Diluted sulphuric acid splits it into *dulcamaretin*, a tasteless, resinous substance, and sugar. Solanine is poisonous.

Action, Medical Uses, and Dosage.—Prof. Caylus, of Leipsic, who has made some careful experiments with solanine, as well as with the twigs of dulcamara, states that an extract of the twigs is from 5 to 10 times more active than the twigs, and solanine is 30 times more powerful than this extract. He considers the plant and its active principles to possess poisonous properties, which may prove fatal in large doses. All these preparations, when administered internally, cause renal congestion, and occasionally an augmented urinary secretion of an albuminous nature; they exert a depressing or paralyzing influence upon the respiratory nervous system, cause increased but enfeebled cardiac action, tetanic spasms of the thoracic muscles as well as those of the extremities, and increase the sensitiveness of the cutaneous nervous system; they exert no direct influence upon the brain, stomach, or bowels. He believes they act more particularly on the spinal cord and medulla oblongata, and recommends the acetate of solanine, in doses of $\frac{1}{2}$ to 1 grain, in *pulmonary maladies*, attended with spasm or irritation (*Ann. de Thér.*, 1859, p. 24).

Solanum Dulcamara is a mild narcotic, diuretic, alterative, diaphoretic, and discutient. In large doses it causes dryness and heat with stinging pain in the fauces, accompanied with thirst, sickness at stomach, vomiting, diarrhoea, prostration or syncope, and spasmodic twitchings. With some persons it depresses the action of the heart and arteries, and causes a moderate degree of lividity on the hands and face. The head usually feels heavy and dizzy, and a cutaneous erythema may be developed. It is reputed antaphrodisiac, and has proved beneficial in *mania* attended with powerful excitement of the venereal functions. On the other hand, it is said to occasion venereal desires, and to induce heat and itching of the external female parts, attended with strangury.

Dulcamara is a valuable remedy in most *acute troubles*, brought on by *colds*, and in *chronic skin affections* of a pustular, vesicular, or scaly character. It has been chiefly used in syrup or decoction in *cutaneous diseases*, *syphilitic diseases*, *rheumatic* and *cachectic affections*, *ill-conditioned ulcers*, *scrofula*, *indurations from milk*, *leucorrhæa*, *jaundice*, and *obstructed menstruation*. It is of more benefit in scaly cutaneous diseases than in others, as in *leprosy*, *tetter*, *eczema*, and *porrigo*, and especially in combination with guaiacum and yellow-dock root.

Dulcamara is a remedy for *catarrhal troubles*, resulting from cold or suspended cutaneous action. Here the fractional doses should be employed. *Suppression of the menses*, with headache, nausea, and chilly sensations, when the flow has been arrested by cold, is a case for its exhibition. *Dyspnoea*, *cough*, and *pain in the chest* produced by exposure, are relieved by small doses. *Catarrhal headache*, from acute colds, and *nasal catarrh* are both benefited by bitter-sweet, which is also a remedy for *retrocession of eruptions*, and to primarily develop tardy eruptions. Owing to its kindly action on the stomach and its influence in aiding secretion and excretion, it is a valuable alterative and should have a more general use. In *vesical catarrh*, aggravated by dampness, it has given good results. The same is true of *catarrhal diarrhoea* of children, and *acute and chronic rheumatism* in those who are much exposed or who dwell in cold or damp quarters. *Nymphomania* and *satyriasis* were successfully treated with it by Dewees. *Pundental itching* and *stitching pains* have been relieved by it in small doses. Large doses have produced these troubles. Dr. Scudder suggests a trial of the drug in "small doses in those cases of chronic disease in which the circulation is feeble, the hands and feet cold and purplish, with fullness of tissues and tendency to œdema" (*Spec. Med.*, 246). Equal parts of the twigs, yellow-dock root, and stillingia made into a syrup, form a valuable preparation for *scrofulous affections*, as well as *syphilitic*. Externally, in the form of ointment, it is employed as a discutient to *painful tumors*; also as an application to some forms of *cutaneous disease*, *ulcers*, and *erysipelatos affections*. Dose of the decoction or syrup, 1 or 2 fluid ounces; of the extract, from 2 to 5 grains; of the powdered leaves, from 10 to 30 grains; specific dulcamara, fraction of a drop to 30 drops. Small doses act best. The decoction is prepared from 1 ounce of fresh twigs and sufficient water to produce, after boiling for 15 minutes, 1 pint of decoction.

Specific Indications and Uses.—Scaly skin affections; acute disorders due to colds and dampness; deficient capillary circulation in the skin; diminished cutaneous action with urinous odor; coldness and blueness of the extremities; full tissues with tendency to œdema.

Related Species.—Several other species of *Solanum* appear to possess medicinal power—among them are: *Solanum tuberosum*, Linné; *Common potato*. An extract of the herb, *Solanum tuberosum* (common potato), has been found useful in *chronic rheumatic affections, gastric and intestinal spasm, cough, etc.*, in the dose of from $\frac{1}{4}$ of a grain to 1 grain. Some practitioners have, however, employed it in these affections, and in very large doses, without observing any influence whatever. Probably cultivation, soil, climate, season, etc., exert some influence upon the medicinal powers of the plant. The potato itself has been eaten raw, either with or without vinegar, in cases of *scurvy*, and with good effect; occasionally it has caused narcosis, and slight purgation. Both raw and cooked the potato makes an excellent poultice. Considerable potassium hydroxide may be procured from potato-stalks; and if they be gathered while the plant is in flower, and passed through an oil mill, the juice obtained is said to form a handsome yellow dye. Wackenroder obtained *solanine* from potato sprouts. The green fruits and the herb of the potato plant have also been shown to contain solanine and its allied bases, *solanidine* and *solanine*. In 1887, Dr. George Kassner demonstrated that weighable quantities of solanine will develop in injured potatoes when stored in a cellar (*Amer. Jour. Pharm.*). Traces of mydriatic alkaloids (hyoscyamine, etc.) have even been observed in *Solanum tuberosum* and allied species.

Lycopersicon esculentum, Millspaugh; (*Solanum Lycopersicum*).—*Tomato*, or *Love-apple*, like the potato, came originally from South America. Its fruit contains several acids (citric, oxalic, and malic acids having been shown to be present), a thick, adhesive, brownish, resinous-like substance, and the seeds probably contain an alkaloid. It is much used as an article of food in the United States, and is supposed to exert a healthy influence upon the liver and biliary organs. The leaves have a heavy, disagreeable odor, and contain oil, extractive, and *solanine*, which has been obtained from all the herbaceous portions of the plant (Kennedy, *Amer. Jour. Pharm.*, 1873). Most of the *Solanums* are nutritive, or possess medicinal virtues.

Solanum Pseudo-capsicum, *Jerusalem cherry*.—A handsome, erect, dwarf tree-like shrub, a native of Mauritius, and bearing large scarlet berries. Poisonous. On account of the resemblance of the fruit to cherries, children are liable to be poisoned by them.

Solanum Melongna (or *esculentum*), *Egg-plant*.—This plant yields an elongated, purple fruit known as the *egg-apple*, *binjal*, or *aubergine*. It does not possess the agreeable properties of tomato, but when properly prepared is much esteemed as a vegetable.

Solanum nigrum, Linné; *Garden night-shade*, *Night-shade*.—*Solanum nigrum* is a fetid, narcotic, bushy herb, with a fibrous root and an erect, branching, angular, herbaceous, thornless stem, 1 or 2 feet in height. Leaves undivided, ovate, toothed, and waved, smooth, lengthened out at the base, almost always with the lamina perforated and the margin erose; as if gnawed by insects. Umbels from the intermediate spaces between the leaves, solitary, peduncled, simple, downy, nodding. Flowers white or pale-violet, with a musky scent; anthers yellow. Berries globose, black, about the size of peas (L.—W.—G.). The *Garden*, or *Black night-shade*, is found growing along old walls, fences, and in gardens, in various parts of the United States, flowering in July and August. Another species, the *Solanum virginianum*, is abundant in this country. It has an erect, prickly stem; pinnatifid leaves, prickly on both sides; divisions sinuate, obtuse; margin ciliate; calyx prickly, and flowers blue, or whitish. The leaves of these plants are the parts employed, and yield their properties to water, alcohol, or fixed oils.

Solanum nigrum is narcotic and sedative, and produces, when given in large doses, sickness and vertigo. One to 3 grains of the leaves infused in water, will, it is said, produce a copious perspiration, and often purge on the next day. They have been used in *cancer, scurvy* and *scrofulous affections*, being applied locally as a cataplasm, or in ointment, and also exhibited in small doses internally. *Solanine*, which was first obtained from this species by Deafoses, in 1820, exists in it more abundantly than in the *S. Dulcamara*, to which it is somewhat analogous in medicinal properties, with more active and energetic narcotic virtues. The berries are poisonous, causing torpor, burning in the stomach, fever, nausea, stupor, and insensibility; though this is denied by M. Dunal, of Montpellier. The plant is employed in the form of ointment only, as a discutient.

Solanum paniculatum, *Jerubeba*.—Brazil. Considerably used by Brazilian physicians in *anemia, liver disorders, amenorrhœa, vesical catarrh, and spleen disorders*. It is regarded tonic, alterative, antiperiodic, antisyphilitic, antiblennorrhagic, and drastic. The leaves, fruit, and root are employed both externally and internally. It is considered a good laxative to overcome chronic constipation. *Jerubeba*, an alkaloid, is contained in the root and fruit (F. V. Greene, *Amer. Jour. Pharm.*, 1877, p. 506).

Solanum bacciferum.—A variety of this plant yields the toxic *summer berries*, from the eating of which several cases of poisoning have been reported. Another variety of the same species is said to be harmless, and its fruit is employed by the natives of Jamaica.

Solanum Jacquinii, Willdenow (*Solanum xanthocarpum*, Schrader).—A drug of considerable repute in India, where it is valued as a diuretic, expectorant, and sialagogue. It is used in Bengal for *dropsy*, and, smoked in a pipe, gives relief in *toothache*. *Catarrhal fevers, cough, and asthma* are among the conditions said to be benefited by it (*Dymock, Mat. Med. Western India*).

Lycium umbrosum, Humboldt and Bonpland. *Nat. Ord.*—*Solanaceæ*. South America. *Lycium Afrum*, Linné.—North Africa. The leaves of this and the foregoing species are employed in infusion for the relief of numerous skin affections, particularly *erysipelas*.

Lycium vulgare, Dunal (*Lycium barbarum*, Linné); *Matrimony vine*.—Indigenous to Mediterranean Europe and is found in the United States, both wild and cultivated. Its flowers are of a dull, purple-green hue. The leaves and bark have a sweet, followed by a faintly bitter, acrid taste. *Lycine* ($C_8H_{11}NO_2$), in deliquescent, white, prismatic crystals, was obtained by Husemann and Marmé, in 1863, from the leaves and branches, the former yielding the larger amount of

alkaloid. Its identity with Scheibler's *betaine* (Liebrich's *oxynurine*), from the juice of beet-root, was subsequently (*Archiv. der Pharm.*, 1875, p. 216) proven by Husemann. According to the latter, it does not pre-exist in the plant, but is developed during the process of obtaining it—i. e., heating in the presence of hydrochloric acid. Alkaloidal mydriatic principles, like those from belladonna, have been detected in this plant by E. Schmidt and others (see *Amer. Jour. Pharm.*, 1880, pp. 13 and 492).

ECHINACEA.—ECHINACEA.

The root of *Echinacea angustifolia*, De Candolle.

Nat. Ord.—Compositæ.

COMMON NAMES: *Narrow-leaved purple cone-flower*, *Purple cone-flower*, *Cone-flower*, *Black sampson*.

Botanical Source.—*Echinacea angustifolia* is an herbaceous plant, the thick, black, pungent root of which sends up from year to year, a slender, sometimes somewhat stout stem, bristling with hairs, and from 2 to 3 feet high. The leaves (see illustration), which are 3-veined and hispid-pubescent, vary in shape from broad lanceolate to lance-linear. At the base they become slender, and the lowermost have short petioles. The involucre consists of about 2 rows of lanceolate, scaly bracts. As the flower develops the disk is at first concave, but as the growth progresses it becomes ovoid, the receptacle taking on a sharply conical form. The linear-lanceolate, chaff-like bracts of the receptacle are firm, remain permanently attached, are boat-shaped and concave, and become narrowed into a stiff, spine-like crisp, extending beyond the disc-flowers. The ray-flowers are narrow, and from 1 to 2 inches long. They are rose or purple, and drooping or pendant, and, while withering, are yet persistent. They are generally "imperfectly styliferous." Rarely these ray-flowers or ligules are white. The disc-florets are cylindraceous, presenting fine, erect teeth, and the tubular portion upon which the stamens are inserted, is scarcely a tube proper, but merely a ring. The fruit consists of acutely 4-angled akenes (1-seeded, dry, indehiscent pericarps, tipped with the remains of the style), of a firm, tough, yet cork-like texture. They are beset with a thick, crown-like papus, which is extended somewhat into triangular teeth.

History.—Conspicuous among the remedies introduced within recent years, echinacea undoubtedly takes the first rank. As with all new remedies, it has suffered the usual over-estimation, and the exaggerated claims made for it led Prof. Lloyd to view it with suspicion for a long time. Prof. H. T. Webster (*Dynam. Therap.*), was the first to give an extensive, though sectional, account of the therapy of the drug. Though now a well-known drug, echinacea stands peculiarly alone in being essentially a new remedy. Many remedies which have lately been introduced can be traced back for years, and some of them for centuries, as having at some time occupied a place in either domestic or professional practice, but our ancient scientific works are silent concerning this species of echinacea. Gray, in his *Synoptical Flora of North America*, published some years ago, wrote: "Used in popular medicine under the name *black sampson*," but since he refers to the plant as "*black sampson*," a name applied to *Echinacea purpurea*, it may be accepted that he referred to that drug. A careful search through the large number of works upon domestic medicine, herbals, medical botanies, and the so-called "irregular" works upon practice, contained in the Lloyd Library, failed to reveal even a mention of *Echinacea angustifolia* as a medicinal agent. In this connection, the following from the pen of Mr. C. G. Lloyd, who identified the drug first used by Dr. Meyer and Dr. King, will serve to distinguish between black sampson and *Echinacea angustifolia*:

"*Echinacea purpurea*, Moench, is a plant growing in the eastern states from Pennsylvania west. It was introduced in King's *Dispensatory* under the name of *Rudbeckia purpurea*, and the common name black sampson. *Echinacea angustifolia*, De Candolle, is an entirely different plant, found only in prairie regions, and not occurring east of the prairie regions of Illinois, and has never been used under the name black sampson. There is no mention of it in medical literature preceding the paper of Drs. Meyer and King." The first notices concerning echinacea are from Eclectic physicians, and the drug is, from start to finish, an Eclectic medicine.

Echinacea angustifolia is an indigenous plant of the composite order, growing chiefly in the western states, from Illinois to Nebraska, and southward from Missouri to Texas, thriving best in rich prairie soil. That which grows in marshy places is of inferior quality. It has also been stated that it grows in rocky and sandy soil. The plant, however, which is abundant in Kansas, Nebraska, and neighboring localities, is not mentioned by P. A. Rydberg in his recently published *Flora of the Sand Hills of Nebraska* (Contributions to the Botanical Nat. Herbarium, Vol. III, No. 3, 1895). The plant blooms from June to August. *Echinacea* is sometimes known in Kansas as *nigger-head*, a name derived from the shape and somber hue of its fruiting head. The scientific appellations derived from physical features of the plant, and are therefore descriptive. The generic term *Echinacea*, is derived from the Greek *echinos*, meaning hedgehog or sea-urchin, referring to the spiny, hedge-hog-like fruiting head; while the name *angustifolia*, comes from the two Latin words, *angustus* (narrow) and *folium* (leaf), contrasting thereby this species with the other forms of *Echinacea*, being the narrow-leaved species.

The introduction of echinacea into professional practice is due conjointly to Dr. H. F. C. Meyer, of Pawnee City, Neb., and the late Prof. John King. The former had, for many years (since 1870), been using the plant without knowing its botanical position. In a letter to Prof. King (see *E. M. J.*, 1887), in 1886, he communicated to the latter his uses of the drug, as he had employed it for 16 years. He claims for the remedy were based upon the conclusion that it was "an antiseptic, modic and antidote for blood-poisoning." The enthusiastic doctor had been using it in a secret mixture with wormwood and hops, which he had denominated "Meyer's Blood Purifier." Among his claims for it was its antidotal action against the poison of various insects, and particularly that of the rattlesnake. He stated that he even allowed a rattler to bite him, after which he bathed the place with some of the tincture, took a drachm of it internally, and laid down to sleep, and upon awakening all traces of swelling had disappeared! Prof. King wrote: "He (Dr. Meyer) kindly offered to send the writer a rattler 8 feet long, that the antidotal influence of the tincture upon dogs, rabbits, etc., bitten by a serpent, might be tested; but having no friendship for the reptile, and being unaccustomed to handling this poisonous ophidian, the generous offer was respectfully declined."

The following range of affections were those in which Dr. Meyer claimed success for this remedy: Malarial fever, cholera morbus, cholera infantum, boils, internal abscesses, typhoid fever (internally and locally to abdomen); ulcers, sore throat, old ulcers, poisoning from rhus, erysipelas, carbuncles, bites and stings of bees, wasps, spiders, etc.; in nasal and pharyngeal catarrh, hemorrhoids, various fevers, including typhoid, congestive, and remittent; trichinosis, nervous headache, acne, scrofulous ophthalmia, milk crust, scald head, and eczema; also colic in horses. Subsequent use of the drug has in a measure substantiated seemingly incredulous claims of its introducer, for it will be observed that many of these conditions were such as might be due to blood depravation, or to non-introductions from without the body—the very field in which echinacea is known to display its power.

In the autumn of 1885, Dr. Meyer sent to Prof. J. U. Lloyd a quantity of the root, desiring the latter to enlighten him as to its botanical name. At the same time he expressed Dr. King a quantity of the tincture. Prof. Lloyd, questioning the claims of Meyer, wrote to him that he could not name the plant from the root alone, whereupon the latter shipped another quantity of the root. It was allowed (September 28, 1886) by a specimen plant, which Mr. Curtis G. Lloyd identified as *Echinacea angustifolia* of De Candolle (see paper by Prof. Lloyd in *Echinacea*, in *E. M. Jour.*, Aug., 1897).

Prof. King, appearing to have more faith than Prof. Lloyd in the possibilities of the new drug, took an active interest in it, and by experimenting extensively was soon convinced of its great value. His use of it led him to report success in obstinate naso-pharyngeal catarrh; in rheumatism (one case being of the articular variety); in cholera morbus and cholera infantum; in chronic ulcers of the skin (one case of which was complicated with an eczematous eruption of years' standing); also in painful chronic hemorrhoids, vaginal leucorrhoea with ulceration

ie os uteri, poisoning from poison ivy, and stings of wasps and bees, with very extensive swelling. Dyspepsia, with pain and great distress, aggravated by parking of food, and long resisting treatment, also yielded to it. Goss (*Chicago Medical Times*, 1888), who became interested in the drug, praised it as a remedy for mad dog bites, chronic catarrh, chronic ulcers, gonorrhoea, and syphilis. Dr. A. Arker, of Wilber, Neb., also reported success with it in an apparently hopeless case of septicæmia. Then followed the reports of Dr. Hayes (see below), whose statements did much to obtain general recognition for the drug.

Description, Chemical Composition, and Preparations.—The root of echinacea varies in thickness, from that of an ordinary lead pencil to that of the little finger. The deep-brown or reddish-brown epiderm is shrunken and wrinkled longitudinally, and is often disposed in spiral folds upon the subdermal portion of the root. The woody portion, as seen upon a transverse section (see illustration of root), is composed of medullary rays, separated by a greenish, pulp-like substance. When broken the dried root exhibits a grainy and apparently rotten aspect. When chewed the root, if of good quality, imparts at first a sweetish taste, subsequently becoming acrid and pungent, and finally leaving a persistent tingling sensation, followed by a peculiar numbness of the tongue and fauces, seemingly intermediate in character between that produced by aconite and cocaine. It has been compared to the pricking produced by prickly ash, but is essentially different, lacking the peculiar aromatic qualities of the latter.

Tincture of echinacea is transparent, and of a reddish-brown color. It mixes well with water, as does also the fluid extract, which gives at first no appreciable precipitation in that fluid. The preparations chiefly employed by Eclectic practitioners, and from which the medicinal value of the agent has been determined, are specific echinacea and ECHAFOLTA. The latter is simply a purified preparation of echinacea, free from coloring matters and extraneous substances, such as chlorophyll, extractive, and other "plant dirt." Much of the root collected has little medicinal value. This is due not to poorly kept and cured roots alone, but chiefly to the locality in which it grows. Much of the drug collected in the marshes and lowlands east of the Mississippi is of this negative quality. The best quality of root comes from the prairie lands of Nebraska (J. U. Lloyd in *E. M. J.*, 1897, p. 27). The experience of the writer is to the effect that few drugs vary more in quality than crude echinacea.

According to Prof. Lloyd, who has made a complete pharmacological study of this drug, extending over a period of 13 years (since 1885), the best menstruum for the preparation of either the fluid extract or common tincture of echinacea is a mixture of alcohol 4 parts, and water 1 part. His investigations of echinacea reveal the presence of minute quantities of an alkaloid, which is devoid of color and unimportant so far as its medicinal qualities are concerned. His earlier analyses failed to show the existence of this principle. The characteristic principles of the root are those substances linked to an acid organic body of a resinous character, nearly, if not quite colorless, and possessing, in an altered degree, the persistently acrid qualities of echinacea—so intensely that it is distressing to the taste, even in very small amount, when pure. The stinging sensation affects the tip of the tongue for hours. But small quantities of it are present, even in the best root—"less than $\frac{1}{2}$ to 1 per cent." (Adapted in part from article by Prof. J. U. Lloyd in *E. M. Jour.*, August, 1897).

Action, Medical Uses, and Dosage.—As a therapeutic agent echinacea is often used both internally and locally at the same time; therefore in this article the internal and external uses will not be given separately, but collectively. And inasmuch as echafolta is a name given to distinguish a purified form of echinacea, the remarks concerning the one are equally applicable to the other, except in important surgical cases, where greater cleanliness is desired, when echafolta is to be preferred.

Under the older classification of remedies, echinacea would probably be classed as an antiseptic and alterative. Strictly speaking, it is practically impossible to

Fig. 102.

Dried root.
 $\frac{1}{2}$ natural size.

classify an agent like echinacea by applying to it one or two words to indicate its virtues. The day is rapidly approaching when these qualifying terms will have no place in medicine, for they but inadequately convey to our minds the therapeutic possibilities of our drugs. Especially is this so with regard to such terms as alterative, stimulant, tonic, etc. If any single statement were to be made concerning the virtues of echinacea, it would read something like this: "A corrector of the deprivation of the body fluids," and even this does not sufficiently cover the ground. Its extraordinary powers—combining essentially that formerly included under the terms antiseptic, antifermentative, and antizymotic—are well shown in its power over changes produced in the fluids of the body, whether from internal causes or from external introductions. The changes may be manifested in a disturbed balance of the fluids resulting in such tissue alterations as are exhibited in *boils, carbuncles, abscesses, or cellular glandular inflammations*. They may be from the introduction of serpent or insect venom, or they may be due to such fearful poisons as give rise to *malignant diphtheria, cerebro-spinal meningitis, or puerperal* and other forms of *septicæmia*. Such changes, whether they be septic or of devitalized morbid accumulations, or alterations in the fluids themselves, appear to have met their antagonist in echinacea. "*Bad blood*," so called, *asthenia*, and *adynamia*, and particularly a *tendency to malignancy* in acute and subacute disorders, seem to be special indicators for the use of echinacea.

Outside of the claims made for this remedy by its introducer, which included many of the conditions for which it is now valued, it first attracted general notice as a remedy for *septicæmia*, in which malady it appeared to promise more than any remedy previously in use. The reports of Dr. Hayes (*E. M. J.*, 1888, pp. 68, 142) gave an impetus to the use of the drug in this direction; since which time physicians, whose statements are valued, have lauded it as a remedy in various forms of blood-poisoning. Thus it has been successfully employed in *injuries complicated with septic infection*. A crushed hand, thought to be beyond aid, with the intolerable stench of putrid flesh, was saved by the application of echinacea. It has given equally satisfactory results in alarming cases of *venom infection*, with great depression, from the *bites of the rattlesnake, tarantula and other spiders*, and from the *stings of scorpions, bees, wasps, etc.* Prof. Webster, among others, speaks highly of its action in slow forms of *cerebro-spinal meningitis*, using it as the basic remedy (in connection with other indicated drugs), because of its sedative virtues, controlling, as he believes, the vascular area concerned in the nutrition of the cerebro-spinal meninges, and for its effects upon the general circulation. The cases benefited were those characterized by a slow, feeble pulse, or at least a pulse not appreciably quickened, with the temperature scarcely elevated, and cold extremities. The evidences of cerebral disturbances were erratic. Headache, with a peculiar periodical flushing of the face, even to the neck, was present, and associated with these symptoms, dizziness and profound prostration. Prof. Webster was the first, we believe, to employ the remedy in this affection. He asserts that as a stimulant to the capillary circulation, no remedy is comparable with it, and that it endows the vessels with a recuperative power or formative force, so as to enable them to successfully resist local inflammatory processes due to debility and blood deprivation.

While clinical evidence is strong in support of the curative action of echinacea in *diphtheria*, the writer can not but feel that in some instances, at least, the reports have been based upon mistaken diagnoses, and upon non-malignant cases. He is forced to this view from a liberal use of the drug in several cases of a malignant type, in which it utterly failed to accomplish the results desired. Non-malignant forms of diphtheria tend to recovery, and we should be careful about endorsing remedies as curatives in such cases, lest we bring discredit upon a good remedy by making sweeping claims for it which can not be substantiated when the drug is put to a test in the severer forms of the disease. Nevertheless, in these non-malignant cases it appears to expedite convalescence.

In the various forms of *tonsillitis* it has given better results, particularly in the necrotic form, with dirty-looking ulcerative surfaces. It comes well endorsed as a remedy for that malignant form of *quinsy* known in some of the western states as "*black tongue*." Echinacea will contribute much to the cure of various *catarrhal affections of the nose, naso-pharynx*, and other portions of the *respiratory tract*.

It is specially indicated by ulcerated and fetid mucous surfaces, with dusky or dark coloration, and a general debilitated habit. Many patients who have taken echinacea for other purposes have remarked its beneficial effects upon *catarrh*, from which they were suffering at the same time. *Chronic catarrhal bronchitis* and *fetid bronchitis* have been signally benefited by echinacea, and it has done that which few remedies can accomplish, *i. e.*, it has overcome the stench of *pulmonary gangrene*, and, if given early, it is asserted to avert a gangrenous termination in pulmonic affections. A case of *typhoid pneumonia* reported by Shelley (*Med. Gleaner*, 1894) with a "jet-black coating of the tongue," evidencing sepsis, improved rapidly under echinacea, in about 2-drop doses every 3 hours.

Echinacea is a good appetizer, and improves digestion. The writer has used it with good results in *fermentative dyspepsia*, with offensive breath and gastric pain as prominent symptoms, which was also aggravated upon taking food. It is also efficient in *duodenal catarrh*, and other forms of *intestinal indigestion*, with pain and debility. Few remedies are as efficient in *ulcerative stomatitis*, and in *nursing sore-mouth* it is asserted to be promptly curative. It has been praised in *diarrhœa*, *cholera morbus*, *cholera infantum*, and *dysentery*, all of the semi-inflammatory type, with a tendency to malignancy. Applied externally and given internally, it has been of service in aborting *typhlitis* and *perityphlitis*.

Echinacea has been prominently mentioned as a remedy for *fevers*. In the *eruptive fevers*, as *measles*, *chicken-pox*, and *scarlet fever*, it has received some praise, especially for its control over the catarrhal phases of the former, and its influence in masking the odor and controlling the pain of the scarlatinal angina. The fevers, however, in which it has accomplished the best results are of the *typhoid* and *typho-malarial types*, as well as in *sympathetic fevers* from septic infection and rheumatic attacks. Notwithstanding that it has been recommended as one of the best antimalarial remedies, it appears to exert but little influence over periodicity. Prof. King reported signal failure in every case of *ague* in which he gave it a trial. Others, however, speak of it as a remedy for *malaria* when of an asthenic character. Possibly in such conditions it might prove of value, as the fevers in which it has proved so successful have been chiefly characterized by *adynamia*. Very likely its usefulness here depends more upon its influence over the asthenia than upon the miasmatic poison. However, Dr. Snyder, of Cameron, Mo., a good authority, contends that it is an excellent remedy for *chronic malaria*, a personal use of it having first convinced him of its value. The doctor has not, however, given us the special cases to which it is adapted. *Epidemic influenza (la grippe)* is occasionally ameliorated by echinacea, and in all such cases, with great debility, it assists materially in securing a good convalescence.

Puerperal fever, due to septicæmia, yields somewhat to echinacea with potassium chlorate and other indicated remedies; yet, in some cases it is inadequate to check the disease unless a thorough curetting of the womb, to insure against the absorption of imprisoned fragments of placenta or unhealthy discharges, be first resorted to. Frequently this procedure alone, with a free use of hydrogen dioxide solution as a douche, is sufficient to cure, but a marked debility often persists. It is this debility that is so pronouncedly benefited by echinacea, and in two instances the writer has thought that the high temperature was averted, and the weakened system greatly sustained, by the liberal use of echinacea, until curetting had been accomplished. Others have been more fortunate in the use of the drug, giving it the credit of being the main agent in accomplishing cures. Its internal and local use is recommended. Hayes commends it in "*mountain fever*," an affection often mistaken for typhoid fever.

Echinacea is in some respects a remedy for *pain*. It relieves the pain of *erysipelas*, and contributes largely to a resolution of the swelling when extensive, tense, and of a purplish-red hue. It is reported to have relieved the pain of *cancerous growths*, particularly when involving the mucous membranes, as *cancer of the fauces*. Prof. Farnum calls attention to the wonderful rapidity with which the odor of carcinoma is overcome by echinacea. He strongly recommends it as an application for cancer, and relates a case of *mammary cancer* long held in check by it. He also advises its internal administration in *cancerous cachexia*. So great is the confidence placed in this agent by our foremost surgeons that they have been content to use it with sterilized water to cleanse and dress, after operations,

discharging tubercular abscesses, gangrene, empyema with gangrene of the lung, abscess of the breast and testicle (Farnum). Prof. L. E. Russell uses *echinacea* as a preventative of sepsis, giving it internally previously to operation to act as an intestinal antiseptic, and, locally, as a corrective, to dress any wound showing signs of sepsis, and as a wash in abdominal and pelvic operations into which any organ has discharged septic contents. *Phlegmonous sore-throat*, *sores*, *erysipelas* with sloughing phagedena, *dissecting or surgical wounds*, *phlegmonous*, *dolens*, *dermatitis venenata*, and *pus cavities* should be treated with *echinacea*, both locally and internally. A most remarkable case came under the care in which a high fever with marked adynamia, associated with the treatment of cellular abscesses and a hemorrhagic diarrhoea, yielded to *echinacea*. *Rhus aromatica*. Other medicines did but little good until these remedies were brought into use. The abscesses were of a non-active variety, somewhat painful but not excessively so; they numbered about 10 or 12 at any given time in various parts of the body. The alvine discharges were passed involuntarily when kept under control by the fragrant sumach. The boy, whose age was 4 years, lingered in this condition for over 2 months. *Echinacea* surely kept the child alive, for whenever the dose, which was 10 drops every 3 hours, was suspended the symptoms were greatly exaggerated. In spite of his low condition and very unsanitary surroundings, recovery took place rapidly, as soon as the symptoms subsided.

Echinacea is highly endorsed as a topical dressing for *malignant erysipelas*. *Painful mammitis* has been very successfully treated with it, and, used as an anodyne, it relieves the pain and inflammation in *gonorrhoea*. Several physicians have used it in *syphilis*, and declare it a good remedy for that disease, but it seems like claiming too much. It is, however, like *Thuja*, efficient in allaying pain and healing the ulcers, particularly of the mouth, throat, and tongue, in *syphilitic*. Dr. Snyder extols *echinacea* as an efficient remedy for *gonorrhoea*. It acts admirably in *purulent salpingitis*, contributing toward a cure and allaying the distressing pain. Evidence is abundant, concerning its value in *leucorrhoea* with offensive discharges; and Webster reports it as valuable in *erythema*, *erysipelatosus vulvitis*, being especially effective in that form affecting small children. *Echinacea* is a remedy for *eczema*. It is adapted to chronic cases, sticky or glutinous exudations associated with asthenia and general debility. Liberal doses should be administered for a prolonged period. A striking case, which had been diagnosed as *psoriasis*, resulting from vaccination, came under the care of Prof. Ellingwood, of Chicago. A shedding of the hair and a diffuse disease, with loss of the nails and thick skin from the palms and soles, followed by a destructive iritis of the left eye and corneal ulcer of the right. Prospects were fair for a fatal termination. Perfect recovery, with the exception of the loss of the left eye, followed the use of liberal doses of *echinacea*, begun with syrup of iodide of iron and phospho-albumen.

Droopy after scarlatina is said to have been cured by *echinacea*. As the condition usually tends to a spontaneous cure it is difficult to determine how any remedy contributes to such a result. Likewise *echinacea* has been recommended to prevent (!) *hydrophobia*. How one can prevent a result of this kind from a dog bite, and especially as the very existence of that so-called disease is denied by many, is not clear. Like many other new remedies *echinacea* has been reported curative in *smallpox*. It appears to have mitigated many of the symptoms of *tubercular phthisis*, and renders expectoration easier in "stone" or "grinder's" consumption. It would be no great surprise if this remedy should prove effective in impressing a tubercular diathesis, thereby preventing action in consumption.

The dose of either specific *echinacea* or *echinacea* ranges from 1 to 5 larger doses (even 60 drops) may be employed, but small doses are generally efficient if frequently repeated. They may be given in water or syrup, and glycerin, as: *R Echinacea*, flzj to flzij; water, q. s., flziv. *Mix.* Spoonful every $\frac{1}{2}$ or 1 hour in acute cases; every 3 or 4 hours in chronic cases. If these preparations are to be dispensed in hot weather, or are to be used in alimentary gastro-intestinal disorders, the substitution of 1 ounce of glycerin for 1 fluid ounce of the water is advisable. For external use both preparations

be employed, though in point of cleanliness *echafolta* is to be preferred. Solutions of from 1 to 60 per cent strength may be applied by means of a saturated compress every 2 hours, or oftener, if necessity demands.

Specific Indications and Uses.—To correct fluid depravation, "bad blood," tendency to sepsis and malignancy, as in gangrene, sloughing and phagedenic ulcerations, carbuncles, boils, and various forms of septicæmia; foul discharges, with weakness and emaciation; deepened, bluish or purplish coloration of skin or mucous membranes, with a low form of inflammation; dirty-brownish tongue; jet-black tongue; tendency to the formation of multiple cellular abscesses of semi-active character, with marked asthenia. Of especial importance in typhoid, septicæmic and other adynamic fevers, and in malignant carbuncle, pulmonary gangrene, cerebro-spinal meningitis and pyosalpinx. *Echafolta* is advised as a cleansing wash in surgical operations, and to annul the pain of and to deodorize carcinomata.

Related Species.—*Rudbeckia laciniata*, Linné; *Thimbleweed*. This plant, also known by the names of *Cone-disk sunflower* and *Tall cone-flower*, is a tall, showy, indigenous perennial plant, with a round, glabrous, stem, 3 to 8 feet in height. Leaves alternate, smooth or roughish; lower ones pinnate, with from 5 to 7 cut or 3-lobed leaflets, petiolate; upper ones irregularly 3 to 5-parted; lobes ovate-lanceolate, pointed. Flowers large, terminal; pappus crenate; chaff truncate and downy at the tip. Rays 1 or 2 inches long, oblanceolate, bright-yellow, spreading or drooping. Disk oblong-conical and columnar in fruit, greenish-yellow (G.—W.). This plant grows in various parts of the United States, in damp places, low thickets, edges of swamps and ditches, etc., flowering from July to September. It was introduced into Europe from America and cultivated in Paris early in the seventeenth century (see *Amer. Jour. Pharm.*, 1872, p. 107). The whole herb is recommended to be used. It has not been investigated chemically. It imparts its properties to water. Thimbleweed is a valuable diuretic, tonic, and balsamic. Useful in many diseases of the urinary organs, and highly recommended in *strangury*, *Bright's disease* (?), and wasting or *atrophy of the kidneys*. Dose of the decoction, *ad libitum*.

Echinacea purpurea, Mönch (*Rudbeckia purpurea*, Linné), variously called *Red sunflower*, *Comb-flower*, or *Purple cone-flower*, has a thick, black root, with branched, sulcate, smooth, or rough stems, 3 to 5 feet in height. Leaves alternate, 4 to 8 inches long, and about $\frac{1}{2}$ as wide, rough, with short, stiff bristles; lower ones broad-ovate, attenuate at base, 5-nerved, veiny, long-petioled, remotely-toothed; cauline ones lanceolate-ovate, acuminate, nearly entire. Heads large, solitary, on long peduncles. Disk thickly beset with the stiff, pointed, brown chaff. Rays from 15 to 20, 2 or 3 inches long, dull-purple, pendulous, bifid. This plant is common to the western prairies and banks, and is found also in the southern states, flowering from July to September. The root is very pungent to the taste, and has been popularly used in medicine under the name of *Black sassafras*. It is stated to have been employed with much benefit in *syphilis* (W.—G.). Both of the above plants deserve a full and thorough investigation from the profession. From all that I have been able to learn, the latter plant is equal to stillingia in medicinal efficacy (King).

Bouvardia triphylla, *Trompaila*.—Mexico. Stem and small branches an aboriginal remedy for *hydrophobia* (A. J. P., 1874).

Acerates decumbens.—New Mexico. Reputed specific for *snake-bites* (W. J. Wilson, M. D.).

ELASTICA (U. S. P.)—INDIA-RUBBER.

"The prepared milk-juice of various species of *Hevea* (Nat. Ord.—Euphorbiaceæ), known in commerce as *Para rubber*"—(U. S. P.).

SYNONYMS: *Caoutchouc*, *Gum elastic*, *Gummi elasticum*.

Botanical Source and History.—*Caoutchouc*, as it exudes from the trees, is a milk-like emulsion, wherein globules of *caoutchouc* proper are suspended in a gummy solution. It is produced by several plants chiefly of the natural orders, *Euphorbiaceæ*, *Apocynaceæ*, *Urticaceæ*, *Asclepiadaceæ*, and *Artocarpeæ*. The finest quality of rubber, that known as *Para rubber*, comes from the Amazon district, and is produced by the *Heveas*. The *Hevea guyanensis*, Aublet (*Siphonia elastica*, of Persoon; *Jatropha elastica*, Linné filius) or *Syringe-tree*, of Brazil, furnishes a portion of the species that are official in the U. S. P. This tree generally averages about 65 feet in height, with a diameter varying from 30 to 40 inches. Frequently the trunk reaches 40 or 50 feet in height before branching. In collecting rubber, the natives fasten a small, swallow-nest-shaped, glazed dish around the base of the tree by means of clay; then, by means of a hatchet, sever the bark immediately above it, and the milky sap immediately exudes, and is collected in the dish below. Twenty trees yield, daily, about 2 pints, continuing this amount for some

months. The most favorable period for extracting it is from April to November, during dry weather; the trees having to be wounded afresh every day. Some allow it to coagulate in a small, square box, but this method requires several days with subsequent slicing and pressure, to remove air and water; and some form it into bottles, tubes, etc., by dipping a mold of clay, fastened to the end of a stick, into the fresh juice, and immediately afterward holding it in thick smoke, produced by the combustion of oleaginous seeds. When the first layer has properly solidified, it is dipped again, and so continued until a sufficient thickness has been obtained. The smoke coagulates the milk, and exposure for some time to the sun hardens it. A small quantity of alum, or the addition of acids or salt solutions, accelerates the coagulation of the milk, while ammonia has a contrary effect, and is useful when the milk is required to be kept for some time in a liquid state.

Other South American grades, more or less inferior to Para caoutchouc are known commercially as *Pernambuco*, *Maranhão*, and *Bahia caoutchouc*, and are derived mainly from *Hancornia speciosa*, Gomez, an apocynaceous plant. Very large quantities of rubber are furnished by the *Landolphias*—*L. florida*, Benthams; *L. gummifera*, Lamarck, and *L. ovariensis*, all climbing, apocynaceous plants of West Africa; while in East Africa rubber is yielded by *Landolphia Petersiani* and *L. Kirkii*, and various species of *Vahea* in Madagascar. Other plants of the same order yielding *Borneo caoutchouc*, are the *Urceola elastica*, Roxburgh; *Urceola esculenta*, Benthams (*Chuvannesia esculenta*, DeCandolle), and other species from the Malayan Islands and India. The *Willughbeia edulis*, Roxburgh, and other apocynaceous plants yield the *Chittagong* variety. A kind of rubber is derived from *Urostigma Vogelii*, Miquel (*Nat. Ord.*—*Artocarpeæ*) of Liberia in West Africa; *Ficus indica*, Linné, and *Ficus religiosa*, Linné, yield an inferior caoutchouc.

The *Ficus elastica*, Roxburgh (*Urostigma elastica*, Miquel), is the chief source of East India caoutchouc, one variety being called *Assam rubber*. It has a trunk from 2 to 2½ feet in diameter, and from 40 to 60 feet high. The leaves are alternate, approximated, 3-foliate, articulate at the top of a long slender stalk, convex below, furrowed above, and swelled at its base; the leaflets are smooth, oval, acute, green above and cinereous beneath. The flowers are monœcious. Calyx 5-cleft. The fruit is oblong, greenish, 3-cornered, broadest at base, trilocular, each loculus opening with 2 valves. The seed is ovate, brownish, variegated with black, with a thin, brittle testa, and a sweet, nut-like, pleasant kernel. It is frequently cultivated as a hot-house plant.

Ceara rubber is the product of *Manihot Glaziovii*, Mueller, native of the Rio de Janeiro district. This Brazilian species, unlike the others of that country, thrives in dry situations. Good qualities are also obtained from the following South American species: *Hevea brasiliensis*, Mueller; *Hevea discolor*, Mueller, both yielding Para rubber; *Castilloa Markhamiana*, Collins, and *Castilloa elastica*, Cervantes. The export of rubber from the city of Para (at the mouth of the Amazon River), in the year 1893, exceeded 42,000,000 pounds. An instructive, exhaustive, and admirably illustrated article on rubber and its industry in South America, with a long list of rubber-yielding plants, classified according to their botanical and geographical origin, from the pen of Prof. H. H. Rusby, is to be found in the *Druggists' Circular*, 1894, p. 173. This valuable paper is too extensive to permit of condensation in our pages, and we commend the original article to persons interested in the subject. Efforts are being made to cultivate caoutchouc-yielding plants in various parts of the world; the chief difficulty with regard to *Hevea*, according to Prof. Rusby, seems to lie in the great length of time required (from 12 to 35 years), to bring the tree to a proper condition of productiveness. In Lagos, on the west coast of Africa, *Kickxia Africana*, Benthams (an apocynaceous plant, the seeds of which have become known as an adulterant of strophanthus seeds), is being cultivated with success, over 580,000 pounds having been exported during the first half of the year 1895. This plant has advantages over the *Landolphias* on account of the climbing habits of the latter, which make cultivation difficult (G. M. Beringer, *Amer. Jour. Pharm.*, 1896, p. 212, from *Kew Bulletin*, 1895).

Description.—Caoutchouc is black when coagulated by smoke, but when pure it is in thin, transparent layers, of a pale-yellow color, destitute both of taste and smell. Upon melting and subsequent cooling it remains in a semi-

fluid, adhesive state, undergoing very little change for years, if protected from the action of light, but when exposed to the action of diffused daylight, in the air, it gradually absorbs oxygen, and becomes converted into an inelastic, viscid mass, soluble in alcohol. It is described by the Pharmacopœia as follows: "In cakes, balls, or hollow, bottle-shaped pieces, externally brown to brownish-black, internally brownish or of lighter tint; very elastic; insoluble in water, diluted acids, or diluted solutions of alkalies; soluble in chloroform, carbon disulphide, oil of turpentine, benzin, and benzol. When heated to about 125°C . (257°F .), it melts, remaining soft and adhesive after cooling. Odor faint, peculiar; nearly tasteless. When pure, or nearly pure, India rubber floats on water"—(U. S. P.). It is insoluble in alcohol, softens and swells up by long boiling in water, but resumes its former state on exposure to the air, and is soluble in pure ether, most fixed and volatile oils, and coal-tar naphtha, the latter and oil of turpentine being technically convenient solvents. Hot alcohol and wood alcohol cause it to soften and swell. An excellent solvent for caoutchouc is a mixture composed of 6 parts of alcohol and 94 parts of sulphide of carbon. Its solutions in ether, oil of turpentine, and coal-tar naphtha, by evaporation, leave the gum in an elastic state, and on this principle water-proof cloth is made; the same is said to be the case with its solution in the oils of lavender, sassafras, and cajuput. The fixed oils, in dissolving it destroy its elasticity. Under exposure to heat, caoutchouc first melts and then distills, yielding a mixture of several oily liquids, all of which, as well as pure caoutchouc itself, are hydrocarbons. Atmospheric air, ammonia, hydrochloric and diluted sulphuric acids, exert no influence upon caoutchouc. Rubber tubing, it is said, may be prevented from becoming brittle by keeping it under water, which must be changed from time to time.

Chemical Composition.—India rubber is a hydrocarbon having the general formula $(\text{C}_{10}\text{H}_{16})_x$. It is therefore, to be considered a polymer of terpene ($\text{C}_{10}\text{H}_{16}$). Upon destructive distillation it yields oily substances, collectively called *oil of caoutchouc* (*caoutchoucine*), besides carbonic acid, carbon monoxide, hydrochloric acid, etc. This oil, when subjected to fractional distillation, may be separated into two fractions, one of low and the other of high boiling points. From the former, a hydrocarbon, *isopren* (C_5H_8), was isolated by Greville Williams (1860), having a specific gravity of 0.622, and a boiling point of 37°C . (98.6°F .). Bouchardat (1875) succeeded in obtaining from this oil, by polymerization, oils of higher boiling point, and the composition $\text{C}_{10}\text{H}_{16}$; and he even succeeded in obtaining artificial caoutchouc from *isopren*, which he therefore considers to be its basic principle. From the high boiling fraction Himly (Liebig's *Annal.*, Vol. XXVII, p. 40), isolated the hydrocarbon *caoutchin* ($\text{C}_{10}\text{H}_{16}$), which has a specific gravity of 0.654, and boils at 171°C . (339.8°F .). For a description of substances further evolved from India rubber, see Husemann and Hilger, *Pflanzenstoffe*, p. 511.

Caoutchoucine, or *oil of caoutchouc*, is said to be the lightest fluid known, and yet its vapor is denser than the heaviest of the gases. Mixed with alcohol, caoutchoucine dissolves all the resins, especially copal and India rubber, at ordinary temperatures, and it speedily evaporates, leaving them again in the solid state. It mixes with oils in all proportions, and but for its price would be valuable for the solution of resins in the manufacture of varnishes, and to replace turpentine for liquefying oil paints. Being very volatile it must be kept in closed vessels.

VULCANIZED INDIA RUBBER.—When caoutchouc in sheet-form is immersed in a bath of fused sulphur, heated to 121.1°C . (250°F .), it gradually takes up from 12 to 15 per cent of its weight of sulphur, but without undergoing any change in its chemical or physical properties; but if it be then heated for a few minutes to about 150°C . (302°F .), it produces the elastic *vulcanized India rubber*. The same vulcanized condition can also be produced either by kneading the India rubber with sulphur, and then exposing it to the necessary temperature; or by dissolving the India rubber in any known solvent, as turpentine, previously charged with sulphur. It may also be effected by immersing very thin sheets of caoutchouc in a solution of 1 part of chloride of sulphur in 60 parts of bisulphide of carbon; then simple exposure to the air causes it to take the character of vulcanized caoutchouc without the aid of heat. Thus treated, caoutchouc remains elastic at all moderate temperatures; in its ordinary state it is quite rigid at a temperature of 4.4°C . (40°F .); it is not affected by heat short of the vulcanizing

point, and acquires extraordinary powers of resisting compression. It does not readily undergo solution in naphtha or turpentine; the sulphur gradually destroys its elasticity, rendering it brittle and subject to decay.

VULCANITE.—If the vulcanized rubber be exposed to a still higher temperature, 148.5° to 176.6° C. (300° to 350° F.), it assumes a carbonized appearance, becomes black, hard, and like horn, and is termed *vulcanite* or *ebonite*, and may be used for most purposes to which horn is adapted. However, it should not come into contact with silver or gold utensils, as the action of the sulphur tarnishes them. Vulcanite becomes negatively electric by friction, is one of the best insulators of electricity known, and appears to resist the action of nearly all solvents. A much higher percentage of sulphur (from 30 to 35 per cent) also enters into the preparation of this hard variety of vulcanized India rubber. For details regarding the manufacture of hard-rubber articles, and the treatment of India rubber in general, we refer the reader to Prof. S. P. Sadtler's most instructive *Handbook of Industrial Organic Chemistry*, 1895.

Action, and Medical and Surgical Uses.—Caoutchouc is employed for a number of purposes, as rubbing out the writing made by lead-pencils; as a cement or lute by chemists and others, being first fused; for forming tubes of various kinds for surgical and other purposes; and it also enters largely into the preparation of waterproof cloth. Innumerable surgical appliances and instruments are made of soft and hard rubber. It is preferred to metal in many instances where a non-corrosive material is desired, and its durability, lightness, firmness and cheapness are in favor of its selection. Tubes—drainage, stomach, and rectal—syringes, specula, catheters, bougies, pessaries, nipple-shields, dilators, truss-pads, artificial nose, ears, and other parts, orthopaedic and other surgical appliances are constructed from it. Rubber sheets, bed-pans, and when woven into fabrics, rubber cloth, and stockings, bandages, and other appliances for even compression, hot-water bags, etc., are among the many useful articles of which it forms the whole or a part. Indeed, its peculiar character has rendered it useful in various and numerous ways in the arts, sciences, and for domestic purposes. Softened by heat, it has been applied over small bleeding orifices to check further hemorrhage; also to arrest toothache, by placing some of it in the abnormal cavity so as to protect the dental nerve from atmospheric action. Externally, it has been used as an ingredient of adhesive plasters and liniments. Caoutchouc dissolved in oil of origanum or cajuput, and spread upon oil-silk or cloth, and allowed to dry, forms an excellent stimulating plaster for many local difficulties. Skin diseases, as *eczema*, *psoriasis*, etc., and *burns* and ill-conditioned *ulcers* have been treated by wearing next to the skin thin sheets of rubber or rubber cloth, which prevents the escape of the perspiration, thus rendering the parts moist and soft. Its use in these conditions is not commendable. *Swelled testicles* have been strapped and compressed by thin bands of caoutchouc, and for even compression and support the rubber stocking and other woven-rubber fabrics are extensively used in *varicosities*, *hydrocele*, *varicocele*, *ventral hernia*, *pendulous abdomen*, *prolapse of the rectum* and other similar conditions. A grain or 2 of caoutchouc has been administered in *consumption*, repeating it 3 times a day, but its results have not been such as to bring it into general use. It is seldom or never employed internally, and certainly has nothing to recommend it in a medical sense.

Related Preparations.—**MARINE GLUE, or CEMENT**, is made by digesting from 2 to 4 parts of caoutchouc, cut into small pieces, in 34 parts of coal-tar naphtha, promoting solution by the application of heat, and by agitation. When the solution has the consistence of thick cream, add 62 or 64 parts of powdered shellac, and heat the mixture slowly, constantly stirring it, until complete fusion and combination have been effected. Pour the mixture while still hot on plates of metal, so that it may cool in thin sheets like leather. In using the cement put some of it into an iron vessel, and heat it to about 120° C. (248° F.), and apply it with a brush to the surfaces to be joined.

MINERAL CAOUTCHOUC.—An undetermined substance, differing from petroleum products, and found in deposits a foot or less in depth in Australia, has been named *mineral caoutchouc*, from its marked resemblance to caoutchouc. Whether it is of animal or mineral origin is at present undetermined.

ARTIFICIAL CAOUTCHOUC is an elastic body produced by acting upon a solution of glue with sodium tungstate and hydrochloric acid. The precipitate formed upon the addition of the latter is highly elastic at 29.5° to 40.5° C. (85° to 105° F.), and becomes solid and brittle upon cooling. The process was discovered, in 1871, by Prof. Sounenschein (*Amer. Jour. Pharm.*, 1871, p. 471).

ELATERINUM (U. S. P.)—ELATERIN.

FORMULA: $C_{25}H_{40}O_4$. **MOLECULAR WEIGHT:** 347.20.

"A neutral principle obtained from elaterium, a substance deposited by the juice of the fruit of *Ecballium Elaterium* (Linné), A. Richard (*Nat. Ord.*—Cucurbitaceæ)"—(*U. S. P.*).

Preparation.—*Elaterinum* is the principle on which the active properties of elaterium depend. It was first obtained by Morries. Hennel procured it by separating the green resin (chlorophyll) from the crystalline matter of the alcoholic extract of elaterium (see *Elaterium*), by ether, which took up the resin and left the elaterin. The latter was then purified by solution in hot alcohol and subsequent crystallization.

According to Flückiger (*Pharmacographia*), the best method of obtaining elaterin is to exhaust elaterium by means of chloroform; treat the solution so obtained with ether, upon which white crystals of elaterin at once separate. Wash with a small quantity of ether, and recrystallize the pure elaterin from chloroform. This process has been adopted by the *British Pharmacopæia*. Good elaterium should yield from 20 to 25 per cent of elaterin. Less is obtained as the fruit approaches maturity. As high as 50 per cent has been isolated (Walz).

Description and Tests.—Pure elaterin, as officially described, occurs in "minute, white, hexagonal scales, or prismatic crystals, without odor, and having a slightly acrid, bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 4250 parts of water, and in 337 parts of alcohol; in 1820 parts of boiling water, and in 34 parts of boiling alcohol; also soluble in 543 parts of ether, or in 2.4 parts of chloroform. At 190° C. (374° F.) the crystals begin to agglutinate, and at about 209° C. (408.2° F.) they melt, forming a yellowish-brown liquid. When ignited, they are consumed without leaving a residue. Elaterin is neutral to litmus paper. Elaterin is dissolved by solutions of the alkalis, and reprecipitated on supersaturating with an acid. When dissolved in cold, concentrated sulphuric acid, it causes the latter to become yellow at first, which color gradually changes to scarlet. On dissolving some crystals of elaterin in melted carbolic acid, and then adding a few drops of strong sulphuric acid, a crimson color will be developed, which soon becomes scarlet. An alcoholic solution of elaterin should not be precipitated by tannic acid T.S., mercuric chloride T.S., or platinic chloride T.S. (absence of, and difference from, alkaloids)"—(*U. S. P.*). Elaterin is possessed of all the activity of elaterium, being considerably stronger and always more definite in strength and quality. Its alcoholic solution is the most active preparation.

Action, Medical Uses, and Dosage.—(See *Elaterium*.) The dose of elaterin is from $\frac{1}{16}$ to $\frac{1}{8}$ grain, the latter being a rather large dose. Not more than $\frac{1}{16}$ to $\frac{1}{8}$ grain should be administered as a beginning dose.

ELATERIUM.—ELATERIUM.

The feculence of the juice of the fruit of *Ecballium Elaterium* (Linné), A. Richard. (*Ecballium officinale*, Nees; *Ecballium agreste*, Reichenbach; *Momordica Elaterium*, Linné; *Elaterium cordifolium*, Moench).

Nat. Ord.—Cucurbitaceæ.

COMMON NAMES AND SYNONYMS (of plant producing it): *Squirting cucumber*, *Wild cucumber*, *Wild balsam-apple*, *Cucumis agrestis*, *Cucumis asinus*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 115.

Botanical Source.—The wild, or squirting cucumber, sometimes called wild balsam-apple, is a hispid, scabrous, and glaucous plant. The stems number several from the same root, and are cylindrical, prostrate, and without tendrils. The leaves are cordate, somewhat lobed, crenate-toothed, very rugose, supported on long stalks. The flowers are monœcious and yellow. Male flowers: corolla 5-parted; calyx 5-cleft, with a short tube; stamens triadelphous, with yellow, connate anthers. Female flowers: filaments 3, sterile; style trifid; ovary 3-celled. The fruit is oblong, obtuse at each end, hispid, disarticulating from its stalk with

violence, expelling its seeds and mucus with considerable force, in consequence of the sudden contraction of the sides. The seeds are black, compressed, and reticulated (L.).

History and Preparation.—The wild cucumber produces the *Ecbalii Fructus* of the *British Pharmacopœia*. It is indigenous to the south of Europe, growing on poor soils, in waste places, and flowering in July. It has been extensively cultivated in England for medicinal purposes, where, however, it dies in the winter. It could be cultivated in our country, as it thrives well, requiring but little attention. The medicinal part is obtained by sedimentation from the juice of the pulp, and forms the *Elaterium* of commerce. The process of the *British Pharmacopœia* for preparing it is essentially as follows: Slice nearly ripe wild cucumbers, express the juice gently, and pass it through a fine hair sieve; then set it aside for some hours until the thicker part has subsided. Reject the thinner, supernatant liquid, transfer the greenish sediment to a linen strainer, allow it to drain, and then, by means of a gentle heat, dry it on a porous brick. *Elaterium* exists in the juice of the fruit in a soluble condition, but rapidly becomes insoluble when the juice is exposed to the air. *Elaterium* is seldom adulterated, its variation in strength being due both to the difference in the time of its collection, and to faulty modes of preparation. Sometimes it is obtained by subjecting the pulp to too strong pressure, and in other instances, perhaps, by evaporating the juice to an extract. It is then called *Elaterium nigrum*, as against *Elaterium album*, which is made by the method herein described.

Description.—Good *elaterium* is in light, brittle, flat flakes, about $\frac{1}{2}$ line or 1 line in thickness, of a pale-gray color, with a slight greenish or yellowish tinge, having a feeble animal odor (slightly tea-like—*Pharmacographia*), and an intensely bitter, somewhat acrid taste. It frequently carries the marks of the muslin or paper containing it during its desiccation. It floats upon water, forms a green tincture with alcohol, and does not effervesce in diluted hydrochloric acid. Rectified spirit dissolves about half its weight, and such a solution concentrated and added to a warm caustic potash solution should yield a deposit of at least 20 per cent of colorless, crystalline *elaterin* (*Brit. Pharm.*). *Elaterium* of inferior quality is more or less curled, much darker colored, less brittle, and has a glistening fracture. It yields about 6 per cent of *elaterin*, while good *elaterium* yields from 15 to 25 per cent. When obtained from the fruit collected in summer, *elaterium* may contain from 40 to 50 per cent *elaterin*. The *Maltese elaterium* is in larger flakes than the best English, is paler, with hardly a trace of green, is soft and friable, or chalky to the touch, and frequently contains starch, chalk, and other impurities. It is inodorous, heavier than water, and effervesces with diluted hydrochloric acid.

Chemical Composition.—Mr. Hennel obtained from *elaterium* 44 parts of *elaterin*, 17 parts of green resin, 6 of starch, 7 of saline matters, and 26 of woody fiber (P.). Pectin, gummy substances, and albumen have also been found in it. Its watery solution should be wholly or nearly free from starch, as shown by its behavior to iodine solution. Its most important constituent is the drastic principle *elaterin* ($C_{20}H_{32}O_8$) (see *Elaterinum*). From the whole plant, including the root, four principles, said to be found also in *elaterium*, were detected by Walz in 1859. They are the yellow, crystallizable glucosid, *prophetin* (found also in the fruit of *Cucumis prophetarum*, Linné); *ecballin* (*ecballic acid*), a bitter, acrid, amorphous, resin-like body; amorphous, non-bitter *hydro-elaterin*; and an extremely bitter, amorphous body, *elaterid*. For a more detailed account of these substances see Husemann and Hilger, *Pflanzenstoffe*, p. 1353.

Action, Medical Uses, and Dosage.—*Elaterium* is an energetic hydragogue cathartic, operating with great violence in doses of a few grains, causing diffuse inflammation of the stomach and bowels, characterized by vomiting, griping pain, and profuse diarrhœa. It is the most powerful of our hydragogue purgatives, and for this purpose should be used only in plethoric states. In ordinary medicinal doses it produces copious watery evacuations, attended with considerable depression of the circulation and nervous system, and most generally nausea and vomiting. Hence, it is often used in *dropsy*, especially *pulmonary edema* and *ascites*, to aid in removing the effused fluid, as a revulsive in *cerebral affections*, and wherever a hydragogue or revellent effect is indicated. It has been used in this

manner in *narcotic poisoning*. It causes an enormous flow of watery serum from the blood and mucous structures, and it has been aptly said that one may be "bled through the tissues" with a full dose of elaterium. It also augments the urinary discharge. The dose of the common commercial article, as a cathartic, is from $\frac{1}{2}$ to $\frac{1}{4}$ grain, administered every 1 or 2 hours until it operates; of Clutterbuck's elaterium, considered the best, and so named because it is prepared after the process recommended by Clutterbuck, from $\frac{1}{2}$ to $\frac{1}{16}$ of a grain every 3 or 4 hours; of *elaterin*, from $\frac{1}{16}$ to $\frac{1}{8}$ of a grain, best given in form of tincture. A few grains of capsicum added to each dose of elaterium will prevent its nauseating effects. Morris recommends a tincture of elaterin made by dissolving 1 grain in 1 fluid ounce of alcohol, to which 4 drops of nitric acid have been added; the dose is from 20 to 40 drops diluted with cinnamon water. Great care should be exercised in administering elaterium to the debilitated, or to old and infirm individuals, and it is always contraindicated by gastro-intestinal inflammation. Prof. Locke recommends the following: In *dropsy with liver complications*, R Elaterium, gr. j; podophyllin, grs. ij; powd. ext. colocynth comp., grs. xvj; ext. hyoscyamus, q. s. to make a pill mass. Mix. Divide into 8 pills. Give 1 pill every 3 hours until the bowels are freely moved. In *dropsy with heart complications*, R Elaterium, gr. j; powd. digitalis, 3ss; powd. squill, 3ss; ext. hyoscyamus, q. s. to make a pill mass. Mix. Divide into 20 pills. Give 1 or 2 pills every 3 hours until the bowels move freely; after that 1 or 2 pills each day. For *uræmic convulsions with ascites*, particularly that following *scarlatina*, R Elaterium, gr. j; powd. ext. colocynth comp., grs. xv. Mix. Divide into 8 pills. Administer 1 pill every hour until free evacuations are produced (*Syllabus of Ec. Mat. Med.*). In the latter condition, gelsemium, jaborandi, or apocynum may be associated with the elaterium treatment if indicated. "For the first time, I now introduce this article to the profession as a specific in *chronic inflammation of the neck of the bladder*, in which disease I have successfully used it for many years. I am not aware of its ever having been named heretofore for this purpose. It is more especially useful in cases in which there is a constant, more or less painful sensation in the region of the neck of the bladder, where the urine passes in a torrent as if poured through the urethra, and where, after micturition, there is a violent, cramp-like aching in the parts, often extending over the whole lower pelvic region and thighs. The saturated tincture (elaterium gr. j, alcohol fl. 3j), is employed in doses varying from 5 to 30 minims; I usually mix it with simple sarsaparilla or other syrup, so that a teaspoonful of the mixture may be taken at a dose, and be repeated 3 or 4 times a day. It must be used carefully, so that it does not purge, although occasionally cases will be met with in which, if its purgative effect is produced by the first doses, its subsequent influence will be more decided. The dose should be small at first, and be gradually increased, as it can be borne. I have also found some good effects from it in *chronic gastritis* and *chronic inflammation* of other mucous membranes" (John King). It must be remembered that it is the minute dose that allays *gastric irritation*. Sore, tender, and heavy, or dragging sensations in the region of the bladder, or in the whole pelvic or perineal region, and accompanied with tenesmic passage of urine containing an abundance of mucus or muco-pus, are relieved by small doses of elaterium more readily than by any other drug. It should also be remembered that in the administration of elaterium only the smallest dose that will accomplish results should be used, for even small doses are apt to occasion emesis and other unpleasant results that may interfere with a successful treatment.

For *irritable and painful states of the bladder*, the small dose is now preferred: R Specific elaterium gtt. v to x to aqua fl. 3iv. Dose, a teaspoonful every 2 or 3 hours. The ordinary dose of elaterium is from $\frac{1}{16}$ to $\frac{1}{8}$ grain; of elaterin $\frac{1}{16}$ to $\frac{1}{8}$ grain. It must be remembered that both elaterium and elaterin greatly vary in strength.

Specific Indications and Uses.—Chronic cystitis with "constant, more or less painful sensation in the region of the neck of the bladder, where the urine passes in a torrent as if poured through the urethra, and where, after micturition, there is a violent, cramp-like aching in the parts, often extending over the whole lower pelvic region and thighs" (King); deep soreness or tenderness in bladder, pelvis, or perineum, with tenesmic passage of urine loaded with mucus or muco-pus;

constipation. In cathartic doses: Dropsy of plethora; ascites and palmar oedema; cerebral congestion.

Related Species.—*Momordica buchu*. Nat. Ord.—Cucurbitaceae. Brasil. Resquirting cucumber in its properties, though its drastic qualities are said to be harder. *Med. Jour.*, 1887).

ELEMI.—ELEMI.

A concrete oleoresin obtained by incisions, the source of which has not been determined, though thought to be from *Canarium commune*, Linné (N. Burseraceæ).

SYNONYMS: *Resina elemi*, *Gummi elemi*, *Manila elemi*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 61.

Botanical Source and History.—Several resinous bodies have at times been placed in the European market under the name Elemi, and are believed to have been the products of plants of the natural order Burseraceæ. The *British Pharmacopœia* recognizes a product from the Philippine Islands as *Manila elemi*, thought to be derived from the species above named.

Description.—*Manila elemi*, when recent, occurs in transparent, soft, lar masses, consisting of a solution of solid resin in essential oil. External has a light, canary-yellow color, and, as found in commerce, is largely presenting an opaque and granular fracture, due to the crystallization of the resin. Chips and other foreign substances are often found in the solid fragments. Wetted with a little alcohol, elemi readily disintegrates, showing a multitude of small, crystalline needles. It melts easily, a transparent fluid resulting. It has an aromatic, warm, acrid taste, and a fragrant odor, resembling that of binthinate, the drug in many respects closely resembling the latter substances. It is insoluble in water, partly soluble in cold, and completely in hot alcohol; easily soluble also in oil of turpentine and ether.

Chemical Composition.—A neutral volatile oil, strongly dextrogyrate, less, and fragrant, was obtained to the extent of at least 10 per cent by the distillation of *Pharmacographia*. Deville, on the other hand (1841), found oil of elemi laevogyre. Maujean (1821) found in this drug two resinous bodies—one soluble in cold spirit, the other in hot spirit only. The principal constituent of the resin is the part soluble in cold alcohol. It is an amorphous, non-acid resin. Insoluble in this solvent is a crystalline magma, soluble in hot alcohol. Upon cooling, yields 25 per cent (of the original elemi) of a crystalline substance called *amyryn* by Baup (1851). It is also soluble in ether, chloroform, and disulphide. Ciamician, in 1878, distilled it from zinc dust, obtaining *toluene*, *ethyl-benzene*, and *ethyl-naphthalene*. Vesterberg (1887) differentiated among two isomers of the formula $C_{20}H_{30}O$, derived from two isomeric hydrocarbons ($C_{20}H_{30}$) of the melting points $135^{\circ}C$. ($275^{\circ}F$.) and $194^{\circ}C$. ($381.2^{\circ}F$.) (1874), from the mother-liquors of *amyryn*, obtained a small quantity of a substance which he called *elemic acid* ($C_{20}H_{30}O_2$). It forms large crystals, melts at $302^{\circ}F$., is insoluble in water, soluble in alcohol, ether, and amyl alcohol. *Bryoidin* is a crystallizable, neutral substance, observed by Baup in the residual liquid obtained by the distillation of a mixture of water and the essential oil, soluble in hot water and crystallizes upon cooling. Flückiger purified it by distillation in a current of carbonic acid and found its composition to be $(C_{20}H_{30}O)_2$, and its melting point $133.5^{\circ}C$. ($271.5^{\circ}F$.). Dry hydrochloric acid gas causes *bryoidin* to undergo changes of color ranging from red to violet, blue and green. *Amyryn* remains unchanged under similar treatment. A *bitter principle*, observed by Bonastre (1824) was obtained by Flückiger in the mother-liquor of *bryoidin*, in the form of a soft, resinous mass (Flückiger, *Pharmacographia*).

Action, Medical Uses, and Dosage.—This agent closely resembles turpentine, and undoubtedly might be substituted for them. The action of the oil and oil of turpentine are also similar. Elemi is, however, only used in European medicine externally, in plaster and ointment form, as a dressing for indolent sores, etc.

Related Products.—**BRAZILIAN ELEMI.** The product of several species of greenish-yellow, fragrant, translucent resin, sometimes opaque, whitish-gray or yellow.

is composed of small needles. The odorous resin exuding from the trunks of species of *Icica* (e. g., *I. Icicariba*, De Candolle) is consumed as incense in the churches of French Guiana (F. L. Simmonds, *Amer. Jour. Pharm.*, 1895, p. 253).

MEXICAN ELEMI. *Vera Crus elemi*.—The product of *Amyris elemifera* of Royle; also of *Elaphrium Jacquinianum* (*Bursera tomentosa*) and *E. elemifera* (*Amer. Journ. Pharm.*, 1895, p. 253). Occurs in opaque (sometimes translucent) fragments or semi-cylindrical pieces, is pale-yellow or nearly white, and has an agreeable odor. It may be readily masticated. Treatment with cold alcohol reveals white needles, probably of amyrin.

MAURITIUS ELEMI.—The product of *Colophonia Mauritiana*, De Candolle. Mauritius. When fresh this is a liquid, but subsequently hardens, and finally resembles the Manilla product, especially in the abundance of residual amyrin crystals by treatment with cold alcohol.

AFRICAN ELEMI, or ORIENTAL ELEMI. *Lubdn meyeti*, *Lubdn mati*.—Exudes from *Bonwelli Frereana*, Birdwood. Occurs in tears, fragments, or large stalactitic pieces, whose fracture is shell-like, exhibiting a transparent, amber-yellow interior. It is encrusted with a thin, opaque crust. The thin, paper-like, brown bark may be found adhering to the masses. The taste is mildly terebinthinous, while the odor is said to be agreeable, resembling a mixed odor of turpentine and lemon. Alcohol practically dissolves it. It was found to be a mixture of a dextrogyrate terpene ($C_{10}H_{16}$), and a probably levogyre oxygenated oil (*Pharmacographia*).

OIL of MEXICAN LIGNALORS is yielded by the wood of *Bursera delapachiana*. It has the combined fragrance of lemon and jasmine.

ELIXIRIA.—ELIXIRS.

Definition and History.—The term "Elixir" is an heirloom, and comes to us from the alchemist. Among the alchemical vagaries none stand more conspicuous than the *Elixir Vitæ*. The substance designated in alchemy as an *elixir* may be defined clearly, in the language of Boerhaave, as "An artificial body of such virtue and efficacy as that, being applied to any body of any of the three kingdoms, it shall improve its natural inherent virtues, so as to make it the most perfect thing in its kind. Thus, for instance, if applied to the human body, it will become an universal medicine, and make such a change, both in the solid and fluid parts thereof, as shall render it perfectly sound, and even maintain it in that state, until the parts, being slowly worn away and spent, death gently, and without a struggle, takes possession."

Then came Paracelsus (b. 1493 d. 1541) who is generally accredited with instituting a new era in the study. He demonstrated that alchemy, which flourished in his day, and of which he was a zealous student, could be made of value to the physician. He originated the famous concoction "*Elixir Proprietatis*," made of saffron, aloes, and myrrh, claiming that who ever used it would "live as long as Methuselah;" then he died in his 47th year. Following this came the era of proprietary elixirs, all of them nasty and probably all frauds. Among these we may name *Doffey's Elixir*, *Helmont's Elixir*, *Mynsicht's Elixir*, *Vigani's Elixir*, etc. These naturally were imitated and gave lines of elixirs to the early pharmacopœias. They were first introduced under fanciful names, which spoke of their uses, not of their constituents. They were all very disagreeable and usually bitter, being, in fact, compound tinctures. Finally, the original name became secondary and thus this class of compound tinctures, favorites in medicine until recently, were established. The following list will give the original (elixir) name of a few of these compounds and the resultant compound tincture, as it is still found in our pharmacopœias:

Elixir Salutis gave us Compound Tincture of Senna.

Elixir Paregoricum gave us Camphorated Tincture of Opium.

Elixir Proprietatis gave us Compound Tincture of Aloes.

Elixir Stomachicum gave us Compound Tincture of Gentian.

Elixir Sacrum gave us Tincture of Rhubarb and Aloes.

Gradually the physician and pharmacist, under the march of civilization, revolted against these villainous concoctions. No aim had been made toward making them palatable; indeed, the contrary seemed evident. The *London New Dispensatory* (1770), however, named one elixir containing sugar. But at present, in European pharmacy and medicine, an elixir is still an alcoholic liquid free from sugar.

In 1859, Mr. Alfred B. Taylor, of Philadelphia, published in the *American Journal of Pharmacy* a formula for a sweetened "*Elixir of Calisaya*." The *Druggists'*

Circular of the same year states that no previous formula had been published. Immediately manufacturers of pharmaceutical preparations threw lines of sweetened elixirs on the market. These were really cordials. In 1870 to 1874, the elixir mania was at its height. In 1871, Prof. J. Faris Moore, M. D., representing the American Pharmaceutical Association, on "*Unofficial Preparations*," included formulæ for several of these popular mixtures. In 1872, Prof. C. Lewis Diehl read a paper on the elixir subject before the Louisville College of Pharmacy, which was published generally. The agitation was continued in the American Pharmaceutical Association, but finally the elixir craze died out, not, however, until a few of its members received recognition in the *U. S. P.* The American Elixir is a cordial, made of sugar, spirit, flavors, and drugs. It is not as disagreeable as the European Elixir and in that regard may be entitled to preference. Eclectic physicians have always opposed elixirs. In the following pages will be found formulæ from the *National Formulary*, for those most important. For more extensive lists the reader is referred to the *National Formulary*, and *Elixirs*, by J. U. Lloyd.

National Formulary Elixirs.—**ELIXIR AMMONII BROMIDI** (N. F.), *Elixir of ammonium bromide*.—*Formulary number*, 32: "Ammonium bromide, eighty-five grammes (85 Gm.) [3 oz. av.]; citric acid, four grammes (4 Gm.) [62 grs.]; aromatic elixir (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 Ml]. Dissolve the ammonium bromide and the citric acid in about five hundred cubic centimeters (500 Cc.) [16 fl̄, 435 Ml] of aromatic elixir, by agitation. Then add enough aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 Ml], and filter, if necessary. Each fluid drachm contains 5 grains of ammonium bromide"—(*Nat. Form.*).

ELIXIR AMMONII VALERIANATIS (N. F.), *Elixir of ammonium valerianate*.—*Formulary number*, 33: "Ammonium valerianate, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; chloroform, eight-tenths of a cubic centimeter (0.8 Cc.) [13 Ml]; tincture of vanilla (*U. S. P.*), sixteen cubic centimeters (16 Cc.) [260 Ml]; compound tincture of cudbear (F. 419), sixteen cubic centimeters (16 Cc.) [260 Ml]; water of ammonia (*U. S. P.*), aromatic elixir (*U. S. P.*), of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 Ml]. Dissolve the ammonium valerianate in about seventy-five cubic centimeters (75 Cc.) [2 fl̄, 257 Ml] of aromatic elixir, in a graduated vessel, and add enough water of ammonia, in drops, until a faint excess of it is perceptible in the liquid. Then add the chloroform, tincture of vanilla and compound tincture of cudbear, and finally, enough aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 Ml]. Filter, if necessary. Each fluid drachm contains 2 grains of ammonium valerianate. *Note*.—Should the odor of valerianic acid become perceptible after the elixir has been kept for some time, it may be overcome by slightly supersaturating with water of ammonia"—(*Nat. Form.*).

ELIXIR APII GRAVEOLENTIS COMPOSITUM (N. F.), *Compound elixir of celery*.—*Formulary number*, 36: "Fluid extract of celery seed (F. 139), sixty-two cubic centimeters (62 Cc.) [2 fl̄, 46 Ml]; fluid extract of erythroxylon (*U. S. P.*), sixty-two cubic centimeters (62 Cc.) [2 fl̄, 46 Ml]; fluid extract of kola (F. 175), sixty-two cubic centimeters (62 Cc.) [2 fl̄, 46 Ml]; fluid extract of viburnum prunifolium (*U. S. P.*), sixty-two cubic centimeters (62 Cc.) [2 fl̄, 46 Ml]; alcohol, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl̄, 109 Ml]; aromatic elixir (*U. S. P.*), a sufficient quantity, to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 Ml]. Mix the alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 Ml] of aromatic elixir. To this add the fluid extract of celery seed in several portions, shaking after each addition, and afterwards the other fluid extracts. Finally add enough aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 Ml], allow the mixture to stand 24 hours, and filter. *Note*.—If this preparation is prescribed or quoted under its Latin title, it is recommended that the full title be given, so that the word 'Apii' may not be mistaken for 'Opii'"—(*Nat. Form.*).

ELIXIR BISMUTHI (N. F.), *Elixir of bismuth*.—*Formulary number*, 37: "Bismuth and ammonium citrate, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; water, hot, sixty cubic centimeters (60 Cc.) [2 fl̄, 14 Ml]; water of ammonia (*U. S. P.*), and aromatic elixir (*U. S. P.*), of each a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 Ml]. Dissolve the bismuth and ammonium citrate in the hot water, allow the solution to stand until any undissolved matter has subsided; then decant the clear liquid, and add to the residue just enough water of ammonia to dissolve it. Then mix it with the decanted portion and add enough aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 Ml]. Filter, if necessary. Each fluid drachm represents 2 grains of bismuth and ammonium citrate"—(*Nat. Form.*).

ELIXIR BUCHU (N. F.), *Elixir of buchu*.—*Formulary number*, 38: "Fluid extract of buchu (*U. S. P.*), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl̄, 109 Ml]; alcohol, sixty-two cubic centimeters (62 Cc.) [2 fl̄, 46 Ml]; syrup (*U. S. P.*), sixty-two cubic centimeters (62 Cc.) [2 fl̄, 46 Ml]; magnesium carbonate, fifteen grammes (15 Gm.) [231 grs.]; aromatic elixir (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 Ml]. Mix the fluid extract of buchu with the alcohol, then add seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 Ml], of aromatic elixir, and the syrup. Incorporate with it the magnesium carbonate, and filter. Finally, pass enough aromatic elixir through

the filter to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Each fluid drachm represents about 7½ grains of buchu"—(*Nat. Form.*).

ELIXIR BUCHU COMPOSITUM (N. F.), *Compound elixir of buchu*.—*Formulary number*, 39: "Compound fluid extract of buchu (F. 144), two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 M̄]; alcohol, sixty-two cubic centimeters (62 Cc.) [2 fl̄, 46 M̄]; syrup (U. S. P.), sixty-two cubic centimeters (62 Cc.) [2 fl̄, 46 M̄]; magnesium carbonate, fifteen grammes (15 Gm.) [231 grs.]; aromatic elixir (U. S. P.), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Mix the compound fluid extract of buchu with the alcohol, then add five hundred cubic centimeters (500 Cc.) [16 fl̄, 435 M̄] of aromatic elixir, and the syrup. Incorporate with it the magnesium carbonate, and filter. Finally, pass enough aromatic elixir through the filter to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Each fluid drachm represents 15 minims of compound fluid extract of buchu"—(*Nat. Form.*).

ELIXIR BUCHU ET POTASSII ACETATIS (N. F.), *Elixir of buchu and potassium acetate*.—*Formulary number*, 40: "Potassium acetate, eighty-five grammes (85 Gm.) [3 ozs. av.]; elixir of buchu (F. 38), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Dissolve the potassium acetate in about seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 M̄] of elixir of buchu; filter, if necessary, and add enough elixir of buchu to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Each fluid drachm represents 5 grains of potassium acetate and about 7 grains of buchu"—(*Nat. Form.*).

ELIXIR CAFFEINÆ (N. F.), *Elixir of caffeine*.—*Formulary number*, 41: "Caffeine, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; diluted hydrobromic acid (U. S. P.), four cubic centimeters (4 Cc.) [65 M̄]; syrup of coffee (F. 367), two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 M̄]; aromatic elixir (U. S. P.), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Rub the caffeine, in a mortar, with the diluted hydrobromic acid, and about one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl̄, 109 M̄] of aromatic elixir, until solution is effected. Then add the syrup of coffee, and lastly, enough aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Filter, if necessary. Each fluid drachm contains 1 grain of caffeine"—(*Nat. Form.*).

ELIXIR CALCII HYPOPHOSPHITIS (N. F.), *Elixir of calcium hypophosphite*.—*Formulary number*, 43: "Calcium hypophosphite, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; citric acid, four grammes (4 Gm.) [62 grs.]; aromatic elixir (U. S. P.), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Dissolve the calcium hypophosphite in nine hundred cubic centimeters (900 Cc.) [30 fl̄, 308 M̄] of aromatic elixir, and filter. Dissolve the citric acid in the filtrate, and pass enough aromatic elixir through the filter to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Each fluid drachm contains 2 grains of calcium hypophosphite"—(*Nat. Form.*).

ELIXIR CALCII LACTOPHOSPHATIS (N. F.), *Elixir of calcium lactophosphate*.—*Formulary number*, 44: "Calcium lactate, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; phosphoric acid (U. S. P., 85 per cent), eight cubic centimeters (8 Cc.) [130 M̄]; water, sixty cubic centimeters (60 Cc.) [2 fl̄, 14 M̄]; syrup (U. S. P.), sixty cubic centimeters (60 Cc.) [2 fl̄, 14 M̄]; aromatic elixir (U. S. P.), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Triturate the calcium lactate with the phosphoric acid, the water, and the syrup, until the salt is dissolved. Then add enough aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄], and filter. Each fluid drachm represents 1 grain of calcium lactate, or about 1½ grains of so-called calcium lactophosphate"—(*Nat. Form.*).

ELIXIR CATHARTICUM COMPOSITUM (N. F.), *Compound cathartic elixir*.—*Formulary number*, 45: "Fluid extract of senna (U. S. P.), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl̄, 109 M̄]; fluid extract of podophyllum (U. S. P.), sixty-two cubic centimeters (62 Cc.) [2 fl̄, 46 M̄]; fluid extract of leptandra (U. S. P.), fifty cubic centimeters (50 Cc.) [1 fl̄, 332 M̄]; fluid extract of jalap (F. 162), fifty cubic centimeters (50 Cc.) [1 fl̄, 332 M̄]; potassium and sodium tartrate, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; sodium bicarbonate, sixteen grammes (16 Gm.) [247 grs.]; compound elixir of taraxacum (F. 111), two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 M̄]; elixir of glycyrrhiza (F. 76), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Mix the fluid extracts with the compound elixir of taraxacum; in the mixture dissolve the salts by agitation, and add enough elixir of glycyrrhiza to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. The product should not be filtered, and should be shaken up whenever any of it is dispensed. The average dose for an adult is 2 fluid drachms"—(*Nat. Form.*).

ELIXIR CHLOROFORMI COMPOSITUM (N. F.), *Compound elixir of chloroform*.—*Formulary number*, 46: "Chloroform, one hundred and ninety cubic centimeters (190 Cc.) [6 fl̄, 204 M̄]; tincture of opium (U. S. P.), one hundred and ninety cubic centimeters (190 Cc.) [6 fl̄, 204 M̄]; spirit of camphor (U. S. P.), one hundred and ninety cubic centimeters (190 Cc.) [6 fl̄, 204 M̄]; aromatic spirit of ammonia (U. S. P.), one hundred and ninety cubic centimeters (190 Cc.) [6 fl̄, 204 M̄]; alcohol, two hundred and thirty-five cubic centimeters (235 Cc.) [7 fl̄, 464 M̄]; oil of cinnamon (cassia), five cubic centimeters (5 Cc.) [81 M̄]. Mix the chloroform with the alcohol, then add the oil of cinnamon, aromatic spirit of ammonia, spirit of camphor, and tincture of opium. Allow the mixture to stand a few hours, and filter in a well-covered funnel. Each fluid drachm represents about 1 grain of opium and 11 minims of chloroform. *Note*.—This preparation is called chloroform paregoric in some sections of the country. It is recommended that this title be abandoned, to prevent confusion with the official paregoric or *Tinctura Opii Camphorata*—(*Nat. Form.*).

ELIXIR CINCHONÆ (N. F.), *Elixir of cinchona*, *Elixir of calisaya*.—*Formulary number*, 47: "Tincture of cinchona (U. S. P.), one hundred and fifty cubic centimeters (150 Cc.) [5 fl̄, 35 M̄]; syrup (U. S. P.), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl̄, 109 M̄]; glycerin,

one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl. 3, 109 M.]; aromatic elixir (U.S.P.), six hundred cubic centimeters (600 Cc.) [20 fl. 3, 138 M.]. Mix the liquids, allow to stand as long as convenient, and filter through a wetted filter. Each fluid ounce represents about 14 grains of yellow cinchona"—(Nat. Form.).

ELIXIR CINCHONÆ DETANNATUM (N. F.), *Detannated elixir of cinchona, Detannated elixir of calisaya*.—Formulary number, 48: "Detannated tincture of cinchona (F. 403), one hundred and fifty cubic centimeters (150 Cc.) [5 fl. 3, 35 M.]; syrup (U.S.P.), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl. 3, 109 M.]; glycerin, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl. 3, 109 M.]; aromatic elixir (U.S.P.), six hundred cubic centimeters (600 Cc.) [20 fl. 3, 138 M.]. Mix the liquids, and filter, if necessary. Each fluid ounce represents about fourteen grains (14 grains) of yellow cinchona. *Note*.—This preparation may be used when elixir cinchonæ is directed in combination with preparations of iron, but may be replaced by compound elixir of quinine (F. 96), colored by the addition of fifteen cubic centimeters (15 Cc.) [2 fl. 3, 14 M.] of compound tincture of cudbear (F. 419), to one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M.]"—(Nat. Form.).

ELIXIR CINCHONÆ ET FERRI (N. F.), *Elixir of cinchona and iron, Elixir of calisaya and iron, Ferrated elixir of calisaya*.—Formulary number, 50: "Phosphate of iron (U.S.P.), thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; water, boiling, sixty cubic centimeters (60 Cc.) [2 fl. 3, 14 M.]; compound elixir of quinine (F. 96), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M.]. Dissolve the phosphate of iron in the boiling water, then add enough compound elixir of quinine to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M.], and filter. Each fluid drachm contains 2 grains of phosphate of iron"—(Nat. Form.).

ELIXIR CINCHONÆ, FERRI ET STRYCHNINÆ (N. F.), *Elixir of cinchona, iron and strychnine, Elixir of calisaya, iron and strychnine*.—Formulary number, 55: "Strychnine sulphate, one hundred and seventy-five milligrammes (0.175 Gm.) [2.7 grs.]; water, fifteen cubic centimeters (15 Cc.) [2 fl. 3, 14 M.]; elixir of cinchona and iron (F. 50), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M.]. Dissolve the strychnine sulphate in the water and add enough elixir of cinchona and iron to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M.]. Each fluid drachm contains $\frac{1}{15}$ grain of strychnine sulphate, and about 2 grains of phosphate of iron"—(Nat. Form.).

ELIXIR CURASSAO (N. F.), *Elixir of curaçao, Curaçao cordial*.—Formulary number, 58: "Spirit of curaçao (F. 348), sixteen cubic centimeters (16 Cc.) [2 fl. 3, 14 M.]; orris root, in fine powder, four grammes (4 Gm.) [62 grs.]; deodorized alcohol, two hundred and fifty cubic centimeters (250 Cc.) [8 fl. 3, 218 M.]; citric acid, seven grammes (7 Gm.) [108 grs.]; syrup (U.S.P.), five hundred cubic centimeters (500 Cc.) [16 fl. 3, 435 M.]; magnesium carbonate, fifteen grammes (15 Gm.) [231 grains]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M.]. Mix the spirit of curaçao with the alcohol, add the orris root, the magnesium carbonate, and one hundred and eighty-five cubic centimeters (185 Cc.) [6 fl. 3, 123 M.] of water. Allow the mixture to stand 12 hours, occasionally agitating; then pour it on a wetted filter, returning the first portions of the filtrate until it runs through clear, and pass enough water through the filter to make the filtrate measure five hundred cubic centimeters (500 Cc.) [16 fl. 3, 435 M.]. In this dissolve the citric acid, and finally add the syrup"—(Nat. Form.).

ELIXIR ERYTHROXYLI (N. F.), *Elixir of erythroxylon, Elixir of coca*.—Formulary number, 61: "Fluid extract of erythroxylon (U.S.P.), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl. 3, 109 M.]; alcohol, sixty-two and one-half cubic centimeters (62.5 Cc.) [2 fl. 3, 54 M.]; syrup (U.S.P.), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl. 3, 109 M.]; tincture of vanilla (U.S.P.), sixteen cubic centimeters (16 Cc.) [2 fl. 3, 14 M.]; purified talcum (F. 395), fifteen grammes (15 Gm.) [231 grs.]; aromatic elixir (U.S.P.), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M.]. Mix the fluid extract with the alcohol, the syrup, and six hundred and fifty cubic centimeters (650 Cc.) [21 fl. 3, 470 M.] of aromatic elixir, add the purified talcum and incorporate the latter thoroughly. Let the mixture stand during 48 hours, if convenient, shaking occasionally; then filter, add the tincture of vanilla to the filtrate, and pass enough aromatic elixir through the filter to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M.]. Each fluid drachm represents $7\frac{1}{2}$ grains of erythroxylon (coca)"—(Nat. Form.).

ELIXIR FERRI HYPOPHOSPHITIS (N. F.), *Elixir of hypophosphate of iron*.—Formulary number, 65: "Solution of hypophosphate of iron (F. 219), one hundred cubic centimeters (100 Cc.) [3 fl. 3, 183 M.]; aromatic elixir (U.S.P.), nine hundred cubic centimeters (900 Cc.) [30 fl. 3, 208 M.]. Mix, allow the mixture to stand a few days in a cool place, and filter, if necessary. Each fluid drachm contains 1 grain of hypophosphate of iron (ferric)"—(Nat. Form.).

ELIXIR FERRI PHOSPHATIS (N. F.), *Elixir of phosphate of iron*.—Formulary number, 67: "Phosphate of iron (U.S.P.), thirty-five grammes (35 Gm.) [1 oz. av., 103 M.]; water, sixty cubic centimeters (60 Cc.) [2 fl. 3, 14 M.]; aromatic elixir (U.S.P.), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M.]. Dissolve the phosphate of iron in the water with the aid of heat; then mix this solution with a sufficient quantity of aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M.]. Filter, if necessary. Each fluid drachm contains 2 grains of phosphate of iron"—(Nat. Form.).

ELIXIR FERRI PHOSPHATIS, QUININÆ ET STRYCHNINÆ (N. F.), *Elixir of phosphate of iron, quinine and strychnine*.—Formulary number, 69: "Phosphate of iron (U.S.P.), seventeen and one-half grammes (17.5 Gm.) [270 grs.]; quinine (alkaloid), eight and three-fourths grammes (8.75 Gm.) [135 grs.]; strychnine (alkaloid), two hundred and seventy-five milligrammes (0.275 Gm.) [4.24 grs.]; alcohol, one hundred and thirty cubic centimeters (130 Cc.) [4 fl. 3, 180 M.]; water, fifty cubic centimeters (50 Cc.) [1 fl. 3, 332 M.]; aromatic elixir (U.S.P.), a suffi-

cient quantity to make one thousand cubic centimeters (1000 Cc.) [83 fl̄, 391 M̄]. Dissolve the alkaloids in the alcohol and add seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 M̄] of aromatic elixir, then dissolve the phosphate of iron in the water, using heat, if necessary, and add to the previous mixture. Finally, add enough aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Each fluid drachm contains 1 grain of phosphate of iron, $\frac{1}{2}$ grain of quinine, and $\frac{1}{17}$ grain of strychnine. *Note*.—When this elixir is mixed with water, it may become cloudy or opaque through the separation of some of its constituents"—(*Nat. Form.*).

ELIXIR FERRI PYROPHOSPHATIS (N. F.), *Elixir of pyrophosphate of iron*.—*Formulary number*, 70: "Pyrophosphate of iron (U. S. P.), thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; water, sixty cubic centimeters (60 Cc.) [2 fl̄, 14 M̄]; aromatic elixir (U. S. P.), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Dissolve the pyrophosphate of iron in the water, and add enough aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Filter, if necessary. Each fluid drachm contains 2 grains of pyrophosphate of iron"—(*Nat. Form.*).

ELIXIR FERRI, QUININÆ ET STRYCHNINÆ (N. F.), *Elixir of iron, quinine and strychnine*.—*Formulary number*, 71: "Tincture of citro-chloride of iron (F. 407), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl̄, 109 M̄]; quinine hydrochlorate, eight and one-half grammes (8.5 Gm.) [131 grs.]; strychnine sulphate, one hundred and seventy-five milligrammes (0.175 Gm.) [2.7 grs.]; alcohol, thirty cubic centimeters (30 Cc.) [1 fl̄, 7 M̄]; aromatic elixir (U. S. P.), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Dissolve the alkaloidal salts in about seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 M̄] of aromatic elixir, then add the tincture and the alcohol, and finally, enough aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Filter, if necessary. Each fluid drachm represents about 1 grain of ferric chloride, $\frac{1}{2}$ grain of quinine hydrochlorate, and $\frac{1}{17}$ grain of strychnine sulphate"—(*Nat. Form.*).

ELIXIR FRANGULÆ (N. F.), *Elixir of frangula, Elixir of buckthorn*.—*Formulary number*, 72: "Fluid extract of frangula (U. S. P.), two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 M̄]; alcohol, sixty cubic centimeters (60 Cc.) [2 fl̄, 14 M̄]; compound elixir of taraxacum (F. 111), two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 M̄]; aromatic elixir (U. S. P.), four hundred and forty cubic centimeters (440 Cc.) [14 fl̄, 422 M̄]. Mix them, allow the mixture to stand during 48 hours, if convenient, and filter. Each fluid drachm represents 16 grains of frangula"—(*Nat. Form.*).

ELIXIR GENTIANÆ (N. F.), *Elixir of gentian*.—*Formulary number*, 73: "Fluid extract of gentian (U. S. P.), thirty-five cubic centimeters (35 Cc.) [1 fl̄, 88 M̄]; compound spirit of cardamom (F. 347), twenty-five cubic centimeters (25 Cc.) [408 M̄]; solution of tersulphate of iron (U. S. P.), twenty-five cubic centimeters (25 Cc.) [408 M̄]; water of ammonia (U. S. P.), twenty-eight cubic centimeters (28 Cc.) [455 M̄]; alcohol, water, aromatic elixir (U. S. P.), of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Dilute the solution of tersulphate of iron with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 M̄] of cold water, and add it, constantly stirring, to the water of ammonia, previously diluted with an equal volume of cold water. Collect the precipitate on a well wetted muslin strainer, allow it to drain completely, return it to the vessel, mix it intimately with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 M̄] of water, and again drain. Repeat this operation once more with the same quantity of water. When the precipitate has been completely drained for the third time, fold the strainer, and press it gently so as to remove the water as completely as possible without loss of magma; then remove the magma into a tared bottle, and ascertain its weight. Now add to the magma one-fifth ($\frac{1}{5}$) of its weight of alcohol, the fluid extract, the compound spirit, and seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 M̄] of aromatic elixir, and shake the mixture occasionally during 24 hours. Filter through paper, and pass enough aromatic elixir through the filter to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Each fluid drachm represents about 2 grains of gentian"—(*Nat. Form.*).

ELIXIR GENTIANÆ CUM TINCTURA FERRI CHLORIDI (N. F.), *Elixir of gentian with tincture of chloride of iron*.—*Formulary number*, 74: "Tincture of citro-chloride of iron (F. 407), one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M̄]; elixir of gentian (F. 73), nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 M̄]. Mix and filter, if necessary. Each fluid drachm represents about $\frac{1}{2}$ grain of ferric chloride, and nearly 2 grains of gentian"—(*Nat. Form.*).

ELIXIR GLYCYRRHIZÆ AROMATICUM (N. F.), *Aromatic elixir of glycyrrhiza, Aromatic elixir of liquorice*. *Formulary number*, 77: "Fluid extract of glycyrrhiza (U. S. P.), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl̄, 109 M̄]; oil of cloves, four-tenths of a cubic centimeter (0.4 Cc.) [6.5 M̄]; oil of cinnamon (Ceylon), four-tenths of a cubic centimeter (0.4 Cc.) [6.5 M̄]; oil of nutmegs, one-fourth of a cubic centimeter (0.25 Cc.) [4 M̄]; oil of fennel, three-fourths of a cubic centimeter (0.75 Cc.) [12 M̄]; magnesium carbonate, fifteen grammes (15 Gm.) [231 grs.]; aromatic elixir (U. S. P.), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Triturate the oils with magnesium carbonate, and gradually add eight hundred and seventy-five cubic centimeters (875 Cc.) [29 fl̄, 282 M̄] of aromatic elixir. Shake occasionally during an hour, filter, and pass enough aromatic elixir through the filter to make eight hundred and seventy-five cubic centimeters (875 Cc.) [29 fl̄, 282 M̄] of filtrate. Add the fluid extract to the filtrate, mix, and filter, if necessary"—(*Nat. Form.*). Employed to mask the bitterness of quinine.

ELIXIR GUARANÆ (N. F.), *Elixir of guarana*.—*Formulary number*, 79: "Fluid extract of guarana (U. S. P.), two hundred cubic centimeters (200 Cc.) [6 fl̄, 366 M̄]; aromatic elixir (U. S. P.), two hundred cubic centimeters (200 Cc.) [6 fl̄, 366 M̄]; compound elixir of taraxacum

(F. 111), six hundred cubic centimeters (600 Cc.) [20 fl. 3, 138 M]. Mix them; allow to stand during 48 hours, if convenient, and filter. Each fluid drachm represents 12 grains of guarana"—(Nat. Form.).

ELIXIR HYPOPHOSPHITUM (N. F.), *Elixir of hypophosphites*.—*Formulary number*, 81: "Calcium hypophosphite, fifty-two and one-half grammes (52.5 Gm.) [1 oz. av., 373 grs.]; sodium hypophosphite, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; potassium hypophosphite, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; citric acid, four grammes (4 Gm.) [62 grs.]; water, two hundred and fifty cubic centimeters (250 Cc.) [8 fl. 3, 218 M]; and thirty cubic centimeters (30 Cc.) [1 fl. 3, 7 M]; compound spirit of cardamom, five cubic centimeters (5 Cc.) [1 fl. 3, 7 M]; aromatic elixir (U. S. P.), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]. Dissolve the hypophosphites in the water; then add the citric acid in the water; then add the glycerin, compound spirit of cardamom, and aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M], if necessary. Each fluid drachm contains 3 grains of calcium hypophosphite and 1 grain of sodium and potassium hypophosphite"—(Nat. Form.).

ELIXIR HYPOPHOSPHITUM CUM FERRO (N. F.), *Elixir of hypophosphites with iron*.—*Formulary number*, 82: "Calcium hypophosphite, twenty-five grammes (25 Gm.) [386 grs.]; sodium hypophosphite, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; potassium hypophosphite, eight and one-half grammes (8.5 Gm.) [131 grs.]; sulphate of iron, in clear crystals, four grammes (4 Gm.) [62 grs.]; citric acid, four grammes (4 Gm.) [62 grs.]; water, two hundred and fifty cubic centimeters (250 Cc.) [8 fl. 3, 218 M]; syrup (U. S. P.), two hundred cubic centimeters (200 Cc.) [8 fl. 3, 218 M]; aromatic elixir (U. S. P.), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]. Dissolve the hypophosphites in one hundred and seventy-five cubic centimeters (175 Cc.) [5 fl. 3, 440 M] of water; add the syrup. Dissolve the sulphate of iron in the remainder of the water, and mix this with the other solution. Then add three hundred and fifty cubic centimeters (350 Cc.) [11 fl. 3, 440 M] of aromatic elixir, set the mixture aside, in a cold place for 12 hours, and filter from the precipitated calcium sulphate. Finally, dissolve the citric acid in the filtrate, and pass the aromatic elixir through the filter to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]. Each fluid drachm contains about $\frac{1}{4}$ grain of hypophosphite of iron, $\frac{1}{4}$ grain each of the hypophosphites of calcium and sodium, and $\frac{1}{4}$ grain of potassium hypophosphite"—(Nat. Form.).

ELIXIR LITHII CITRATIS (N. F.), *Elixir of lithium citrate*.—*Formulary number*, 84: "Lithium citrate, eighty-five grammes (85 Gm.) [3 oz. av.]; aromatic elixir (U. S. P.), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]. Dissolve the citrate in about nine hundred cubic centimeters (900 Cc.) [30 fl. 3, 208 M] of aromatic elixir by agitation. Then add enough aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M], and filter. Each fluid drachm contains 5 grains of lithium citrate"—(Nat. Form.).

ELIXIR MALTI ET FERRI (N. F.), *Elixir of malt and iron*.—*Formulary number*, 86: "Malt, two hundred and fifty cubic centimeters (250 Cc.) [8 fl. 3, 218 M]; phosphate of iron (U. S. P.), seventeen and one-half grammes (17.5 Gm.) [270 grs.]; water, thirty cubic centimeters (30 Cc.) [1 fl. 3, 7 M]; aromatic elixir (U. S. P.), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]. Dissolve the phosphate of iron in the water by the aid of heat, mix the solution with the extract of malt previously introduced in a graduated bottle, and add enough aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]. Set the mixture aside for 24 hours, and filter. Each fluid drachm represents 1 grain of phosphate of iron, and 15 minims of extract of malt. *Note*.—The malt, most suitable for this preparation, should have about the consistence of Balsam of Capivi at a temperature of about 15° C. (59° F.)"—(Nat. Form.).

ELIXIR PEPSINI (N. F.), *Elixir of pepsin*.—*Formulary number*, 88: "Pepsin (U. S. P.), fifteen and one-half grammes (15.5 Gm.) [270 grs.]; hydrochloric acid (U. S. P.), four cubic centimeters (4 Cc.) [65 M]; glycerin, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl. 3, 109 M]; compound elixir of taraxacum (F. 111), sixty-five cubic centimeters (65 Cc.) [2 fl. 3, 95 M]; alcohol, one hundred and seventy-five cubic centimeters (175 Cc.) [5 fl. 3, 401 M]; purified talcum (F. 395), fifteen grammes (15 Gm.) [231 grs.]; sugar, two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.]; water, a sufficient quantity, to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]. Mix the pepsin with three hundred cubic centimeters (300 Cc.) [11 fl. 3, 401 M] of water, add the glycerin and acid, and allow until solution has been effected. Then add the compound elixir of taraxacum, and the purified talcum, and mix thoroughly. Set the mixture aside for a few hours, and agitate. Then filter it through a wetted filter, dissolve the sugar in the filtrate, and add enough water through the filter to make the whole product measure one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]. Each fluid drachm represents 1 grain of pepsin"—(Nat. Form.).

ELIXIR PEPSINI, BISMUTHI ET STRYCHNINÆ (N. F.), *Elixir of pepsin, bismuth and strychnine*.—*Formulary number*, 89: "Strychnine sulphate, one hundred and seventy-five milligrams (0.175 Gm.) [2.7 grs.]; elixir of pepsin and bismuth (F. 90), one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]. Dissolve the strychnine sulphate in the elixir. Each fluid drachm represents $\frac{1}{4}$ grain of strychnine sulphate, 1 grain of pepsin, and 2 grains of bismuth ammonium citrate"—(Nat. Form.). This execrable combination, in a pharmaceutical preparation, has been one of the most popular American elixirs. Possibly, its chief advantage rests in the minute amount of strychnine present, and the fact that the incompatible nature of the pepsin and bismuth precipitates the former and destroys the latter.

ELIXIR Pepsini et Bismuthi (N. F.), *Elixir of pepsin and bismuth.*—*Formulary number, 90:* "Pepsin (*U. S. P.*), seventeen and one-half grammes (17.5 Gm.) [270 grs.]; bismuth and ammonium citrate, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; water of ammonia (*U. S. P.*), a sufficient quantity; glycerin, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl. 3, 109 ml.]; alcohol, one hundred and seventy-five cubic centimeters (175 Cc.) [5 fl. 3, 441 ml.]; syrup (*U. S. P.*), two hundred and fifty cubic centimeters (250 Cc.) [8 fl. 3, 218 ml.]; compound elixir of taraxacum (*F. 111*), sixty-five cubic centimeters (65 Cc.) [2 fl. 3, 95 ml.]; purified talcum (*F. 395*), fifteen grammes (15 Gm.) [237 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 ml.]. Dissolve the pepsin in two hundred and fifty cubic centimeters (250 Cc.) [8 fl. 3, 218 ml.] of water. Dissolve the bismuth and ammonium citrate in sixty cubic centimeters (60 Cc.) [2 fl. 3, 14 ml.] of warm water, allow the solution to stand until clear, if necessary; then decant the clear liquid, and add to the residue just enough water of ammonia to dissolve it, carefully avoiding an excess. Then mix the two solutions, and add the glycerin, compound elixir of taraxacum, and alcohol. Thoroughly incorporate the purified talcum with the mixture, filter it through a wetted filter, and pass enough water through the filter to make the filtrate measure seven hundred and fifty cubic centimeters (750 Cc.) [25 fl. 3, 173 ml.]. To this add the syrup. Each fluid drachm represents 1 grain of pepsin, and 2 grains of bismuth and ammonium citrate"—(*Nat. Form.*).

ELIXIR Potassii Acetatis et Juniperi (N. F.), *Elixir of potassium acetate and juniper.*—*Formulary number, 96:* "Potassium acetate, eighty-five grammes (85 Gm.) [3 oz. av.]; fluid extract of juniper (*F. 164*), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl. 3, 109 ml.]; magnesium carbonate, fifteen grammes (15 Gm.) [231 grs.]; aromatic elixir (*U. S. P.*), a sufficient quantity, to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 ml.]. Triturate the fluid extract of juniper with the magnesium carbonate, then add seven hundred and fifty cubic centimeters (750 Cc.) [25 fl. 3, 173 ml.] of aromatic elixir in which the potassium acetate has previously been dissolved. Filter, and add enough aromatic elixir through the filter, to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 ml.]. Each fluid drachm represents 5 grains of potassium acetate and 7½ grains of juniper"—(*Nat. Form.*).

ELIXIR Rhamni Purshianæ (N. F.), *Elixir of rhamnus purshiana, Elixir of cascara sagrada.*—*Formulary number, 101:* "Fluid extract of rhamnus purshiana (*U. S. P.*), two hundred and fifty cubic centimeters (250 Cc.) [8 fl. 3, 218 ml.]; compound elixir of taraxacum (*F. 111*), seven hundred and fifty cubic centimeters (750 Cc.) [25 fl. 3, 173 ml.]. Mix them. Allow the mixture to stand a few days, if convenient, and filter. Each fluid drachm represents 15 grains of rhamnus purshiana"—(*Nat. Form.*).

ELIXIR Rhei (N. F.), *Elixir of rhubarb.*—*Formulary number, 103:* "Sweet tincture of rhubarb (*U. S. P.*), five hundred cubic centimeters (500 Cc.) [16 fl. 3, 435 ml.]; deodorized alcohol, sixty-five cubic centimeters (65 Cc.) [2 fl. 3, 95 ml.]; water, one hundred and eighty-five cubic centimeters (185 Cc.) [6 fl. 3, 123 ml.]; glycerin, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl. 3, 109 ml.]; syrup (*U. S. P.*), one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl. 3, 109 ml.]. Mix them and filter. Each fluid drachm represents about 2½ grains of rhubarb"—(*Nat. Form.*).

ELIXIR Rubi Compositum (N. F.), *Compound elixir of blackberry.*—*Formulary number, 105:* "Blackberry root, one hundred and sixty grammes (160 Gm.) [5 oz. av., 282 grs.]; galls, one hundred and sixty grammes (160 Gm.) [5 oz. av., 282 grs.]; cinnamon, Saigon, one hundred and sixty grammes (160 Gm.) [5 oz. av., 282 grs.]; cloves, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; mace, twenty grammes (20 Gm.) [309 grs.]; ginger, twenty grammes (20 Gm.) [309 grs.]; blackberry juice, recently expressed, thirty-seven hundred and fifty cubic centimeters (3750 Cc.) [128 fl. 3, 385 ml.]; syrup (*U. S. P.*), eighteen hundred and seventy-five cubic centimeters (1875 Cc.) [63 fl. 3, 192 ml.]; glycerin, eighteen hundred and seventy-five cubic centimeters (1875 Cc.) [63 fl. 3, 192 ml.]; diluted alcohol (*U. S. P.*), a sufficient quantity to make ten thousand cubic centimeters (10,000 Cc.) [16 O, 82 fl. 3, 86 ml.]. Reduce the solids to a moderately coarse (No. 40) powder, moisten it with diluted alcohol, and percolate it with this menstruum in the usual manner, until twenty-five hundred cubic centimeters (2500 Cc.) [84 fl. 3, 257 ml.] of percolate are obtained. To this add the blackberry juice, syrup, and glycerin, and mix thoroughly"—(*Nat. Form.*).

ELIXIR Sodii Salicylatis (N. F.), *Elixir of sodium salicylate.*—*Formulary number, 106:* "Sodium salicylate, eighty-five grammes (85 Gm.) [3 oz. av.]; aromatic elixir (*U. S. P.*), a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 ml.]. Dissolve the sodium salicylate in about eight hundred cubic centimeters (800 Cc.) [27 fl. 3, 25 ml.] of aromatic elixir, by agitation. Then add enough aromatic elixir to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 ml.], and filter, if necessary. This preparation should be freshly prepared, when required for use. Each fluid drachm contains 6 grains of sodium salicylate"—(*Nat. Form.*).

ELIXIR AROMATICUM (U. S. P.)—AROMATIC ELIXIR.

SYNONYM: *Simple elixir.*

Preparation.—"Compound spirit of orange, twelve cubic centimeters (12 Cc.) [195 ml.]; syrup, three hundred and seventy-five cubic centimeters (375 Cc.) [12 fl. 3, 327 ml.]; precipitated calcium phosphate, fifteen grammes (15 Gm.) [231 grs.]; deodorized alcohol, distilled water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 ml.]. To the compound spirit

of orange add enough deodorized alcohol to make two hundred and fifty centimeters (250 Cc.) [8 fl̄, 218 M]. To this solution add the syrup in portions, agitating after each addition, and afterwards add, in the same proportions, three hundred and seventy-five cubic centimeters (375 Cc.) [12 fl̄, 327 M] of distilled water. Mix the precipitated calcium phosphate intimately with the water, and then filter through a wetted filter, returning the first portions of the filtrate until a transparent liquid is obtained. Lastly, wash the filter with a mixture of one volume (1 vol.) of deodorized alcohol and three volumes (3 vol.) of distilled water, until the product measures one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M].—(U. S. P.).

Action and Medical Uses.—Carminative; generally employed as a cathartic agent.

ELIXIR PHOSPHORI (U. S. P.)—ELIXIR OF PHOSPHORUS

Preparation.—"Spirit of phosphorus, two hundred and ten cubic centimeters (210 Cc.) [7 fl̄, 48 M]; oil of anise, two cubic centimeters (2 Cc.) [1/8 fl̄, 28 M]; glycerin, five hundred and fifty cubic centimeters (550 Cc.) [18 fl̄, 287 M]; aromatic elixir, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. To the spirit of phosphorus, contained in a graduated bottle, add the oil of anise and glycerin, and mix them by repeatedly inverting the bottle, until they form a clear liquid. Then add aromatic elixir, in several portions, gently agitating after each addition, until a transparent liquid is obtained, and the product measures one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Keep the product in dark, amber-colored, well-stoppered bottles in a cool and dark place. Each cubic centimeter of elixir of phosphorus represents about 1/4 milligramme (0.00025 Gm.) of phosphorus"—(U. S. P.).

Action, Medical Uses, and Dosage.—(See *Phosphorus*). Dose, from 1 fluid drachm (equivalent to 1 1/16 to 1/8 grain of phosphorus).

EMPLASTRA.—PLASTERS.

Plasters are designed to be applied upon the skin or surface of the body. They are of much thicker consistence than cerates, require a certain degree of heat to soften them sufficiently for spreading, and are very adhesive when applied to any part of the body. They are intended to fulfil four indications, viz.: to give mechanical support or pressure to certain parts; to hold cut surfaces in position; to protect parts from atmospheric action; and to produce sedative, stimulant, or other therapeutical influences, according to the nature of the medicines associated with them. They are most usually composed of resins combined with wax and other substances, and frequently in combination with the oleo-stearate or palmitate of lead or lead plaster as a basis. Plasters should be prepared in a metallic vessel, as tin, or iron, which, in consequence of the uprising vapors, undergoes when heated, thereby augmenting their volume, should be considerably larger than required to hold the components of the plaster when in the unmelted condition. The heat should be continued no longer than is necessary to effect the proper amalgamation of the ingredients; and those of a volatile character should be added at as late a period during the cooling of the plaster as is consistent with their intimate combination with it. After having melted the wax and resinous substances, etc., together they should be strained while still hot to remove impurities, and, as the several articles required to form the plaster are added, the mass should be well stirred. Some plasters require to be stirred constantly till cold, while others are poured into cold water during their melting, and worked by the hands, kneading them until nearly cold, and then rolling them into cylindrical rolls, or sticks of various dimensions and shapes, according to the views of the operator. The cylinders are usually made by rolling the plaster on a hard, smooth surface, kept constantly wet during the operation. If some of the components of a plaster are soluble in water, they should not be worked in this fluid, but be allowed to cool, either in the vessel in which it is prepared, or in pans or cylinders made for the purpose. As the

of the air exerts an influence upon plasters, it is advisable to cover them with paper or tin-foil, in order to protect them as much as possible against this influence; and they should always be kept in dry and cool situations. Plasters should be hard and not adhesive, at atmospheric temperatures, and should not become too soft, but remain flexible and tenacious when exposed to the natural heat of the body. When a plaster softens under ordinary atmospheric warmth, it should be remelted, and more resin, or other of its solid constituents be added; if it is too firm, not being readily spread at a moderate heat, or not sufficiently adhesive when in contact with the body, a sufficient quantity of olive oil should be added upon remelting it.

Plasters are spread upon various materials in accordance with the object for which they are used. If they are designed to act as mechanical supports, to exclude atmospheric air, etc., white sheepskin is the best material; if they are to be applied to ulcers, to surfaces exposed by the removal of the skin, or to wounds for the purpose of holding the divided surfaces in close contact with each other, some softer material may be used, as muslin, etc. Sometimes oiled silk, or india-rubber cloth is employed, and where economy is desired, they are spread on stout paper. After cutting the leather somewhat larger than the size desired, paste strips of paper, about $\frac{1}{4}$ inch wide, along the edges of the leather, and after having spread the plaster within the space which they inclose, remove them. The plaster should be spread thinly and evenly, always leaving an unspread edge or border, $\frac{1}{4}$ inch wide, which serves to protect the linen worn over it from adhering to it. There are various modes of spreading the plaster; some melt the plaster in a suitable vessel over a gentle fire, and spread it by means of a common spatula; others use an iron instrument made expressly for the purpose, which, when properly heated, they apply to the plaster; as this melts, the fused portion is dropped upon various parts of the leather, and the spreading is accomplished by carefully passing the same heated iron over the surface, carrying portions of the melted plaster along with it. Care must be taken not to heat the irons employed in spreading to too great a degree, else certain parts of the plaster may become volatilized or decomposed. When it is desired to obtain large quantities of plasters, they are spread by machines made for the purpose, and these factory-made spread plasters are now such favorites as to have practically displaced those of the pharmacist.

Adhesive material spread upon silk, muslin, or paper, makes adhesive and court plasters, of which the official *Emplastrum Capsici* and *Emplastrum Ichthyocolæ* are examples. Such preparations are known in Europe under the name *sparradrap*. Porous plasters are those which have been closely perforated by means of a metal wheel beset with punches. Elegant plasters are now manufactured on a large scale by specialists who use rubber and other plaster bases.

The following plasters containing mercury are official:

EMPLASTRUM AMMONIACI CUM HYDRARGYRO (*U. S. P.*), *Ammoniac plaster with mercury*.—“Ammoniac, seven hundred and twenty grammes (720 Gm.) [1 lb. av., 9 ozs., 174 grs.]; mercury, one hundred and eighty grammes (180 Gm.) [6 ozs. av., 153 grs.]; oleate of mercury, eight grammes (8 Gm.) [123 grs.]; diluted acetic acid, one thousand cubic centimeters (1000 Cc.) [33 fl. 391 M.]; lead plaster, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lb. av., 3 ozs., 120 grs.]. Digest the ammoniac with the diluted acetic acid, in a suitable vessel, avoiding contact with metals, until it is entirely emulsified; then strain, and evaporate the strained liquid by means of a water-bath, stirring constantly, until a small portion, taken from the vessel, hardens on cooling. Triturate the oleate of mercury with the mercury gradually added, until globules of the metal cease to be visible. Next add, gradually, the ammoniac, while yet hot; and finally, having added enough lead plaster, previously melted by means of a water-bath, to make the mixture weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.], and mix the whole thoroughly”—(*U. S. P.*). This plaster frequently excites an eczematous eruption, and may produce pyalism. It is more active than plaster of mercury, and is used to discuss *symphilitic swellings*. It is not employed in Eclectic practice.

EMPLASTRUM HYDRARGYRI (*U. S. P.*), *Mercurial plaster*.—“Mercury, three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; oleate of mercury, twelve grammes (12 Gm.) [185 grs.]; lead plaster, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Triturate the mercury with the oleate of mercury in a tared capsule until globules of metal are no longer visible. Then place the capsule on a water-bath, add enough lead plaster, previously melted, to make the contents weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.], and mix the whole thoroughly”—(*U. S. P.*). Used as a counter-irritant and stimulating discutient to remove *symphilitic nodes*, *glandular swellings of syphilis*, *symphilitic engorgements of the liver*, and *splenic enlargements of malarial origin*. May produce sore gums and pyalism. Not employed in Eclectic medicine.

The U. S. P. of 1880 directed the following plasters, the amounts being those in the metric system as given in the *National Formulary*:

EMPLASTRUM AMMONIACI (N. F.) (U. S. P., 1880), *Ammoniac plaster*.—*Formulary number*, 116: "Ammoniac, one hundred grammes (100 Gm.) [3 oss. av., 231 grs.]; diluted acetic acid, one hundred and forty cubic centimeters (140 Cc.) [4 fl. 3, 352 fl.]. Digest the ammoniac with the diluted acetic acid, in a suitable vessel, avoiding contact with metals, until it is entirely emulsified; then strain and evaporate the strained liquid, by means of a water-bath, stirring constantly, until a small portion, taken from the vessel, hardens on cooling"—(*Nat. Form.*).

EMPLASTRUM GALBANI (N. F.) (U. S. P., 1880), *Galbanum plaster*.—*Formulary number*, 120: "Galbanum, sixteen grammes (16 Gm.) [247 grs.]; turpentine, two grammes (2 Gm.) [31 grs.]; burgundy pitch, six grammes (6 Gm.) [92 grs.]; lead plaster, seventy-six grammes (76 Gm.) [2 oss. av., 298 grs.]. To the galbanum and turpentine, previously melted together and strained, add, first, the burgundy pitch, then the lead plaster, melted over a gentle fire, and mix the whole thoroughly"—(*Nat. Form.*).

Galbanum plaster of the *British Pharm.* consists of 1 ounce (av.) each of galbanum, ammoniacum, and yellow wax, and 8 ounces (av.) of lead plaster. The galbanum and ammoniacum are melted together and strained, and subsequently the wax and lead plaster, also melted together, are added, and the whole mass thoroughly mixed together.

EMPLASTRUM GALBANI RUBRUM, or **EMPLASTRUM OXYCROCUM**.—The *German Pharmacopœia*, of 1872, directed the following plaster, much employed by the German people in America: Melt together, with moderate heat, 6 parts each of resin, burgundy pitch, and yellow wax; strain; now add to 3 parts of turpentine, 2 parts each of powdered ammoniac and galbanum. Add this solution to the first part. Next add to the whole mixture 1 part of powdered saffron, and 2 parts each of powdered mastic, olibanum and myrrh, all previously intimately mixed, and mix the whole mass together. An excellent stimulating plaster for local affections.

EMPLASTRUM PICIS CANADENSIS (N. F.) (U. S. P., 1880), *Canada pitch plaster*.—*Formulary number*, 121: "Canada pitch, ninety grammes (90 Gm.) [3 oss. av., 76 grs.]; yellow wax, ten grammes (10 Gm.) [154 grs.]. Melt them together, strain the mixture, and stir constantly until it thickens on cooling"—(*Nat. Form.*).

The following plasters are sometimes used:

EMPLASTRUM CERUSSÆ (*Emplastrum album coctum*), *White lead plaster*.—Lead plaster, 60 parts; olive oil, 10 parts. Melt together. Add lead carbonate (in fine powder), 35 parts. This, with the addition of a little water, as needed, is to be boiled until a plaster consistence is obtained. This is a German official plaster.

MAYN'S PLASTER resembles the preceding, excepting that it contains, in addition, powdered orris root and a small amount of wax.

EMPLASTRUM ACONITI.—ACONITE PLASTER.

Preparation.—Take of aconite root, in coarse powder, 4 troy ounces, moisten it with 6 fluid ounces of alcohol, sp. gr. 0.835, and permit it to macerate 24 hours; then put it in a displacer, and pour on gradually alcohol, sp. gr. 0.835, a sufficient quantity to make a pint of tincture. Distill off $\frac{3}{4}$ of the alcohol, evaporate the residue on a water-bath to a thick, syrupy consistence, then add lead plaster, in a melted state, $3\frac{1}{2}$ troy ounces, and stir constantly until it is properly incorporated with the soft resinous extract, and cools.

Description.—This forms a brown, homogenous mass, weighing about 4 troy ounces. It should, when used, be spread in a thin layer on skin or oiled-silk, and may be used several times when its application has not been too long continued at first. It is considered superior to that in which only aconite enters, being more uniform in its strength and of equal efficacy.

Action and Medical Uses.—It possesses the medicinal efficacy of the root, and has been found a valuable application in *neuralgia*, *headache*, *rheumatic pains*, *painful tumors of the breast* and other parts, and in *inflammatory dysmenorrhœa* (W. Procter, Jr.).

EMPLASTRUM ARNICÆ (U. S. P.)—ARNICA PLASTER.

Preparation.—"Extract of arnica root, three hundred and thirty grammes (330 Gm.) [11 oss. av., 280 grs.]; resin plaster, six hundred and seventy grammes (670 Gm.) [1 lb. av., 7 oss., 277 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 oss., 120 grs.]. Add the extract to the plaster, previously melted by means of a water-bath, and mix them thoroughly"—(*U. S. P.*).

Action and Medical Uses.—A stimulant, useful as an application to *painful or sprained joints*, *chronic rheumatic pains*, *weak back*, etc.

EMPLASTRUM AROMATICUM (N. F.)—AROMATIC PLASTER.

SYNONYM: *Spice plaster.*

Preparation.—*Formulary number, 117:* "Cloves, ten grammes (10 Gm.) [154 grs.]; cinnamon, Saigon, ten grammes (10 Gm.) [154 grs.]; ginger, ten grammes (10 Gm.) [154 grs.]; capsicum, five grammes (5 Gm.) [77 grs.]; camphor, five grammes (5 Gm.) [77 grs.]; cotton seed oil, thirty-five grammes (35 Gm.) [1 oz. av., 102 grs.]; lead plaster, twenty-five grammes (25 Gm.) [386 grs.]. Melt together the lead plaster and cotton seed oil, with the aid of heat. Cool the mixture and, while it is still soft, thoroughly incorporate with it the aromatic ingredients, previously reduced to a very fine powder"—(*Nat. Form.*).

Action and Medical Uses.—This is an excellent stimulating application for the relief of *local pains*, especially of the chest and abdomen, and to palliate the pains of *rheumatism* and *neuralgia*.

EMPLASTRUM BELLADONNÆ (U. S. P.)—BELLADONNA PLASTER.

Preparation.—"Alcoholic extract of belladonna leaves, two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.]; resin plaster, four hundred grammes (400 Gm.) [14 ozs. av., 48 grs.]; soap plaster, four hundred grammes (400 Gm.) [14 ozs. av., 48 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Melt the plasters on a water-bath; then add the extract of belladonna leaves, and continue the heat, stirring constantly, until a homogeneous mass results"—(*U. S. P.*). For uses, see *Belladonna*.

EMPLASTRUM BELLADONNÆ COMPOSITUM.—COMPOUND PLASTER OF BELLADONNA.

Preparation.—Take of resin plaster, 5 troy ounces; alcoholic extract of belladonna root, 1 troy ounce; alcoholic extract of conium maculatum, $1\frac{1}{2}$ troy ounces; pulverized iodine, 40 grains. Place the plaster in an earthenware mortar, and put this in hot water. When the plaster commences to melt, add the extracts of belladonna and conium, and rub the ingredients well together; then take the mortar from the water-bath, continuing the trituration, and, when nearly cool, add the iodine. The inspissated juices of the above narcotics are preferable to the ordinary extract in preparing this plaster.

Action and Medical Uses.—This plaster may be used for the same purposes as the belladonna plaster, and is also an excellent application over *scrofulous* and other *tumors*, *white-swelling*, and *goitre*; and may likewise be applied over the region of the liver and spleen for chronic affections of these organs, and over the lumbar vertebræ in severe *dysmenorrhœa*. Like the preceding plaster, it occasionally affects the constitution, and then requires to be omitted for a few days (J. King).

EMPLASTRUM CAPSICI (U. S. P.)—CAPSICUM PLASTER.

SYNONYM: *Sparadrapum capsici.*

Preparation.—"Oleo-resin of capsicum, resin plaster, each, a sufficient quantity. Melt the resin plaster at a gentle heat, spread a thin and even layer of it upon muslin, and allow it to cool. Then, having cut off a piece of the required size, apply a thin coat of oleo-resin of capsicum, by means of a brush, leaving a narrow, blank margin along the edges. A space of ten centimeters (10 Cm.) [3.94 inches] square should contain about twenty-five centigrammes (0.25 Gm.) [3.85 grains] of oleo-resin of capsicum"—(*U. S. P.*).

Action and Medical Uses.—This plaster is stimulant and slightly rubefacient. It may be applied where a mild counter-irritant is needed in *neuralgic*, *rheumatic*, and other *painful conditions*.

EMPLASTRUM CAPSICI COMPOSITUM.—COMPOUND CAPSICUM PLASTER.

SYNONYMS: *Common strengthening plaster, Sear-cloth plaster.*

Preparation.—Take of rosin, 4 troy ounces; yellow wax, 1 troy ounce; tincture of capsicum, $\frac{1}{2}$ pint. Melt the rosin and wax, and add the tincture stirring by a gentle heat, until the alcohol is evaporated; then remove from fire, and when nearly cold, add pulverized camphor, $\frac{1}{2}$ troy ounce; oil of cloves, 45 minims. Stir until cold (*Beach's Amer. Prac.*).

Action and Medical Uses.—This forms a gently stimulating and strengthening plaster, and may be used in all cases where artificial support, prevention of contact of atmospheric air, or mild stimulation is required. It was a favorite with Eclectic physicians 25 years ago, and is still extensively used by them.

EMPLASTRUM FERRI (U. S. P.)—IRON PLASTER.

SYNONYMS: *Strengthening plaster, Emplastrum ferratum, Chalybeate plaster, plastrum martiale, Emplastrum roborans.*

Preparation.—“Ferric hydrate, dried at a temperature not exceeding (176° F.), ninety grammes (90 Gm.) [3 oz. av., 76 grs.]; olive oil, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; burgundy pitch, one hundred and forty grammes (140 Gm.) [4 ozs. av., 411 grs.]; lead plaster, seven hundred and twenty grammes (720 Gm.) [1 lb. av., 9 ozs., 174 grs.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Melt the lead plaster and burgundy pitch by means of a water-bath, and add the olive oil; then add the ferric hydrate, and stir constantly until the mixture thickens on cooling”—(*U. S. P.*).

Action and Medical Uses.—This plaster is stimulating, protective, and supporting. It is applied to the chest during the latter stage of *pleurisy*, to give *enlargements*, and to *rheumatic joints and muscles*. It is sometimes applied to *backs*. It has nothing in particular to recommend it.

EMPLASTRUM ICHTHYOCOLLÆ (U. S. P.)—ISINGLASS PLASTER.

SYNONYMS: *Court plaster, Sparadrapum adhaesivum, Taffetas adhaesivum, Emplastrum adhaesivum anglicum, Sericum anglicum.*

Preparation.—“Isinglass, ten grammes (10 Gm.) [154 grs.]; alcohol, grammes (40 Gm.) [1 oz. av., 180 grs.]; glycerin, one gramme (1 Gm.) [15 grs.]; water, tincture of benzoin, each, a sufficient quantity. Dissolve the isinglass in a sufficient quantity of hot water to make the solution weigh one hundred and twenty grammes (120 Gm.) [4 ozs. av., 102 grs.]. Spread one-half of this, in successive layers, upon taffeta (stretched on a frame), by means of a brush, waiting after each application until the layer is dry. Mix the second half of the isinglass with the alcohol and glycerin, and apply it in the same manner. Then coat the taffeta, coat it on the back with tincture of benzoin, and allow it to be perfectly dry. Cut the plaster in pieces of suitable length and preserve them in well-closed vessels. The above-directed quantities are sufficient to cover a piece of taffeta thirty-eight centimeters (38 Cm.) [about 16 inches] square”—(*U. S. P.*). The glycerin is added to this plaster to give it pliability, while the benzoin makes it partially water-proof. Pharmacists now purchase all their court plaster from plaster manufacturers.

Action and Medical Uses.—This is the ordinary isinglass plaster employed for covering minor injuries, as *abrasions, slight cuts, pimples*, etc. It should be applied by moistening it with clean water, and never with saliva.

Related Preparations.—**GELANTHUM.** Gelanthum is a kind of varnish of the isinglass class, having about the consistency of Unguentum Glycerini. It was devised by Dr. Unna, and is made by W. Mielck in Hamburg, apothecary of the Schwanen-Apotheke, who is also proprietor of the copyrighted name Gelanthum. Unna endeavored to find a vehicle

would allow the fixing of the various medicaments upon the skin, and which would be capable of drying quickly. This he at last accomplished by means of a combination of gelatin and tragacanth. Unguentum Caseini, which has hitherto been considered the best substance for this purpose, does not possess the property of absorbing all medicaments without decomposition, nor does it keep for an indefinite length of time. Nevertheless, Unna states that, in certain cases, unguentum caseini is preferable to gelanthum, since the casein salve is a better medium for carrying the different kinds of tar, and since casein itself exerts a beneficial influence in the case of thickening of the epidermis.

Preparation of Gelanthum.—The tragacanth, in pieces, is to be treated with 20 times its weight of cold water for 3 to 4 weeks, with frequent agitation; then heated over steam for one day, and pressed through cheese cloth. The gelatin likewise is swollen in cold water (4 to 5 parts), exposed for some time to steam under pressure, in order to deprive it of the tendency to gelatinize, and is then filtered through a steam filtering funnel. This filtrate is mixed with the tragacanth mucilage and the mixture heated for about 2 days in a steam bath, again strained, and finally mixed with 5 per cent of glycerin, some rose water (preferably a few drops of oil of rose), and thymol (2:10,000). The finished gelanthum contains about 2 per cent each of gelatin and tragacanth. This gelanthum may safely be mixed with as much as 50 per cent of ichthyol, 40 per cent salicylic acid, resorcin and pyrogallol, 5 per cent carbolic acid, or 1 per cent mercuric chloride without impairing its qualities as a varnish. Incompatibles incorporated into gelanthum are said not to act upon each other, still it is recommended to first triturate them, if in powder form, or as a viscid liquid, with water or spirits as the case may require; fats and oils should first be emulsified by means of gum Arabic. An addition of 20 per cent glycerin, or of 40 per cent ichthyol does not affect the drying qualities of gelanthum.

GELANTHE CRÈME is a preparation introduced by the Schwanen-Apotheke in Hamburg as a cosmetic, and consists of 10 per cent of fat and some perfume admixed with gelanthum (*Pharm. Centralhalle*, 1896, pp. 183 and 815).

EMPLASTRUM MENTHOL.—MENTHOL PLASTER.

Preparation.—Melt together resin, 7 ounces (av.), and yellow wax, 1 ounce (av.). Stir into the mixture, as it cools, menthol, 2 ounces (av.).

Action and Medical Uses.—This plaster is now official in the *Br. Pharm.* It is designed as a counter-irritant, and is used for *local pains, neuralgic or rheumatic* in character, and in *migraine*.

EMPLASTRUM MYRICE.—BAYBERRY PLASTER.

SYNONYM: *Green salve.*

Preparation.—Take of white gum turpentine and bayberry wax, each 2 troy ounces. Melt together, strain, and stir till cold. In winter a small quantity of olive oil may be added (*Beach's American Practice*).

Action and Medical Uses.—This forms a very valuable and efficient application to *scrofulous* and other *ulcers*; also to many *cutaneous affections*. It is often prepared of the consistence of an ointment for these purposes (see *Bayberry Ointment*).

EMPLASTRUM OPII (U. S. P.)—OPIUM PLASTER.

SYNONYMS: *Emplastrum odontalgicum, Emplastrum cephalicum, Emplastrum opiatum.*

Preparation.—“Extract of opium, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; burgundy pitch, one hundred and eighty grammes (180 Gm.) [6 ozs. av., 153 grs.]; lead plaster, seven hundred and sixty grammes (760 Gm.) [1 lb. av., 10 ozs., 355 grs.]; water, eighty cubic centimeters (80 Cc.) [2 fl. oz., 339 m.]; to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Rub the extract of opium with the water until it is uniformly soft, and add it to the burgundy pitch and lead plaster melted together by means of a water-bath; then continue the heat for a short time, stirring constantly, until the moisture is evaporated”—(*U. S. P.*).

Action and Medical Uses.—This plaster is designed as an application to fulfil many of the purposes for which opium is used externally, as for the relief of *painful parts*, as in *rheumatism, neuralgia, odontalgia*, etc.

EMPLASTRUM PICIS BURGUNDICÆ (U. S. P.)—BURGUNDY PITCH PLASTER.

Preparation.—"Burgundy pitch, eight hundred grammes (800 Gm. av., 12 ozs., 96 grs.); olive oil, fifty grammes (50 Gm.) [1 oz. av., 334 grs.], wax, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Melt together the pitch and yellow wax, then incorporate the olive oil, and constantly until the mass thickens on cooling"—(U. S. P.).

Action and Medical Uses.—This plaster is stimulant, and may be used where a mild counter-irritant is demanded, as well as for a strengthening supporting plaster. Occasionally the pitch plaster will be found to cause, set up a discharge of serum, and when it does so, it should be often renewed.

EMPLASTRUM PICIS CANTHARIDATUM (U. S. P.)—CANTHARID PITCH PLASTER.

SYNONYMS: *Warming plaster, Warm plaster.*

Preparation.—"Cerate of cantharides, eighty grammes (80 Gm.) [2 ozs., 360 grs.]; burgundy pitch, a sufficient quantity to make one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]. Melt the cerate of cantharides on a water bath containing boiling water, and continue the heat for 15 minutes; then strain it through a piece of muslin of close texture so that the cantharides will be retained on the muslin. To the strained liquid add a sufficient quantity of burgundy pitch to make the whole weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; render the mixture homogeneous by stirring, remove the heat, and stir the mass until it thickens on cooling"—(U. S. P.).

It is necessary that the cantharides be in very fine powder. The direct strain the cerate through muslin is very essential, that none of the particles of cantharides of any considerable size may come in contact with the skin and vesiculate.

Action and Medical Uses.—This plaster is a mild counter-irritant, and is considered useful in *chronic articular diseases, chronic rheumatism, and such diseases as chronic bronchitis, chronic pleurisy, and in pulmonary engorgement of a local character.* Also applied in *phthisis, asthma, whooping-cough, bronchitis, hepatitis, etc.*

EMPLASTRUM PICIS COMPOSITUM.—COMPOUND TAR PLASTER.

SYNONYMS: *Irritating plaster.*

Preparation.—Take Burgundy pitch, 24 troy ounces; white turpentine, 24 troy ounces; melt them together, add tar 48 troy ounces, stir well together, strain, remove from the fire, and add finely-powdered mandrake root, blood-poke-root, Indian turnip, each 10 troy ounces. Incorporate well together (Morrow). When it is desired to produce a more active preparation, and one that will act more promptly, euphorbium, in powder, 4 troy ounces, is added to the mass.

Action and Medical Uses.—This plaster is irritant, rubefacient, and vesicative. It is used extensively in many cases where counter-irritation or revulsion is indicated, in *neuralgia, rheumatism, and in the majority of chronic diseases.* It acts more efficiently, and is much more adhesive when spread quite thin, on soft leather, than when spread on any kind of cloth; therefore it may be spread on oil-silk, india-rubber cloth, or other substance that will not be injured by any portion of it. This plaster may be held in place by a bandage or tape, but it has to be removed daily, but when it is desired to have a firmer adhesion to the skin, some adhesive plaster may be applied around the margin left on the surface upon which the tar plaster is spread. When applied to a part of the body it must be removed daily, for the purpose of thinly respreding the same on fresh leather, or oil-silk, etc., with the plaster, which is to be immediately reapplied upon the part. This course is to be continued until the surface, to which

applied, commences discharging matter, after which it should be removed 2 or 3 times a day, wiping it quite dry each time before respreding it, and likewise carefully drying the sore as much as possible. This latter is best accomplished by lightly pressing upon it soft pieces of dry cotton, linen, or lint, so as to absorb all the pus. The practitioner must bear in mind that he is never, no matter what may be the condition of the sore or surrounding parts, to wet it; this will render it irritable and inflamed, and cause it to cease suppurating healthily, and even to require its immediate healing.

This plaster is very painful, producing more or less irritability of the system, and should never be used except when its use is indispensable; when it becomes very painful and irritating, depriving the patient of sleep, or causing him to complain loudly, it must be removed, and a slippery-elm poultice be applied. Many practitioners consider the disturbance of sleep, alone, as an indication for removing the plaster, which may be reapplied when it is desirable to continue the suppurative discharge for a longer time, as soon as the elm poultice has allayed the local irritation. If this is not required, the sore may be healed by some simple application, as simple cerate, a mixture of beeswax and tallow, red oxide of lead plaster, etc. Whenever the tar plaster or the dressing to the sore produced by it, are removed for renewal, the sore should each time be cleansed from matter in the manner referred to above. As the peculiar odor of the ingredients of this plaster may be observed in the excretions, there is no doubt but that they are absorbed into the system, and exert an alterative as well as a counter-irritating influence.

EMPLASTRUM PLUMBI (U. S. P.)—LEAD PLASTER.

SYNONYMS: *Diachylon plaster*, *Emplastrum diachylon simplex*, *Litharge plaster*, *Emplastrum album coctum*.

Preparation.—"Lead oxide, three thousand two hundred grammes (3200 Gm.) [7 lbs. av., 384 grs.]; olive oil, six thousand grammes (6000 Gm.) [13 lbs. av., 3 ozs., 282 grs.]; water, a sufficient quantity. Mix the lead oxide, previously passed through a No. 80 sieve, intimately with about $\frac{1}{2}$ of the olive oil, by trituration, and add the mixture to the remainder of the oil contained in a bright copper boiler of a capacity equal to at least 4 times the bulk of the ingredients. Then add one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M.] of boiling water, and boil the whole together, over a fire, constantly stirring with a wooden spatula, until a small portion, when dropped into cold water, is found to be pliable and tenacious. From time to time add a little water to replace that lost by evaporation. When the contents of the boiler have acquired a whitish color and are perfectly homogeneous, transfer them to a vessel containing warm water, and as soon as the mass has sufficiently cooled, knead it well with the water so as to remove the glycerin, renewing the water from time to time, as long as it may be necessary. Finally divide the mass into rolls of suitable size"—(U. S. P.).

In the method here given, the formation of the plaster is rapid when the oxide of lead is in fine powder. Stirring facilitates the combination, by intimately mixing the particles, and preventing the oxide from adhering to the bottom of the vessel. To a practiced pharmacist the tenacity and consistence of the mass indicates when the reaction is complete. The reaction here involved, which is that of ordinary saponification, requires the addition of water as an indispensable ingredient, in order to make the formation of glycerin possible, as will be seen from the following equation which takes into account pure *olein* only: $2C_{18}H_{33}O_2(olein) + 3PbO(lead\ oxide) + 3H_2O(water) = 3Pb(C_{18}H_{31}O_2, lead\ oleate) + 2C_{18}H_{35}(OH)_2(glycerin)$.

Description and Tests.—Lead plaster, or *diachylon*, as it is frequently termed, is a grayish-white body, brittle when cold, plastic when warm, insoluble in water or alcohol, and partially soluble in ether. In the official description it is described as yellowish-white, but as a rule it is evenly grayish-white, unless old, when it changes on the surface to a yellowish or light-brownish hue. We have seen this plaster of a decidedly green color from the employment of "virgin" or the green olive oil. "A yellowish-white, pliable, and tenacious, but not greasy mass, gradually acquiring a brownish tint on the outside. On treating 5 Gm. of lead plaster

with 25 Co. of benzol, a somewhat viscid and slightly turbid solution will be formed, which will separate into a clear and a gelatinous layer after some time, but it should not deposit any sediment (absence of uncombined lead oxide).—(U.S.P.)

Action and Medical Uses.—Lead plaster is chiefly used as a basis for plasters. It is used in surgery on account of its adhesiveness and mildness of action, rarely causing irritation. It is used to keep the edges of wounds together, and as an application to *blistered and chafed surfaces*, and occasionally to some other parts of which it serves to protect from atmospheric influence. The sedative action of the lead used in its formation, probably assists its beneficial action.

An ointment is in considerable use as a dressing for *burns, scalds, and blains*, and various *cutaneous affections* accompanied with a burning or stinging sensation. It is prepared as follows: "Take of lead plaster, 24 troy ounces; melt it by a gentle heat, and, when melted, add to it oil of turpentine, 9 fluid ounces; linseed oil, 3 fluid ounces; oil of origanum, 16 fluid ounces; tincture of benzoin, 3 fluid ounces. Stir the articles constantly until the mass has sufficiently thickened. This is applied by completely and thickly covering the affected part with the ointment, over which a layer of raw cotton is to be placed, and allowed to remain until the part is well. In the case of deep burns, should the pain return after a few hours, the ointment should be removed, softening it with some warm water, and a cataplasm of elm bark, or flax seed, be applied. It is said to afford relief. Should the burn be extensive, care must be taken not to apply the ointment over the whole of it, but only over a portion at a time. This old ointment we have recognized under a fanciful proprietary name, extolled to the regular profession as a wonderful remedy for burns.

EMPLASTRUM PLUMBI IODIDI.—IODIDE OF LEAD PLASTER

Preparation.—Take lead iodide, 1 part (2 ounces av.); lead plaster (1 pound av.); resin, 1 part (2 ounces av.). Melt the resin and lead plaster at the lowest possible temperature, add the lead iodide, in fine powder, and mix thoroughly. This accords with the *Br. Pharm.*

Action and Medical Uses.—Discutient. Useful application for *arthritic affections*, and for topical use on *indurations*, the result of *inflammations*.

EMPLASTRUM PLUMBI OXIDI RUBRUM.—RED OXIDE OF LEAD PLASTER.

SYNONYM: *Black salve.*

Preparation.—Take of olive oil, 1 quart; rosin, beeswax, each, 1 troy ounce. Melt together in a capacious iron kettle and raise the mixture nearly to the decomposition point; then gradually add pulverized red lead, 12 troy ounces. Stir constantly; when the lead is taken up by the oil, the mixture becomes dark or shining black; then remove from the fire, and when nearly cold add oil of turpentine, 80 grains. It should not be removed from the fire until the consistency is such that it may be spread easily, which may be ascertained by spreading small portions of it from time to time, on a knife, and testing this when cold. (Beach's *American Practice*).

This is practically the old *Nuremberg plaster* of the *German Pharmacopoeia*, the formula for which is as follows: Take of red lead, 8 troy ounces; olive oil, 1 quart; mix, and expose to a heat until the mixture assumes a blackish appearance, and then add rosin, $\frac{1}{2}$ troy ounce; yellow wax, $1\frac{1}{2}$ troy ounces; camphor, 2 drachms; stir thoroughly together.

In the preparation of this plaster it must be remembered that oil of turpentine requires a heat of about 315.5° C. (600° F.) for ebullition; and should but be observed when the heat is only 100° C. (212° F.), it will probably be owing to the presence of water. If the oil itself is not brought nearly to the boiling point, the red lead will not be acted upon; hence, the operator should not add the oil until it has been so far heated as to scorch a feather when dipped into it. Similar preparations similar to these have been employed from time to time, one of them the *Universal*, or *Breast plaster*, often sold as a secret nostrum under various names.

It is made by boiling together, with constant stirring, red oxide of lead (in fine powder), 2 parts, and olive oil, 4 parts. When the melted mass has assumed a deep-brown color, add yellow wax, 1 part. This constitutes the *Emplastrum fuscum*, *Emplastrum matris fuscum*, *Emplastrum novicum*, *Emplastrum nigrum*, etc. Camphor (1 per cent) added to the above produces the *Emplastrum fuscum camphoratum* of the Germans.

Action and Medical Uses.—This is a valuable application in burns, many cutaneous affections, and syphilitic, scrofulous, fistulous, and all other species of ulcers. A preparation similar to the above is employed by many practitioners in preference. It is made as follows: Heat 2 quarts of linseed oil until it will scorch a feather; then gradually add 16 troy ounces of red lead in powder; when the red lead is taken up by the oil, and the mixture is black, remove from the fire, and when nearly cold add 2 troy ounces of oil of turpentine, and stir until the mixture is cold.

Related Preparation.—EMPLASTRUM FUSCUM CAMPHORATUM (N. F.), *Camphorated brown plaster*, *Emplastrum matris camphoratum*, *Camphorated mother plaster*.—Formulary number, 119: "Red oxide of lead, three hundred grammes (300 Gm.) [10 ozs. av., 255 grs.]; olive oil, six hundred grammes (600 Gm.) [1 lb. av., 5 ozs., 72 grs.]; yellow wax, one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]; camphor, ten grammes (10 Gm.) [154 grs.]. Triturate the red oxide of lead with a portion of the oil in a capacious copper kettle until a smooth paste results. Then add the remainder of the oil, excepting a small quantity required for trituration with the camphor, and boil the whole over a naked fire, under constant stirring, until gas bubbles rise, or until the red color of the mixture begins to turn brown. Then moderate the heat, but continue the stirring until the mixture has acquired a dark-brown color, and from time to time allow some drops of it to fall into cold water to test its consistence. When this is satisfactory, remove the vessel from the fire, add the wax in small pieces, and finally the camphor, previously rubbed to a smooth paste with a little olive oil. Mix thoroughly, allow the mixture to become somewhat cool, and while it is still warm, pour the plaster into paper molds, previously coated with mucilage, containing about 5 per cent of glycerin, and dried. Note.—This preparation is official in the German Pharmacopœia"—(Nat. Form.). The preceding closely resembles the Eclectic black salve.

EMPLASTRUM RESINÆ (U. S. P.)—RESIN PLASTER.

SYNONYMS: *Adhesive plaster*, *Sticking plaster*.

Preparation.—"Resin, in fine powder, one hundred and forty grammes (140 Gm.) [4 ozs. av., 411 grs.]; lead plaster, eight hundred grammes (800 Gm.) [1 lb. av., 12 ozs., 96 grs.]; yellow wax, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; to make one thousand grammes (1000 Gm.); [2 lbs. av., 3 ozs., 120 grs.]. Melt the lead plaster and yellow wax together with a gentle heat, then add the resin, and, when it is melted, mix the mass thoroughly"—(U. S. P.).

This preparation, when spread on muslin, forms the ordinary *Adhesive plaster*; as age impairs its adhesiveness, fresh supplies should be obtained frequently. Sometimes powdered Castile soap is added to it, which increases its plasticity without diminishing its adhesiveness, and renders it less brittle in winter. If a small band of adhesive plaster be used as though it were paper, the writing being made on its reverse side, then warmed and placed upon a bottle, it will form an excellent label for vessels kept in cellars and damp places. In place of ink, varnish may be used, colored with vermilion, and then both ink and label resist the action of water and moisture.

Action and Medical Uses.—This plaster is more irritating, as well as more adhesive than *Lead plaster*. It is used in surgery to hold the edges of wounds together, to keep the dressings of ulcers, etc., in place, to make pressure upon, or give support to parts, and for the same purposes as the lead plaster. It is sufficiently irritating in its composition, without having any other stimulating agents combined with it.

EMPLASTRUM RESINÆ COMPOSITUM.—COMPOUND RESIN PLASTER.

SYNONYM: *Adhesive and Strengthening plaster*.

Preparation.—Take of white resin, 12 troy ounces; yellow wax, burgundy pitch, tallow, of each, 1 troy ounce. Melt together, and add olive oil, pulverized,

camphor, and sassafras oil, of each, 1 drachm; West India rum, 1 fluid ounce. Incorporate well together, then pour the whole into cold water, and work with hands until cold, forming it into rolls or sticks (Beach's *American Practice*).

Action and Medical Uses.—This forms an adhesive and strengthening plaster, used in *rheumatism, weakness of the joints, wounds, ulcers, etc.* It is possessed of considerable stimulating property, and has been frequently used by practitioners; yet, notwithstanding, it is an unscientific preparation, as the rum and turpentine are not bound to unite readily. The *Emplastrum Capsici Compositum*, is a much better article to use for the same purposes.

EMPLASTRUM SAPONIS (U. S. P.)—SOAP PLASTER

Preparation.—“Soap, dried and in coarse powder, one hundred grammes (100 Gm.) [3 ozs. av., 23½ grs.]; lead plaster, nine hundred grammes (900 Gm.) [1 lb. av., 15 ozs., 327 grs.]; water, a sufficient quantity. Rub the soap with enough water to reduce it to a semi-liquid state; then mix it with the least quantity of lead plaster previously melted, and evaporate to the proper consistence”—(*U. S. P.*). It is important that the soap be in powder form, in order to insure a perfect union with water, and that the water be afterward evaporated, so that the plaster possess good adhesive qualities.

Action and Medical Uses.—This plaster, spread on leather, is used as a nutritive and mechanical support. It will be found very useful as an application for constant wear, to aid in softening and removing corns, after they have been carefully shaved down. The addition of iodine and camphor will greatly increase its utility in this respect.

EMPLASTRUM SAPONIS FUSCUM.—BROWN SOAP PLASTER

SYNONYMS: *Emplastrum cerati saponis, Soap cerate plaster.*

Preparation.—Boil together by means of a steam bath, lead oxide, 15 grains (av.), and vinegar, 1 gallon (Imp.), with constant stirring, until the acid and oxide combine. Add powdered curd soap, 10 ounces (av.), and again boil the mixture until the greater portion of the moisture is dissipated. Lastly, add yellow wax, 12½ ounces (av.), and olive oil, 1 pint (Imp.), previously melted. With constant stirring maintain the heat until the remaining moisture has been sufficiently evaporated to give a plaster consistence to the product. This preparation is in reality a cerate, and is the same as the *Ceratum Saponis Compositum* of the *London Pharmacopœia*. A similar preparation is that of the *U. S. P.* (1870). It allows: Take of soap plaster, 2 troy ounces; white wax, 2½ troy ounces; olive oil, 4 troy ounces. Melt together the plaster and the wax, add the oil, and after continuing the heat a short time, stir the mixture until cool—(*U. S. P.*, 1870).

Gerrard proposes the substitution of acetic acid (18 ounces) in place of vinegar. This quickens the process by shortening the time required for boiling.

Action and Medical Uses.—This plaster is employed where a cooling and nutritive cerate is desired. It is adapted to *chronic inflammatory swellings, as of the joints, arthritic enlargements, etc.* It also serves as an adhesive plaster.

EMULSA.—EMULSIONS.

The class emulsions comprises milk-like mixtures of liquids and solid bodies in a common menstruum. The agents chiefly employed to emulsify fixed oils are the galls of acacia, tragacanth, chondrus, dextrin, yolk of egg, and sometimes the tincture of quillaja; the latter, however, is somewhat toxic. Emulsions made with yolk of egg do not keep well. Acacia enters into the composition of most emulsions. Solutions of pancreatin or liquor potassæ are rarely used. Emulsions of fixed oils may be made by rubbing the oil with some solid intended as an impalpable powder or with sugar, syrup, or glycerin. If it be such an oil as oil of turpentine,

emulsion may be improved by first mixing it with an equal bulk of a fixed oil, as olive oil, oil of sweet almond, or oil of sesamum, and afterwards proceeding as with the fixed oils. With the resins suspension is effected by means of mucilages; with the gum-resins water only is required, inasmuch as the mucilage thus formed by the gummy material of the gum-resin holds the resinous particles in suspension. Emulsions prepared by means of an alkaline emulsifier precipitate upon the addition of acids; emulsions prepared with mucilages or with the yolk of egg are precipitated by the addition of an excess of saline or alcoholic preparations, such as tinctures, wines, or fluid extracts. Emulsions, if properly prepared will not "crack," i. e., separate into oil and water upon standing. The *National Formulary* gives the following general directions for the preparation of emulsions:

EMULSIONES (N. F.), *Emulsions*.—*Formulary number*, 123: "The successful formation of emulsions, whether of fixed or volatile oils, is most satisfactorily and expeditiously accomplished with acacia as the emulsifying agent. Hence, preference is given acacia in this Formulary, though other emulsifying agents are not ignored, and their use and application is exemplified in a number of alternative formulas for preparing emulsion of cod-liver oil.

A. Emulsification.—"When acacia is used as the emulsifying agent, it is important that the oil, the acacia, and the water, shall primarily be in absolutely definite proportion to each other *by weight*. This proportion is 8 parts of oil to 2 parts of acacia, and 3 parts of water. The oil (8), and acacia (2), in fine powder, are weighed into a mortar, and well mixed by trituration; the water (3), is then added *in one portion*, and the whole is triturated briskly until a thick, creamy emulsion is produced, the sides of the mortar being carefully scraped, and the mixture again triturated so as to insure the complete emulsification of all the oil. During warm weather, the water and oil should be cooled. The other ingredients may then be gradually added; first the flavoring, then the greater part of the water necessary to make the final quantity, then the syrup, etc. Finally, the quantity is adjusted by the addition of sufficient water. Alcoholic liquids should be added last, and should be previously mixed with a portion of the water. If these simple conditions and directions are carefully observed, and particularly, if the proportions by weight are accurate, a perfect emulsion is obtained with certainty and rapidity.

"With other emulsifying agents—mucilage of Irish moss, mucilage of dextrin, glycerite of egg, tincture of quillaja—the proportions need not be adjusted with the same minuteness. It suffices to place the emulsifier into a bottle or mortar, and to add the oil in small portions at a time, shaking or triturating briskly after each addition until emulsification is completed. Obviously, the preparation of this class of emulsions is very much facilitated by mechanical contrivances that are capable of producing brisk agitation and mingling of the two fluids, and such are necessarily resorted to when emulsions are to be made in large quantities for the market.

B. Flavoring.—"Since no single or compound aromatic can be devised which would be acceptable under all circumstances as a flavoring for emulsion of cod-liver oil, the selection of the most suitable aromatic must be left to the prescriber or dispenser. Among those which are found to be most serviceable are the following, the quantities given below being intended for one thousand cubic centimeters (1000 Cc.) [33 fl. oz., 391 M.] of finished emulsion, though in some cases a smaller or a larger quantity, in the same proportion, may be preferable:

(1) *Oil of gaultheria*, four cubic centimeters (4 Cc.) [65 M.]. (2) *Oil of gaultheria*, two cubic centimeters (2 Cc.) [32.5 M.]; *Oil of sassafras*, two cubic centimeters, (2 Cc.) [32.5 M.]. (3) *Compound spirit of orange* (U. S. P.), one and one-half cubic centimeters (1.5 Cc.) [24 M.]. (4) *Oil of gaultheria*, two cubic centimeters (2 Cc.) [32.5 M.]; *oil of bitter almond*, one-fourth cubic centimeter (0.25 Cc.) [4 M.]; *oil of coriander*, one-fourth cubic centimeter (0.25 Cc.) [4 M.]. (5) *Oil of gaultheria*, one and one-half cubic centimeters (1.5 Cc.) [24 M.]; *oil of sassafras*, one and one-half cubic centimeters (1.5 Cc.) [24 M.]; *oil of bitter almond*, one-fourth cubic centimeter (0.25 Cc.) [4 M.]. (6) *Oil of gaultheria*, two and one-half cubic centimeters (2.5 Cc.) [41 M.]; *oil of bitter almond*, two and one-half cubic centimeters (2.5 Cc.) [41 M.]. (7) *Oil of neroli*, one and one half cubic centimeters (1.5 Cc.) [24 M.]; *oil of bitter almond*, one and one-half cubic centimeters (1.5 Cc.) [24 M.]; *oil of cloves*, one-fourth cubic centimeter (0.25 Cc.) [4 M.].

C. Preservation.—"When an emulsion of cod-liver oil is to be kept for some time, its deterioration may be prevented or retarded by the addition of sixty-five cubic centimeters (65 Cc.) [2 fl̄z, 95 M] of alcohol in the place of the same quantity of water, when making one thousand cubic centimeters (1000 Cc.) [33 fl̄z, 391 M] of emulsion."

EMULSUM AMMONIACI (U. S. P.)—EMULSION OF AMMONIAC.

SYNONYMS: *Mistura ammoniaci* (Pharm., 1880), *Lac ammoniaci*, *Emulsio ammoniaci*, *Milk of ammoniac*, *Ammoniacum mixture*.

Preparation.—"Ammoniac, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄z, 391 M]. Rub the ammoniac in a warmed mortar, with nine hundred cubic centimeters (900 Cc.) [30 fl̄z, 208 M] of water, at first very gradually added, until a uniform emulsion results. Then strain the mixture into a graduated vessel, and wash the mortar and strainer with enough water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl̄z, 391 M]"—(U. S. P.).

Description and Dosage.—A milk-like preparation, hence its name, *milk of ammoniac*, the appearance being due to the suspended resinous and oleaginous bodies, the first of which largely precipitates upon standing. Acids slightly curdle the mixture. Uses, those of ammoniac. Dose, 1 to 4 fluid drachms.

EMULSUM AMYGDALÆ (U. S. P.)—EMULSION OF ALMOND.

SYNONYMS: *Mistura amygdalæ* (Pharm., 1880), *Milk of almond*, *Almond mixture*, *Emulsio simplex*, *Simple emulsion*, *Emulsio amygdalæ*, *Emulsio amygdalarum*.

Preparation.—"Sweet almond, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; acacia, in fine powder, ten grammes (10 Gm.) [15 grs.]; sugar, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄z, 391 M]. Having blanched the almonds, add the acacia and sugar, and beat them in a mortar until they are thoroughly mixed. Then rub the mass with nine hundred cubic centimeters (900 Cc.) [30 fl̄z, 208 M] of water, at first very gradually added, until a uniform mixture results. Strain this into a graduated vessel, and wash the mortar and strainer with enough water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl̄z, 391 M]. Mix the whole thoroughly"—(U. S. P.).

Acacia is present in this formula ostensibly for its mechanical action, but it is wholly unnecessary, as it enables no more oil to be suspended, nor does it add to the keeping properties of the emulsion. Care should be exercised to select almonds that have not become rancid. Emulsion of almond is not permanent, the oleaginous portion separating to form a creamy upper stratum. In warm weather it readily sours. Alcohol and heat cause the separation of the ingredients, while acids coagulate the albuminous matter present, thus favoring separation. Emulsion of almond has the appearance of milk, and possesses a bland taste.

Action, Medical Uses, and Dosage.—This agent is demulcent and nutritive. It may be freely used in *catarrhal disorders*, *irritated urinary passages*, and *dysentery*. It forms an agreeable vehicle for medicines not acid in character. Dose, 2 to 8 fluid ounces.

EMULSUM ASAFETIDÆ (U. S. P.)—EMULSION OF ASAFETIDA.

SYNONYMS: *Mistura asafetidæ* (Pharm., 1880), *Milk of asafetida*, *Asafetida mixture*, *Lac asafetidæ*.

Preparation.—"Asafetida, in selected tears, forty grammes (40 Gm.) [1 oz. av., 180 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄z, 391 M]. Rub the asafetida, in a warmed mortar, with nine hundred cubic centimeters (900 Cc.) [30 fl̄z, 208 M] of water, at first very gradually added, until a uniform emulsion results. Then strain the mixture into a graduated vessel, and wash the mortar and strainer with enough water to make the product measure one thousand cubic centimeters (1000 Cc.) [33 fl̄z, 391 M].

Mix the whole thoroughly"—(*U. S. P.*). About 18½ grains of asafetida to the ounce of water are contained in this emulsion.

Action, Medical Uses, and Dosage.—This is the best preparation of asafetida. It is also used as an enema. Dose, ¼ to 1 fluid ounce.

EMULSUM CHLOROFORMI (*U. S. P.*)—EMULSION OF CHLOROFORM.

SYNONYMS: *Mistura chloroformi* (*Pharm.*, 1880), *Chloroform mixture*, *Emulsio chloroformi*.

Preparation.—"Chloroform, forty cubic centimeters (40 Cc.) [1 fl̄, 169 M]; expressed oil of almond, sixty cubic centimeters (60 Cc.) [2 fl̄, 14 M]; tragacanth, in very fine powder, fifteen grammes (15 Gm.) [231 grs.]; water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Introduces the tragacanth into a perfectly dry bottle of sufficient capacity, add the chloroform, and shake the bottle thoroughly, so that every part of the surface may become wetted. Then add about two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 M] of water, and incorporate it by vigorous shaking. Next add the expressed oil of almond, in several portions, shaking after each addition, and when the oil has been thoroughly emulsified, add enough water in divided portions, shaking after each addition, until the product measures one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]"—(*U. S. P.*).

This preparation is preserved by the chloroform, and does not separate on standing. It contains 4 per cent of chloroform, differing in this respect from the formula of 1880, which contained 5 per cent, and in addition camphor; yolk of egg being the emulsifying medium.

Action, Medical Uses, and Dosage.—This is a convenient and stable preparation of chloroform, and may be used in the various forms of *colic*, as *uterine*, *flatulent*, *renal*, and *biliary colic*, and in *gastralgia*, *hysteria*, and other *nervous derangements*. Dose, ¼ to 1 fluid ounce.

Related Preparation.—*MISTURA CHLOROFORMI* (*U. S. P.*, 1880). "Purified chloroform 8 parts, camphor 2 parts, fresh yolk of egg 10 parts, water 80 parts; to make 100 parts. Rub the yolk of egg in a mortar, first by itself, then with the camphor, previously dissolved in the chloroform, and lastly with the water, gradually added, so as to make a uniform mixture"—(*U. S. P.*, 1880).

EMULSIO OLEI MORRHUÆ (*N. F.*)—EMULSION OF COD-LIVER OIL.

Preparation.—*Formulary number*, 124: "Cod-liver oil, four hundred and sixty-four grammes (464 Gm.) [1 lb. av., 160 grs.]; acacia, in fine powder, one hundred and sixteen grammes (116 Gm.) [4 oz. av., 40 grs.]; syrup of tolu (*U. S. P.*), one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M]; flavoring (*F.* 123, B), water, of each a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Triturate the oil and acacia together in a mortar. Carefully weigh out one hundred and seventy-four grammes (174 Gm.) [6 ozs. av., 60 grs.] of water, and add it *at once* to the mixture of oil and acacia, triturating briskly until a thick, creamy emulsion is produced. To this add the desired flavoring, the syrup of tolu, and enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M] of the finished emulsion"—(*Nat. Form.*).

Alternative Formulas.—(For flavoring see Formula 123, B. *Emulsiones*). Emulsion of cod-liver oil may also be prepared by any other method capable of emulsifying oil, the following formulas being given as examples:

IRISH MOSS EMULSION OF COD-LIVER OIL.—"Cod-liver oil, five hundred cubic centimeters (500 Cc.) [16 fl̄, 435 M]; mucilage of Irish moss (*F.* 275), three hundred and twenty-five cubic centimeters (325 Cc.) [10 fl̄, 475 M]; syrup of tolu (*U. S. P.*), one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M]; flavoring (*F.* 123, B), water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Pour the mucilage of Irish moss into a suitable bottle, add the cod-liver oil in divided portions, shaking well after each addition, and when a perfect emulsion is formed, add the syrup of tolu and flavoring, and lastly, enough

water to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Finally, mix the whole thoroughly together"—(*Nat. Form.*).

GLYCERIN EMULSION OF COD-LIVER OIL.—"Cod-liver oil, five hundred cubic centimeters (500 Cc.) [16 fl̄, 435 M]; glycerite of yolk of egg (*U. S. P.*), one hundred and seventy-five cubic centimeters (175 Cc.) [5 fl̄, 440 M]; syrup of tolu (*U. S. P.*), one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M]; flavoring (F. 123, B.), water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Triturate the glycerite of yolk of egg (glycerin) in a mortar with the oil, added in small portions at a time, and thoroughly incorporate each portion before adding the next. Then, continuing the trituration, gradually add the syrup of tolu, and flavoring. Finally, add enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M], and mix the whole thoroughly together"—(*Nat. Form.*).

QUILLAJA EMULSION OF COD-LIVER OIL.—"Cod-liver oil, five hundred cubic centimeters (500 Cc.) [16 fl̄, 435 M]; tincture of quillaja (*U. S. P.*), sixty-five cubic centimeters (65 Cc.) [2 fl̄, 394 M]; syrup of tolu (*U. S. P.*), one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M]; flavoring (F. 123, B.), water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Pour the tincture into a suitable bottle, then add the cod-liver oil in portions of about one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl̄, 109 M] each, and shake after each addition until a perfect emulsion results. Next add the syrup of tolu, and the flavoring, and lastly, enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Finally mix the whole thoroughly together. An 85 per cent emulsion of cod-liver oil may be prepared by mixing in the manner just prescribed: Cod-liver oil, eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 M]; tincture of quillaja (*U. S. P.*), one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M]; flavoring (F. 123, B.), syrup of tolu (*U. S. P.*), of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. *Note.*—Emulsion of cod-liver oil made with quillaja should not be dispensed without the direction or consent of the prescriber"—(*Nat. Form.*).

EMULSIO OLEI MORRHUÆ CUM HYPOPHOSPHITE (N. F.)—

EMULSION OF COD-LIVER OIL WITH HYPOPHOSPHITE.

Preparation.—*Formulary number, 129:* "Cod-liver oil, four hundred and sixty-four grammes (464 Gm.) [1 lb. av., 160 grs.]; acacia, in fine powder, one hundred and sixteen grammes (116 Gm.) [4 ozs. av., 40 grs.]; any soluble hypophosphite, seventeen and one-half grammes (17.5 Gm.) [270 grs.]; syrup of tolu (*U. S. P.*), one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M]; flavoring (F. 123, B.), water, of each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Emulsify the oil with the acacia and one hundred and seventy-four grammes (174 Gm.) [6 ozs. av., 60 grs.] of water, as directed under *Emulsio Olei Morrhue* (F. 124), and add the flavoring. Then dissolve the hypophosphite in sufficient water, mix this solution with the syrup, and add the mixture gradually to the emulsified oil. Lastly, add enough water to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M], and mix the whole thoroughly. *Note.*—If several hypophosphites are required, equal parts of them may be used, amounting altogether to seventeen and one-half grammes (17.5 Gm.) [270 grs.] for the above formula. Varying quantities, larger or smaller than the above, may of course, be used upon prescription"—(*Nat. Form.*).

EMULSIO OLEI RICINI (N. F.)—EMULSION OF CASTOR OIL.

Preparation.—*Formulary number, 131:* "Castor oil, thirty-two grammes (32 Gm.) [1 oz. av., 56 grs.]; acacia, in fine powder, eight grammes (8 Gm.) [123 grs.]; tincture of vanilla (*U. S. P.*), two and one-half cubic centimeters (2.5 Cc.) [41 M]; syrup (*U. S. P.*), twenty cubic centimeters (20 Cc.) [325 M]; water, a sufficient quantity to make one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M]. Carefully weigh the castor oil and the acacia into a mortar, triturate until well mixed; carefully weigh out twelve grammes (12 Gm.) [185 grs.] of water, and add at once to the mixture of oil and acacia, triturating briskly until a thick, creamy emulsion is produced. To this add gradually, with stirring, a mixture of the syrup and tincture with a portion of the remaining water, and finally enough water to make one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M]. The emulsion contains about one-third ($\frac{1}{3}$) of its volume of castor oil. The flavoring may be varied to suit prescription. It should be freshly prepared as required"—(*Nat. Form.*).

EMULSIO OLEI TEREBINTHINÆ (N. F.)—EMULSION OF OIL OF TURPENTINE.

Preparation.—*Formulary number, 132:* "Oil of turpentine, twelve and one-half cubic centimeters (12.5 Cc.) [203 M]; acacia, in fine powder, two grammes (2 Gm.) [31 grs.]; yolk of egg, fifteen cubic centimeters (15 Cc.) [243 M]; aromatic elixir (*U. S. P.*), fifteen cubic centimeters (15 Cc.) [243 M]; cinnamon water (*U. S. P.*), a sufficient quantity to make one hundred cubic centimeters (100 Cc.) [3 fl. 3, 183 M]. Triturate the acacia with the yolk of egg, then add the oil of turpentine very slowly, continuing the trituration, and finally add the aromatic elixir, and enough cinnamon water to make one hundred cubic centimeters (100 Cc.) [3 fl. 3, 183 M], in the same manner"—(*Nat. Form.*).

Emulsion of oil of turpentine, or any volatile oil, may also be prepared according to the following general formula: "Volatile oil, twelve and one-half cubic centimeters (12.5 Cc.) [203 M]; acacia, in fine powder, six grammes (6 Gm.) [93 grs.]; syrup, twenty-five cubic centimeters (25 Cc.) [406 M]; water, a sufficient quantity to make one hundred cubic centimeters (100 Cc.) [3 fl. 3, 183 M]. Pour the volatile oil into a dry bottle, and, having corked the latter, agitate it so that the inner surface may be completely wetted by the oil. Then add the acacia, and shake again. Finally add the syrup, and enough water to make one hundred cubic centimeters (100 Cc.) [3 fl. 3, 183 M], and mix thoroughly. *Note.*—If this general formula is applied to emulsion of oil of turpentine, and a product similar to that obtained by the first formula is desired, the syrup should be replaced by aromatic elixir, and the water by cinnamon water. If a so-called "emulsion" of a volatile oil is to be made more permanent, this may be accomplished by incorporating with it a small portion of some bland fixed oil, such as expressed oil of almond. Usually, 1 volume of the fixed oil will be sufficient for 2 volumes of the volatile oil. In this case the mixture should be made in a mortar, by trituration, and under observation of the rule laid down in general formula for emulsions (F. 123)"—(*Nat. Form.*).

ENEMATA.—OLYSTERS.

SYNONYMS: *Injections, Enemas, Lavements, Clysteria, Clysmata.*

Injections are medicinal agents in the form of infusion, decoction, or mixture, designed to be passed into the rectum, vagina, urethra, bladder, etc. Sometimes pulverized ingredients are added to those intended for the rectum. They are usually thrown into the rectum to remove constipation, to allay inflammation of the lower intestines, to remove ascarides, to stimulate or nourish the system, to produce an influence upon distant organs by sympathetic action, as to occasion emesis, perspiration, uterine action, etc., and as a revulsive. When, from any cause whatever, medicines or liquid food can not be administered by mouth, they may be used in the form of a rectal injection, in about double the quantity required when taken into the stomach; though some care is necessary in proportioning the dose of powerful medicines. When an evacuation of the bowels is designed, as in *bilious colic, apoplexy, convulsions, constipation, etc.*, the quantity of fluid should be large, 1 or 2 pints for an adult, repeating it every 10, 20, or 30 minutes, until the object is effected. Children will require reduced amounts, according to their ages and susceptibilities. When it is desired to make an impression upon distant or neighboring parts, or upon the rectum itself, or to produce a constitutional influence, the injection should be given in as small an amount of fluid as is consistent with its activity or character, and should be held within the rectum as long as possible; and if the patient can not retain it, a warm compress of linen or muslin may be pressed upon the anus with a moderate degree of firmness, by the nurse, which will prevent the enema from being immediately evacuated.

Injections into the vagina are intended to aid in restoring the normal condition of its walls, to assist in the cure of *excoriation or ulceration of the cervix*, to remove *vaginal leucorrhœa*, to produce a sedative influence upon the uterus, to induce premature delivery, etc. Uterine injections are designed to remove a low grade of inflammation of its mucous lining membrane, to cure ulceration in the canal of the cervix, to stimulate the organ to activity, etc. Urethral injections are to relieve inflammation of the urethra or bladder, to check chronic discharges from the urethra, heal ulceration of the bladder, stimulate the mucous lining membrane of the urethra,

and the prostate gland, etc. Injections into other parts are usually for the purpose either of removing foreign or unhealthy matters, allaying inflammation, stimulating the parts to increased action. Very salutary effects are frequently obtained in this way, better than it is possible under certain conditions to cure by administration of remedies by mouth. Many ingenious instruments are contrived for the administration of injections.

Injections are a valuable mode of treatment in many diseases; indeed, affections can not be readily nor permanently cured without them. They are found especially beneficial in *bilious colic*, in *bilious, typhus, yellow*, and other forms of fever, in *dysentery* and *diarrhœa*, etc. In infants, life has often been preserved by their timely application, and the pains and dangers of the parturient woman have frequently been very materially lessened by their use. And notwithstanding their value and importance, there are hundreds of families, especially in country places, who do not supply themselves with the instrument necessary for their administration, but who depend entirely upon the physician or perhaps a neighbor, for the use of a syringe. This is a very reprehensible omission, and, although not exactly within the province of this work, yet, from the evil results which I have seen depending upon a negligence of this character, I can not refrain from making a few brief advisory remarks. Every individual, and more especially every family, is liable to sickness which may require the use of a syringe, and to depend upon the physician for its supply is certainly bad policy, for very few, especially those practicing in the country, furnish themselves with a quantity sufficient to meet the demands of their families under their professional care; besides, very few physicians carry an article of this kind, and, in some diseases, the delay occasioned by sending for it may be death to the patient. No doubt, an immense number of patients, more particularly among those residing in the country, die yearly, solely from the want of an instrument with which to administer an injection. It is, therefore, a matter of duty with the practitioner, both to himself and to his patients, to strongly impress these facts upon those who patronize him professionally, and to urge them by all means to make the necessary provisions. A rubber or glass syringe, capable of holding a pint, and a smaller one of 3 or 4 fluid ounces, a rubber bulb and tube syringe, or a fountain syringe, should be found in the possession of every family, as these can be adapted to meet any emergency required in their use.

Injections are emollient, stimulant, anodyne, purgative, antispasmodic, and are most generally prescribed by the physician to suit the emergency of the case, without regard to official directions. For purposes of nutrition, as well as to reduce inflammation of the lower intestines, infusions of starch, of elm bark, flaxseed, and of cornmeal, are usually injected into the rectum, with a portion of laudanum added when inflammation is present; and in cases where the patient rejects all food and medicine, and when this condition is accompanied with delirium, a proper quantity of wine, brandy, or some similar stimulant, may be added to the nutrient clyster, and repeated as often as the circumstances require. The following enemata are among the agents of this class in more common use.

ENEMA ALOES, *Enema of aloes*.—Mix and rub together 40 grains of aloes, 15 grains of sodium carbonate, and 10 fluid ounces of mucilage of starch. This accords with the British Pharmacopœia. Uses same as for *Enema Aloes Composita*, which see.

ENEMA ALOES COMPOSITA, *Compound enema of aloes*, *Compound clyster of aloes*.—Take 40 grains, carbonate of potassium 15 grains, tincture of *asafoetida* 3 fluid drachms, infusion of boneset $\frac{1}{2}$ pint. Mix and rub them together. This is a stimulant, cathartic, and venous clyster, and may be used with advantage for the removal of *ascarides* from the rectum, in constipation, especially among females laboring under *amenorrhœa* (J. King). For the purpose of inducing catharsis large amounts should be used; for the destruction of *ascarides* to stimulate local parts, small quantities are preferable.

ENEMA CATHARTICUM, *Cathartic enema*, *Cathartic clyster*.—Take of common table salt 1 ounce, olive or castor oil 1 fluid ounce, molasses 2 fluid ounces, warm water 2 pints, together. This is a very common laxative clyster, the ingredients of which are generally procured readily in every family. The above quantity is intended for an adult; it may be given at once, or be divided into 2 equal parts, to be used within 10 or 15 minutes of each other. It is generally employed in cases of constipation, or where a speedy evacuation of the bowels is desired. An injection is sometimes used for the above purposes, and in *diarrhœa* and dysentery, and, indeed, in almost every case where an enema is indicated, composed as follows:

sweet milk $\frac{1}{2}$ pint, infusion of elm bark $\frac{1}{2}$ pint, olive oil 2 fluid ounces, molasses 4 fluid ounces, bicarbonate of potassium $\frac{1}{2}$ troy ounce. Mix. When there are pains and gripings in the lower intestines, laudanum $\frac{1}{2}$ fluid drachm may be added to each injection (Beach's *American Practice*).

ENEMA LOBELIÆ COMPOSITA, *Compound enema of lobelia*, *Compound clyster of lobelia*, *Antispasmodic clyster*.—Take of water $\frac{1}{2}$ fluid ounce, compound tincture of lobelia and capsicum $\frac{1}{2}$ fluid drachm. Mix together. This is a relaxant and antispasmodic clyster, and is used in cases of *tetanus*, *convulsions*, *rigidity of the os uteri*, and whenever its peculiar actions are indicated. The proportions, as given in the above formula are adapted to an infant from several weeks to a year old, laboring under an attack of convulsions; for adults, $\frac{1}{2}$ fluid ounce or even more of the tincture, may be added to a sufficient quantity of water, and so in proportion (J. King).

ENEMA MAGNESII SULPHATIS, *Enema of magnesium sulphate*, *Enema catharticum*.—Dissolve 1 ounce (av.) of magnesium sulphate in 15 fluid ounces of mucilage of starch, add 1 fluid ounce of olive oil, and mix. This accords with the *Br. Pharm.* This enema is of value in *cerebral congestion* where a derivative effect is desired and as an evacuant in *obstinate constipation*. Large amounts should be used. A simple solution of magnesium sulphate without the other ingredients would be just as effective.

ENEMA OPII, *Enema of opium*, *Clyster of opium*, *Enema sedativum*, *Enema anodynum*.—Take of decoction of starch, or infusion of elm bark 1 fluid ounce, tincture of opium 20 minims. Mix them. The *Br. Pharm.* directs tincture of opium $\frac{1}{2}$ fluid ounce, and mucilage of starch 2 fluid ounces. This clyster is useful in *irritation or inflammation of the bladder, uterus, or prostate gland*, in *obstinate emesis*, in the passage of *renal calculi*, in *nephritis*, in *dysentery*, and in *painful affections of the large intestines*. It may sometimes be necessary to double or treble the quantity of tincture of opium named in the formula. It should be retained in the rectum as long as possible, and may be repeated every 1, 2, or 3 hours, and in severe cases even oftener, according to the urgency of the symptoms. If frequently employed it will produce the constitutional effects of the opium.

ENEMA TABACI, *Enema of tobacco*.—Infuse in a closed vessel for 30 minutes, 20 grains of leaf tobacco in 8 fluid ounces of boiling water (*Br. Pharm.*, 1867). This enema is designed to produce nausea and consequent muscular relaxation in cases of *strangulated hernia, ileus, fecal accumulations*, and other *bowel obstructions*, to induce alvine evacuations. It must be carefully used. It has been used in *tetanus*, and for the destruction of *ascarides*. Not more than $\frac{1}{2}$ ounce of this preparation should be employed at one injection.

ENEMA TEREBINTHINÆ, *Enema of turpentine*.—Mix 1 fluid ounce of oil of turpentine with 15 fluid ounces of mucilage of starch. This accords with the *Br. Pharm.* Of value in *tympanitic distension of the intestines* when confined to the colon. Also used to destroy *ascarides*, and in *hysteria and amenorrhœa*, and is said to give marked relief from the pain produced by the presence of *vesical calculus*.

ENEMA TEREBINTHINÆ COMPOSITA, *Compound enema of turpentine*, *Compound clyster of turpentine*.—Take of castor oil $\frac{1}{2}$ fluid ounce, oil of turpentine 2 fluid drachms, camphorated tincture of opium 1 fluid drachm. Mix together. This injection is principally employed in *flatulency*, and *tympanitic distension of the abdomen*, especially during an attack of *peritonitis*. It may be repeated 2, 3, or 4 times a day. It may likewise be used in *ascarides*, *obstinate constipation*, and *amenorrhœa*.

EPIGÆA.—TRAILING ARBUTUS.

The leaves of *Epigæa repens*, Linné.

Nat. Ord.—Ericacææ.

COMMON NAMES: *Trailing arbutus*, *Winter-pink*, *Gravel-weed*, *Gravel plant*, *Mountain-pink*, *Ground laurel*, *May-flower*.

Botanical Source.—This is a small trailing plant, indigenous, with woody stems from 6 to 20 inches long, and covered with a hairy pubescence in all its parts. Its leaves are evergreen, alternate, cordate-ovate, entire, 2 or $2\frac{1}{2}$ inches long, by $1\frac{1}{2}$ wide, roundish at the end, abruptly tipped with a very short point, and borne on slender petioles. The flowers, which are very fragrant and white, or tinged with various shades of red, are disposed in small axillary clusters on short stalks. The corolla is hypocrateriform, tube cylindrical, longer than the calyx, hairy within; limb 5-parted and spreading. The calyx is green, 5-parted, with 3 large bracts at base; stamens 10, with filiform filaments; anthers oblong, awnless, dehiscent by two longitudinal openings. The capsule or pod is depressed, globular, 5-lobed, 5-celled, and many-seeded (W.—G.). According to Mr. Thomas Meehan, this is a dioecious plant.

History.—This shrubby little plant grows in sandy woods, sometimes in rocky soil in the shade of pines, and is found from Newfoundland to Northwest Territory and Michigan, and south to Kentucky and Florida. Its flowers exhale a rich, spicy fragrance, and appear from March to May. It is much sought in early spring, and admired by flower lovers for its modest beauty and fragrance. Cattle that chew this herb are said to be seriously affected by it. The leaves

which have an astringent, bitterish taste, are the medicinal parts, and yield properties to water or spirits.

Chemical Composition.—Trailing arbutus contains tannin, as shown by Jefferson Oxley (*Amer. Jour. Pharm.*, 1872, p. 253). He also observed a body

Fig. 103.

Epigaea repens

some of the test reactions for gallic acid, but differed from the latter in not yielding pyrogallol by dry distillation. Mr. Oxley also found formic acid and the following principles, which also occur in *Uva ursi*, which see: glucosid *arbutin* ($C_{12}H_{20}O_7$), *urson* ($C_{22}H_{34}O_{12}$), and the bitter glucosid *ericolin* ($C_{22}H_{34}O_{12}$) or, according to others ($C_{22}H_{36}O_{12}$). Grape sugar, gum, and coloring matter are found in addition to the constituents mentioned.

Action, Medical Uses, and Dosage.—Trailing arbutus specifically influences the urinary organs. It is retic and astringent. This is a very valuable American remedy, and is highly beneficial in *lithic acid gravel*; all diseases of the urinary organs attended with irritation; it is superior to *uva ursi*, or foreign buchu, and where these have failed in producing benefit, this has succeeded. It may be used as a substitute for *uva ursi*. It renders urine less irritating, and will be found of value in *vesical tenesmus*, *dysuria*, and *strangury*. A discharge of bloody muco-pus is an indication for its exhibition. Fluid extract and specific epigaea are elegant preparations for all urinary difficulties. It enters into a very

preparation termed *Diuretic compound*, which see under the head of *Infusions*. It has been occasionally used with advantage in *diarrhœa*, and *bowel complaint* in children. The infusion of the leaves may be drunk freely. Dose of specific 10 to 30 drops in water every 2 to 6 hours; fluid extract, 10 to 40 drops.

Specific Indications and Uses.—Uric acid deposits; irritable vesical membrane; voiding of urine containing blood or muco-pus; debilitated and relaxed bladder.

EPIPHEGUS.—BEECH DROPS.

The whole plant of *Epiphegus virginiana*, Barton (*Epiphegus americanus*, Nutt.); all; *Orobanche virginiana*, Linné).

Nat. Ord.—Orobanchaceæ.

COMMON NAMES: *Beech-drops*, *Cancer-root*.

ILLUSTRATION: Meehan's *Native Flowers and Ferns*, Vol. II, p. 93.

Botanical Source.—This plant is the *Epiphegus americanus* of Nuttall, and *Orobanche virginiana* of Linné, and is also known by the name of *Cancer-root*. It is a parasitic growth, with a smooth, fleshy, leafless stem, about 1 or 1½ feet high, with slender and irregular branches given off along its whole length. The root is scaly, tuberous, and covered with stiff, short, and brittle radicles. Instead of leaves it has only a few scattered, inconspicuous, ovate scales, one at the base of each branch, of a yellowish or purplish color. The flowers are alternate, scattered on each branch, subsessile, the lower perfect and fertile, the upper usually imperfect and abortive. Calyx short and 5-toothed. Corolla of the perfect flowers 2-lipped; upper lip emarginate, lower 3-toothed; of the imperfect, slightly 4-toothed, deciduous, 6 to 8 lines long, curved, whitish, and purple; upper lip or lip broadest, notched at the apex, arched not longer than the others. The stamens are as long as the corolla; the filament smooth; the anthers 2-lobed, acute at the base; valveless and dehiscent in the middle. Stigma capitate, somewhat emarginate. Capsule gibbous, truncate, oblique, 1-celled, compressed, bilobed at the apex, with 2 approximate placenta on each. The seeds are numerous, straw-colored, shining (L.—W.—G.).

History and Description.—This plant is found throughout North America, parasitic upon the roots of beech trees, and flowering in August and September. The whole plant has a dull-red color, without any verdure. It has a disagreeable astringent, and amarous taste, much lessened by desiccation. It yields its virtues

to water. There are several other species of this genus, which are parasitic, and which possess analogous properties, as the *Aphyllon uniflorum*, Gray (*Orobanche uniflora*, Linné), or *One-flowered* or *Naked broomrape*, and the *Conopholis americana*, Wallroth (*Orobanche americana*, Linné), or *American broomrape*, *Squaw-root*, or *Cancer-root*.

Action, Medical Uses, and Dosage.—An astringent. Used with benefit in hemorrhages of the bowels and uterus, and in diarrhœa. Said to cure cancer, but it possesses no property of the kind. In *erysipelas*, a decoction drank freely, and the parts bathed with it, has effected many cures. As a local application, the decoction or poultice will arrest the tendency of wounds or ulcers to gangrene; a poultice of equal parts of poke, white oak, and beech-drops is very useful in herpetic affections. Also useful as a topical application to obstinate ulcers, aphthous ulcerations, leucorrhœa, gleet, etc. The homœopaths extol it in headaches brought on by fatigue and journeys. This plant seems to exert an influence upon the capillary system, somewhat similar to that produced by the tincture of chloride of iron. Dose of the powder, from 10 to 15 grains. The decoction may be drank freely.

EPILOBIUM.—WILLOW HERB.

The leaves and root of *Epilobium angustifolium*, Linné, and *Epilobium palustre*, Linné.

Nat. Ord.—Onagraceæ.

COMMON NAMES: I. *Epilobium angustifolium*—Willow herb, Great willow herb, Rose-bay, Wickup. II. *Epilobium palustre*—Marsh epilobium, Wickop, Swamp willow herb.

Botanical Source.—*Epilobium angustifolium*. This plant, sometimes known as *Rose-bay*, is the *Epilobium spicatum* of Lamarck; it is a perennial, indigenous plant, with a simple, erect stem from 4 to 6 feet in height. The leaves are scattered, lanceolate, sessile, smooth, subentire, with a marginal pellucid vein, from 2 to 5 inches in length, and one-fourth as wide. The flowers are large, numerous, very showy, pink-purple, and in a long terminal spike or raceme. The corolla has 4 deep, lilac-purple petals, clawed, and widely spreading. The calyx-tube is not prolonged beyond the ovary; the limb is 4-cleft, 4-parted, and deciduous. Stamens 8, and as well as the style, turned to one side. The stigma has 4 linear, long, revolute lobes. The ovary and capsule are long, linear, 4-cornered, 4-celled, and 4-valved; and the seeds numerous with a tuft of long hairs (W.—G.). *Epilobium palustre* has a terete, branching, somewhat hirsute stem, growing from 1 to 2 feet in height, sessile, lanceolate, or linear, entire or subdenticulate, smooth leaves, attenuate at base, rather acute, alternate; lower ones opposite, and from 1 to 3 inches long, and one-third as wide. The flowers are small, numerous, axillary, rose-colored, or purplish, and in the narrow-leaved variety (var. *albidum*), white. The petals are small, obcordate, twice longer than the calyx; style included; stigma clavate; capsules 1 or 2 inches long, not over $\frac{1}{8}$ of an inch in diameter, borne on short pedicels, and pubescent.

Fig. 104.

Epilobium angustifolium.

History and Chemical Composition.—*Epilobium angustifolium*, when in bloom is a conspicuous feature of our landscape, from July to September. It grows plentifully from Pennsylvania northward, and to some extent in the mountainous districts of North Carolina, and from thence westward and northward. Like *fireweed* (*Erechtites hieracifolia*), it may be found growing in one place one year, and the next year may disappear therefrom, and reappear in a new situation several miles distant. In some localities, however, it is almost constant, coming year after year in the same spot. This plant is known by various names, the best known of which are *willow herb*, *wickup*, and *rose-bay*. In contradistinction to other species known likewise as *wickup* and *willow herb*, it is called *great willow herb*. Willow herb is a perennial, growing along waysides, railroads, along the fences of pasture lands, as well as in new ground recently cleared by burning. Mr. C. J. Biddle found the root of *Epilobium angustifolium* to contain mucilage,

tannin, starch, sugar, resin, and a crystalline calcium salt (*Amer. Jour. Pharm.*, 1877). Several species of epilobium are indigenous, *Epilobium palustre* or swamp epilobium being valued as possessing similar medicinal virtues to the plant in question. The roots of epilobium possess some activity, but the leaves are preferred. They yield their virtues to water or alcohol.

Epilobium palustre, or *Swamp willow herb*, grows in swamps and marshes from Pennsylvania to Arctic America, and westward to Oregon.

Action, Medical Uses, and Dosage.—Epilobium has never attained a place in the front rank as a medicine. This is often the case with drugs that have not decided poisonous properties, or with such drugs as have not yielded to the chemist an active principle. That it has not attained prominence as a remedy is not the fault of the plant, for in certain cases of *summer bowel troubles* it is without an equal. The infusion is probably the best form of administration, though alcoholic preparations are not without remedial activity. Specific epilobium is a reliable preparation. The infusion is not unpleasant, its taste being somewhat like that of tea. Epilobium is tonic, astringent, demulcent and emollient. The uses given for it are many, but we would particularly allude to its value in *summer bowel complaints*. It has a deserved reputation in *chronic diarrhœa*, and it has been known to give better service than other remedies in diarrhœas following, or dependent in the first place on "*camp or army diarrhœa*." The infusion should be freely used. Several cases of diarrhœa of a watery character, due to change of drinking water, have been promptly checked by the infusion or the tincture. Certain forms of *cholera infantum*, especially with greenish discharges of undigested aliment, have been controlled by this agent in domestic practice, where the ordinary remedies prescribed by the physician failed to have any beneficial effect. It is prominent as a remedy for *mucro-enteritis*. Administered in very small doses it has proven effective in a large number of cases of *typhoid dysentery*. With Prof. Scudder, infusion of epilobium was a favorite remedy to correct and restrain the diarrhœa of *typhoid or enteric fever*. In this particular condition others attest its efficacy. It is a good remedy in *intestinal irritation*, as a wrong of intestinal digestion. It is indicated here by the pinched features, emaciation, and the slick, contracted tongue, the papillæ being somewhat effaced. It is further indicated in bowel troubles by impairment of digestion with uneasy sensations in the abdomen, amounting to pain, accompanied by diarrhœa and having the above symptoms of bowel irritation.

An infusion of the leaves will be found beneficial in *leucorrhœa*, *menorrhagia*, and *uterine hemorrhage*; and forms an excellent local application for *ophthalmia*, *ulcerations of the mouth and throat*, and *leucorrhœa*. The leaves in poultice are a valuable remedy for foul and indolent ulcers. Dose of the infusion, sweetened if desired, from 2 to 4 fluid ounces, 5 or 6 times a day, or smaller doses may be repeated every 10, 20, 30 or 60 minutes as required.

Epilobium palustre, marsh epilobium, wickop, or swamp willow herb, is said to be a valuable article in *colic* and in *irritable conditions of the intestines*; in severe *dysentery*, *camp diarrhœa*, formerly known as "*Mexican diarrhœa*," and *cramp of the stomach*. In fact it acts similarly to willow herb. It has proved quite successful in some very severe cases of colic and dysentery, even after the failure of other agents. Prof. J. M. Scudder extols this plant very highly in the above diseases, and also in *ulceration of the bowels* attending *typhoid fever*, as it quiets irritation, gradually checks diarrhœa, and relieves tenderness and tympanitis. He prescribes a tablespoonful every hour of an infusion made by infusing an ounce of the herb in $\frac{1}{2}$ pint of boiling water. The dose of specific epilobium ranges from 10 to 60 drops. The infusion may be freely used.

Specific Indications and Uses.—Prof. Scudder gives the following specific indications: "Diarrhœa, with colicky pain; feculent discharges with tenesmus; diarrhœa, with contracted abdomen; chronic diarrhœa, with harsh, dirty, contracted skin." Diarrhœa of typhoid fever; typhoid dysentery.

Related Species.—*Epilobium hirsutum*, Linné; *Great hairy willow herb*, *Fiddle-grass*, *Cod-lins-and-cream*. Adventive from Europe, and found in waste places in eastern New England, Ontario, central New York, and in the ballast near seaports (Britton and Brown). Dr. Oliver (see *Amer. Hom.*, 1897, p. 442) reports the case of a three-year-old boy, poisoned by eating *Epilobium hirsutum*. The symptoms were profound coma and recurring epileptiform convulsions.

EQUISETUM.—SCOURING RUSH.

The plant *Equisetum hyemale*, Linné.

Nat. Ord.—Equisetaceæ.

COMMON NAMES: *Scouring rush*, *Horse-tail*, *Shave-grass*.

Botanical Source.—This is a perennial plant, with simple, stout, erect, jointed, and hollow stems, marked with from 14 to 26 longitudinal furrows, the ridges rough with 2 rows of minute tubercles, growing from 2 to 3 feet in height, each stem bearing a terminal, ovoid spike. Frequently 2 or more stems are united at the base from the same root. The sheaths are from 2 to 3 lines long, from an inch to an inch and a half apart, ashy-white, black at the base and summit, short, with subulate, black, awned, deciduous teeth, which leave a bluntly crenate margin. The fertile plants are mostly leafless. The fruit is placed under peltate polygons, being pileus-like bodies, arranged in whorls, forming a spike-like raceme, from 4 to 7 spiral filaments surround the spores, which resemble green globules, and which roll up closely around them when moist, and uncoil when dry (G.—W.).

History and Chemical Composition.—This plant is common to the northern and western parts of the United States, growing in wet grounds, on river banks, and borders of woods, and maturing in June and July. Together with other *Cryptogamia*, this species abounds in the fossil remains of coal measures, indicating that they were once of gigantic dimensions, and formed a large part of the original flora of our globe. Silica enters largely into the composition of these plants, on which account they have been used to scour, rough polish, etc.; 1.4 per cent of a brownish-green, semi-fluid fixed oil, easily saponifiable, was abstracted from this plant by F. J. Young, by means of petroleum benzin (*Amer. Jour. Pharm.*, 1886, p. 420). The plant left 18.2 per cent of ash, and proved to be free from tannin, alkaloid, or glucosid. Mucilage, sugar, and a soft, green resin were shown to be present. The *equisetic acid* of Braconnot was found by Regnault to be identical with *aconitic acid*. The whole plant is medicinal, and imparts its properties to water.

Action, Medical Uses, and Dosage.—Diuretic and astringent. An infusion (ʒij to aqua Oj) drank freely, has been found beneficial in *dropsy*, *suppression of urine*, *hematuria*, *gravel*, and *nephritic affections*; and has also been used with advantage in *gonorrhœa* and *gleet*. This drug has a specific action in *irritation of the bladder*, and in *dysuria* with tenesmic urging, in the *nocturnal urinal incontinence* of children, and in *urinal incontinence*, the effect of cystic irritation, it is a very serviceable remedy. The infusion or the decoction of the green stalks is preferred. The ashes of the plant are very valuable in *dyspepsia* connected with *obstinate acidity of the stomach*, and may be given alone, or combined with powdered rosin, or hydrochlorate of berberine, etc. Dose of the pulverized ashes from 3 to 10 grains, to be repeated 3 or 4 times daily. The fresh juice may be given in 1 or 2 ounce doses, administered in water. Specific *equisetum*, 5 to 60 drops.

Specific Indications and Uses.—Cystic irritation; nocturnal urinal incontinence; tenesmic urging to urinate; dropsy; renal calculi.

Related Species.—*Equisetum terigatum*, Braun, and *Equisetum robustum*, Braun, of the southern and western borders of our country, may be substituted for the above.

Equisetum arvense, Linné; *Common horse-tail*.—Canada to Kentucky and Virginia. This species puts forth its sterile stems after the appearance of the fertile ones. It has the medicinal uses of *Scouring rush*.

ERECTITES.—FIREWEED.

The entire plant and oil of *Erechtites hieracifolia*, Rafinesque (*Senecio hieracifolius*, Linné).

Nat. Ord.—Compositæ.

COMMON NAME: *Fireweed*.

ILLUSTRATION: Lloyd's *Drugs and Med. of N. A.*, Vol. II, Plate 38.

Botanical Source.—This plant is the *Senecio hieracifolius* of Linnæus. It has an annual herbaceous, grooved, thick, fleshy, branching, virgate panicle, and roughish stem, from 1 to 5 or even 8 feet high. The leaves are simple, alternate, large, lanceolate or oblong, acute, unequally and deeply toothed with acute indentures, sessile, and light-green; the upper ones often have an auricled clasping base. The flowers are greenish, or about the same hue as the plant, terminal, crowded, and destitute of rays. The involucre is smooth, large, tumid, and bristly at the base. The achenia are oblong and hairy (W.—G.).

Fig. 105.

Erchites hieracifolia.

History and Description.—This is an indigenous, rank weed, growing in fields throughout the United States, in moist woods, and in recent clearings, especially and abundantly in such as have been burned over, hence its vernacular name *Fireweed*. From the fact of its brittleness and consequent liability to be easily broken, it is seldom found where animals graze. It flowers from August to October, and resembles in appearance the sow-thistle (*Sonchus oleraceus*); the flowers somewhat resemble those of lettuce. The whole plant is medicinal, and yields its virtues to water or alcohol. It has a peculiar, aromatic, and somewhat fetid odor, very unpleasant to many persons, and a peculiar, slightly pungent, bitterish, rather disagreeable taste, with some astringency. The leaves, which are most generally employed, when dried are almost black, and by this characteristic, as well as by form, may be distinguished from those of *Erigeron canadense*, or *Erigeron annuum*, with which they are sometimes confused. The former plant is often erroneously called *Fireweed*. *Erechites* is often incorrectly spelled *Erechthites*.

Chemical Composition.—The properties of *Fireweed* appear to reside in a volatile oil (see *Oleum Erchitidis*), which may be obtained from the plant by distillation with water, and which possesses in an eminent degree the taste and odor of the plant, and which is very persistent.

Action, Medical Uses, and Dosage.—*Fireweed* is reputed to be emetic, cathartic, tonic, astringent, and alterative, of which the most valuable are the latter three. Reputed an unrivaled medicine in diseases of the mucous tissues of the lungs, stomach, and bowels. A spirituous extract of the plant has been highly recommended by Dr. A. R. Wyeth, of Pennsylvania, in the treatment of *cholera* and *dysentery*, in the latter disease promptly arresting the muco-sanguineous discharges, relieving pain, and effecting a speedy cure. In the *summer-complaint of children*, he has found it to prove almost invariably successful, even in cases where other means had failed.

Prof. Roberts Bartholow, at the instance of the authors of *Drugs and Medicines of North America*, experimented physiologically and therapeutically with true oil of *fireweed*. He found it to possess the general characteristics of the antiseptic group. It proved to be non-irritant to the stomach, and rather to improve the appetite and digestion. On account of its stimulating effects upon the gastro-intestinal glands, and probably upon the pancreas, an abundant secretion is poured out, rendering the alvine evacuations easy, frequent, and copious, thus proving very useful in *habitual constipation*, and especially benefiting such cases with acid fermentation and flatulence. He states that "in *membranous enteritis*, an affection difficult to cure, it has seemed to be, in a high degree, useful." It first stimulates the heart, dilates the arterioles, and sends a glow of warmth throughout the body. Secondly, perspiration ensues, the sense of warmth is succeeded by a lowering of temperature, slowing of the pulse, and contraction of the arterioles. Following this is a rise in vascular tension. It is rapidly diffused, absorbed quickly, and quickly excreted, elimination taking place most largely by the lungs, and less so by the kidneys and skin. He concludes that its most important therapeutical

action is in disorders of the parts by which it is eliminated, as *chronic bronchitis*, *pulmonic affections*, with catarrh of the air tubes, *chest neuroses*, and *coughs* of local origin. It may also be used by inhalation. Benefit was derived from its use in *genito-urinary catarrh*, *pyelitis*, *gleet*, *cystitis*, etc., the drug also allaying nervous irritability. Prof. Bartholow further suggests its value in "*sciatica*, *muscular rheumatism*, and *cognate affections*."

Prof. Hale, on part of the Homœopaths, gives quite a list of the effects of the oil in tincture, in large doses, and concludes that its action is chiefly upon the vascular system. As oil of fireweed upon the market is generally oil of fleabane, it is very probable that the product used by the Homœopaths has been the erigeron oil. However, oil of erechites is considered useful in *passive hemorrhages* from the kidneys, whether due to "*Bright's disease*" or other renal disturbances. It has been used also, like oil of erigeron, in *epistaxis*, *hemoptysis*, *hematemesis*, *profuse menorrhagia*, and *hemorrhage from the bowels*. According to Hale large doses will increase the menses and bring them on early if used continuously in cold, torpid, phlegmatic individuals. It is a remedy for *gonorrhœa*, *gleet*, and *gonorrhœal orchitis*. (See *Oleum Erechitidis*.) Dose, 5 to 10 drops of the oil upon sugar, in emulsion, or in capsules.

Specific Indications and Uses.—Catarrhal states of the mucous membranes; passive hemorrhages; "albuminuria, dropsy, pale, waxy skin, swelling of feet, scanty urine" (Watkin's *Comp. of Ec. Med.*).

ERGOTA (U. S. P.)—ERGOT.

SYNONYM: *Ergot of rye*.

"The sclerotium of *Claviceps purpurea* (Fries), Tulasne (*Class: Fungi*), replacing the grain of rye, *Secale cereale*, Linné (*Nat. Ord.—Gramineæ*). Ergot should be only moderately dried. It should be preserved in a close vessel, and a few drops of chloroform should be dropped upon it from time to time to prevent the development of insects. When more than one year old, it is unfit for use"—(U. S. P.).

Nat. Ord.—Fungi—Ascomycetes.

SYNONYMS: *Spur*, *Spurred rye*, *Smut rye*, *Ergot of rye*.

History and Formation.—Ergot is the sclerotium, the second, intermediate, or dormant stage of *Claviceps purpurea* (Fries), Tulasne, a fungus replacing the grain of rye (*Secale cereale*, Linné). *Ergot*, or *spur*, as it is sometimes called, was formerly regarded as a diseased grain of rye, but as now understood the grain of rye is simply replaced with the fungous growth. No transformation occurs as was supposed, but the tissue of the caryopsis of the rye is destroyed (*Pharmacographia*).

Ergot has been the subject of much investigation, particularly at the hands of Lévillé, Meyen, Tulasne, and others. De Candolle (1816), believing with others that ergot was a distinct and complete fungus, named it *Sclerotium Clavis*, while Fries denominated it *Spermatia Clavis*. Queckett called it *Ergotetia abortifaciens*, and Berkley, *Oidium abortifaciens*. Tulasne, however, placed it in the genus *Claviceps*, as an ascomycetous fungus, of which he described 3 species—one of which, the *Claviceps purpurea*, grows on rye, wheat, oats, and numerous pasture grasses. For a long period the ergotized condition of the rye was confounded with other and somewhat similar conditions met with in other cereals and in the fruits of sedges and grasses—parasitic maladies of crowded herbaceous plants growing side by side, year in and year out, in the same localities. The affection of the rye has been more thoroughly studied than some of those in other plants, probably on account of the former general use of rye as a food and the terrible consequences of epidemics of gangrene that have been traced to the contaminated grain, and also from the fact that it is one of the most important of medicinal substances.

Fig. 106.

1. Ear of rye with Ergot.
2. Ergot.
3. Ergotized rye

The generic name of the fungus, now recognized as the causative factor in the production of ergotized rye, is *Claviceps*, and is derived from the club-headed receptacles bearing the fructifications; the specific name, *purpurea*, refers to its purplish hue. The intermediate stage of the fungus is designated the *sclerotium*, *spur*, or *ergot*. *Sclerotium* signifies a hardened body, and *ergot*, derived from a French word (*argot*, a cock's spur), has reference to the spur-like shape of the sclerotium. The effect of the *Claviceps*, or fungus, is to apparently change the young fruit into an elongated, purplish-black, hard body which projects from the fruiting head of rye. This body is subcylindrical, curved, tapers bluntly at each extremity, and is an inch or more in length. Its outer surface is dark, being purple-black, while its interior is white and felt-like, being, in fact, "a densely compacted mass of fungus mycelium" (spawn, or branching network of *hyphæ*, which latter are thread-like bodies or cells, having a protective membrane of cellulose inclosing protoplasm). Besides the protoplasm the mycelium cells contain about 35 per cent of oily food materials. The dark, spur-like body is the *ergot*, and L'éveillé, a French botanist, was the first to show it to be an aggregation of mycelium at rest and not, as formerly supposed, a diseased grain.

Tulasne (1852), desirous of learning the fate of these bodies (ergot) after leaving the host plant (the rye), instituted experiments which led to the determination of the true character of ergot and the fungus of which it is a part. He began his experimentation by sowing a number of the sclerotia (ergot), and these, after remaining at rest upon damp earth for several months, began to put forth from their surfaces little nodules or hillocks which, by lengthening, formed rod-like projections (stipes) of thick, white material, capped at the free extremity with plump, rounded expansions or heads (*stroma*) of a violet color. At first these club-like projections were thought to be distinct parasites, but were later proven to be mere expansions of *hyphæ* growing out from the mycelium cells constituting the sclerotium, and pushing their way from their point of origin in the pale-white interior through the thin-purple coat. In time the surface of the little purple head or stroma was found to have developed minute papillæ, or wart-like projections, each presenting a minute orifice at its apex. The opening led directly into an ovoid cavity, directly below the papillæ, known as the *perithecium* (*conceptaculum*). Subsequently there arose from the base of this ovoid cavity (*perithecium*) long, thin, tubular bodies, denominated *asci* or *thece* (*spore-sacs*), as well as other *asci* in various stages of development. Inasmuch as the orifice of the papillæ leads vertically downward into the perithecium, the *asci*, whose long axes are also vertical to the surface of the stroma, point toward the orifice in the papillary elevation. Within each of these *asci* there are long, slender, thread-like bodies without color, and from 6 to 8 in number, termed *ascospores*. As these silky-white flocculent spores ripen they are shed as an agglutinated mass through the small orifices of the papillæ by the bursting of the *asci*, and are then carried about by insects, rains, winds, and like agencies. This usually takes place at about the same time that the cereals are beginning to blossom. If now the ascospores come in contact with the young flower of the rye, the latter is infected in the following manner, the result being that the mycelium takes possession of the base of the pistil. At various points the ascospores swell, and at these swellings give rise to small, slender branchlets, which quickly bore through the epidermis at the base of the flower. In about 10 or 12 days the lower portion of the flower is found to have been invaded by the mycelium, the slender, colorless *hyphæ* of which soon project from the surface and envelop the young pistil in complex folds. From the tips of the *hyphæ*, which terminate these folds, there "buds off" enormous numbers of very minute, colorless bodies, termed *conidia*, and at the same time the folds secrete a malodorous but viscid and sugary fluid of a yellowish color, which repels bees, but attracts flies, beetles, ants, etc., and is popularly known as the "honey dew." This saccharine fluid, in which are immersed the *conidia*, sticks to the proboscides, feet, and other parts of the visiting insects, and is thus carried to healthy flowers, where the *conidia*, in contact with the young flowers, behave exactly as do the ascospores—germinating and penetrating the pistil-base and developing in it a mycelium exactly like that produced by the latter, and which, in a few days, produces new *conidia* and fresh honey dew, thereby establishing a new source of infection.

The white mycelium and the honey dew with its contained conidia, constitutes what was formerly known as the *sphacelia*, a term indicative of the shrivelled gangrenous appearance of the tissues attacked. After the production of conidia and honey dew has progressed for several days, the pistil which normally would have developed into the grain, becomes a dead, shrivelled mass. The fact has already been referred to that the mycelium, which gives origin to the conidia and honey dew, has penetrated the floral base and pistil, forming in their tissues a dense, white felt-work. This now becomes more and more compact and increases in quantity, while the outer cells become first dark in color and then hard in texture, thereby developing the *sclerotium of the fungus*—the *ergot*, which, as its growth progresses and it becomes an elongated, spur-like body, carries before it the shrivelled, dead remains of the pistil and the *sphacelia*, which gave origin to the conidia. Thus the ergot matures just previous to the time for harvesting the rye and then drops off, rests upon the ground through the winter and early spring months, and in the summer germinates, and thus the ravages of the previous season are repeated. In this way it may go on for years, producing its *sphacelia* and developing its ergot parasitically upon the host plant, and then, after resting on the soil through the winter, it saprophytically develops its stromata upon the ergot-form or sclerotium.

It will be observed from what has been narrated, that the life history of *Claviceps* presents 3 stages of development: (1) The development of the *sphacelia*, with its conidia and honey dew; (2) the dormant state of the compact mycelium of the fungus, or the produced *ergot*; (3) the fructification of the ergot exhibited in the germination of the ergot-form producing the stromata, perithecia, asci, and ascospores. The ergot, therefore, is but the intermediate or resting stage of the development of this interesting fungus (*Claviceps purpurea*). The major portion of the preceding popular description of the formation of ergot was prepared from H. Marshall Ward's *Diseases of Plants*.

Ergot should be gathered previous to harvest, and is said by M. Bonjean to be much more active after the fifth day of its formation. When we examine a number of ears of ergotized rye, we find that the number of grains on each spike which have become ergotized varies considerably; there may be one only, or the spike may be covered with them. Usually the number is from 3 to 10. The mature ergot projects considerably beyond the paleæ. It has a violet-black color, and presents scarcely any filaments and sporidia. Ergot is met with in all climes where cereals are grown, the bulk of the commercial product coming from Vigo, in Spain and Teneriffe, while considerable quantities are furnished by southern and central Russia (see *Pharmacographia*).

Description.—Ergot of commerce consists of grains which vary in length from a few lines to 1 inch, or even $1\frac{1}{2}$ inches, and whose breadth is from $\frac{1}{2}$ to 4 lines. Their form is cylindrical or obscurely triangular, with obtuse angles, tapering at the extremities (fusiform), curved like the spur of a cock, unequally furrowed on two sides, often irregularly cracked and fissured. The odor of a single grain is not detectable, but of a large quantity is fishy, peculiar, and nauseous. The taste is not very marked, but is disagreeable and very slightly acrid. The grains are externally purplish-brown or black, more or less covered by a bloom, moderately brittle, the fractured surface being tolerably smooth, and whitish or purplish-white. Their specific gravity is somewhat greater than that of water, though, when thrown into this liquid they usually float at first, owing to the adherent air. The lower part of the grain is sometimes heavier than the upper (P.). When ergot is examined under the microscope, its internal part is seen to be composed of minute hexagonal or rounded cellular tissue, the cells containing from 1 to 3 globules of oil; its violet or blackish coat consists of a layer of longitudinally elongated delicate cells, and its blooms consist of sporidia. Unless kept carefully excluded from the air, it softens and swells, and becomes infected with numerous brown insects, about the size of a pin's head, while at the same time it acquires a deep-black color and heavier odor. Its powder quickly becomes damp, and full of animalcules. It should always be used recently pulverized, or, if kept in powder, it should be in well-closed and darkened vials, and with a few lumps of camphor added. It imparts its virtues to water or alcohol; long boiling renders it inert. The best ergot is dry, and easily broken, free from

insects, burns with a clear flame, and is incapable of forming a dark-blue pulp when its powder is triturated with iodine and water.

The *U. S. P.* requires that ergot should conform to the following description: "Somewhat fusiform, obtusely triangular, usually curved, about 2 or 3 Cm. ($\frac{3}{4}$ to $1\frac{1}{2}$ inches) long, and 3 Mm. ($\frac{1}{8}$ inch) thick, 3-furrowed, obtuse at both ends, purplish-black, internally whitish with some purplish striae, breaking with a short fracture; odor peculiar, heavy, increased by trituration with potassium or sodium hydrate T.S.; taste oily and disagreeable. Old ergot, which breaks with a sharp snap, is almost or entirely devoid of a pinkish tinge upon the fracture, is hard and brittle between the teeth, and is comparatively odorless and tasteless, should be rejected"—(*U. S. P.*). The *U. S. P.* directs the occasional addition of a few drops of chloroform to ergot to prevent the development of insects.

Chemical Composition.—Vauquelin is generally accredited with having made the first analysis of ergot of rye, but according to his own statements, a chemical analysis of ergot had been made by Model, of Strassburg, as early as 1766 (*Jour. Pharm. Chim.*, 1817, p. 164). Subsequent researches have brought out the most contradictory results, owing not only to the changeable character and the want of crystallizability, of the physiologically active drug constituents, but also to the tendency of various investigators to apply identical names to essentially different bodies, as well as to persistently uphold distinctions by name of substances that are essentially alike, if not identical. As a result, opinions are still divided, as to the chemical nature of the substances that constitute the active principles of ergot. Indeed, it seems as if this drug acts, as a whole, in a way that no constituent or mixture of products can do. At one time it was believed that the *fatty oil* which occurs in ergot in the amount of from 25 to 30 per cent, and upward, carried the medicinal properties of the drug, a belief probably due to the fact that the oil when obtained by expression or extraction with ether may hold in solution some of the active principles of ergot (*erboline*). However, it was found that by abstraction, with petroleum ether, or with benzin, no *ecboline* will pass into the fatty oil (J. Denzel, *Archiv. der Pharm.*, 1884, p. 314). The name *ergotin* has been applied to different substances by different authors. Wiggers (*Prize Essay*, 1831), extracted dried ergot, which had been previously deprived of its fatty oil by means of ether, with boiling alcohol, and after evaporating the solvent he treated the residue with water, which left the "*ergotin*" (*Chemisches Centralbl.*, 1832, p. 276). The *ergotin* of Bonjean (1843), was merely an aqueous extract of ergot purified by separating out gummy and albuminous matter by means of alcohol (*Amer. Jour. Pharm.*, Vol. XV, p. 219). W. T. Wenzell, in 1864, isolated from ergot, as he supposed, two alkaloids, *ecboline* and *ergotine*, which later investigators (e.g., Blumberg, 1878), pronounced identical. *Ecboline* possessed the physiological action of ergot to a powerful degree. Both alkaloids he found combined in the drug with a peculiar acid which he called *ergotic acid*. Besides he observed a volatile constituent, *propylamine*, which he pronounced identical with the volatile *secalinaline* previously observed by F. L. Winckler (1852). Walz established the presence of the volatile base, *trimethylamine*, which Brieger (1887) showed to be a product of decomposition of *cholin*, one of the constituents of ergot.

Tanret, since 1875, maintains that the active principle of ergot is represented by a crystallizable alkaloid which he called *ergotinine*, having the formula $C_{12}H_{16}N_2O_6$. Amorphous *ergotinine* he obtained as a by-product. Dragendorff and Podwissotzky (1876), observed the *ecbolic* principle of ergot to reside in two non-alkaloidal substances which they named *sclerotic acid* and *scleromucin*. The former, existing in good ergot in the amount of from 4 to 4.5 per cent, is soluble in alcohol of 80 per cent and less; the latter is soluble in alcohol of 40 per cent and less, both are soluble in water, and are difficult to obtain free from ash. If these substances are really the active principles of ergot, it becomes evident why it is not admissible to remove gummy and albuminous matter by the addition of an excess of strong alcohol. In this connection see the interesting papers by C. Lewis Diehl, and by Prof. Hallberg, in *Amer. Jour. Pharm.*, 1881 and 1883. Dragendorff and Podwissotzky, investigating also the coloring matters of ergot, found *sclererythrin*, *sclerodatin*, *scleroxanthin*, and *sclerocrystallin*, to which they added, in 1877, *picrosclerotine* (a poisonous, evanescent alkaloid, perhaps identical with Tanret's *ergotine*, etc.), and *fusco-sclerotic acid* (see *Jahresb. der Pharm.*, 1876-77).

In 1884, R. Kobert concluded from his researches that ergot contained three active principles, two of acid nature and one an alkaloid. *Ergotic (ergotinic) acid*, a glucosid containing nitrogen, is the principal constituent of *sclerotic acid* aforementioned, also of Bonjean's ergotin, and of the ergotin of Wernich, which he obtained by dialysis. It has the power of paralyzing the spinal cord, but does not produce ecboic action. *Sphacelic (sphacelinic) acid* is a resin free from nitrogen, probably the main constituent of the ergotin of Wiggers. It produces gangrene. *Cornutine*, an exceedingly poisonous alkaloid, according to Kobert is not identical with Tanret's ergotinine. Denzel (1884), however, believes it to be identical with Wenzell's *ecboline* which, in turn he thinks to be the same substance as Tanret's ergotinine; likewise he believes the acid principles, ergotic acid (Kobert), sclerotic acid (Dragendorff), and ergotic acid (Wenzell), to be identical. In 1894, C. C. Keller pronounced the identity of his *cornutine* with Tanret's *ergotinine*, Dragendorff's *picrosclerotine*, and Kobert's *cornutine*, on the ground that they all gave the same color reaction with concentrated sulphuric acid (a few mgr. of alkaloid first colored the acid yellowish, and after a few hours a permanent violet blue). Keller also gave directions for the assay of ergot for cornutine (see *Proc. Amer. Pharm. Assoc.*, 1895, p. 542, and A. R. L. Dohme, *ib.*, p. 263). Within the last few years (since 1895), Dr. C. Jacoby's researches have come to the front. In his latest experiments he strove to exclude the deleterious action of water, alkalies, and temperatures above 60° C. (140° F.), hence the substances he obtained have a just claim on our attention.

In 1895, the firm of C. F. Boehringer introduced Jacoby's *spasmotin* or *sphacelotoxin*, as a most active educt from ergot (*Pharm. Centralhalle*, 1895, p. 265). In 1897, however, Jacoby observed that this substance was not a simple body, but was composed of three chemically different substances, *chrysotoxin*, *secalintoxine*, and *sphacelotoxin* proper. The latter forms the basic principle of the others, and the relation is as follows: Sphacelotoxin + (inert) secalin = secalintoxine; sphacelotoxin + (inert) ergochrysin = chrysotoxin. Sphacelotoxin is a resin free from nitrogen, and combines the gangrenous with the uterine contractile action of ergot. Secalintoxin acts qualitatively like chrysotoxin, only the gangrenous action is more apparent on account of the greater tendency of the former to decomposition; hence the latter substance is preferred pharmacologically. In both cases sphacelotoxin, by decomposition in the organism, becomes the active principle. The mode of preparation and description of these bodies have recently appeared in print (*Pharm. Centralhalle*, 1898, p. 185), and may be summarized as follows: *Chrysotoxin* is a phenol-like body, also obtainable in crystalline form, having the composition $C_{11}H_{12}O_6$. It is prepared by depriving powdered ergot of its fat by means of petroleum ether, abstracting with strictly absolute ether, evaporating the solution to a syrup and precipitating with petroleum ether. By redissolving in ether and fractionally precipitating with petroleum ether, pure chrysotoxin is obtained. This substance is insoluble in water, diluted acids, and petroleum ether; soluble in ether, chloroform, alcohol, benzene, glacial acetic acid, etc. Caustic alkalies form golden-yellow solutions that are altered by warming. Prolonged contact with excess of alkali converts it into inert *ergochrysinic acid*, precipitable by acids. This is probably a constituent of Kobert's *sphacelinic acid*. Chrysotoxin is administered in the form of its sodium compound.

Secalintoxine is a pronounced alkaloid contained in the first fractions in the preparation of chrysotoxin. The impure chrysotoxin is dissolved in ether, the alkaloid shaken out with diluted acetic acid, and precipitated by means of sodium carbonate. In pure form it is soluble in alcohol, acetic ether, chloroform, benzene, less soluble in ether, little soluble in water and weak alkalies, and insoluble in benzin and petroleum ether. With concentrated sulphuric acid it gave Keller's *cornutine* reaction, without being identical with this substance, as both differ markedly in their physiological actions. Evaporated on the water-bath repeatedly with alcohol and concentrated hydrochloric acid, traces of the alkaloid leave a beautiful violet-colored residue. *Ergochrysin* is a yellow, inert coloring matter, soluble in water and in glacial acetic acid. *Secalin* is obtainable, in crystals of several millimeters in length, from secalintoxin. It is a pronounced alkaloid, yet stated to be not identical with Kobert's *cornutine*, nor Tanret's *ergotinine*, as it does not possess the contractile activity of the latter. It gives the

color reaction of secalintoxine in a more pronounced degree, and exhibiting a beautifully blue fluorescence in alcoholic solution. It has the formula $C_{12}H_{15}NO_6$. *Sphacelotoxin* is obtained as a yellow resinous mass which soon turns green, precipitating with petroleum ether an ethereal solution of secalintoxine. (1) of secalin are also formed. Decomposition of *secalintoxine* into its components, *lin* and *sphacelotoxin*, is best effected by means of lime. It contains much of nitrogen, and gives but faintly the secaline reaction above mentioned.

Other Constituents of Ergot.—Among these may be mentioned vegetable men (Wiggers, 1831); ash (5 per cent, especially rich in phosphates); acetic and formic acids, probably occurring in decomposed ergot only; as recorded by Schoonbrodt (1863), though Tanret (1889) considers it per ergot, naming it *ergosterin*. It is probably identical with the substance Wiggers, in 1831, named *cerin* (see Wiggers, *Jahresb. der Pharm.*, 1869, p. 25) (amidocaproic acid) *mannit*, and reducing sugar, are also present in ergot. W. observed a sugar peculiar to ergot, which was non-reducing and not fermentable. It was called *mycose* by Mitscherlich, and thought to be identical with *trehalose* by Muntz. Mucilage is present in ergot in appreciable amount. A lian, crystallizable body, *vernin* ($C_{12}H_{15}N_2O_4 + 3H_2O$), discovered by E. Sch. Von Planta, and found to occur in various plants, associated with asparagin, also been observed in ergot (see *Jahresb. der Pharm.*, 1886, p. 15).

In conclusion it may be said that notwithstanding the voluminous literature on this subject and the patient work devoted to the chemistry of ergot, much yet to be done when it comes to affiliating the chemical record and the theoretical constituents. It is evident, as before stated, that in therapy such preparations as liquids containing natural groups of constituents, made by methods do not use heroic chemistry, are as yet the logical preparations to be used by conservative physicians.

Detection of Ergot in Flour, Bread, etc.—Ergot may be detected when mixed with farinaceous substances, by the following method of M. W. Mix the suspected substance with a little water in a test tube, and cover with a layer of solution of caustic potash—if ergot be present, trimethylamine is evolved, which has an unmistakable odor of fish-brine; the application of heat favors the development of this substance, but likewise quickly dissipates it. Simply mixing the bread or flour containing ergot with milk of lime and allowing it to stand for some time, the odor just described becomes apparent.

Flückiger (*Pharmacognosie*, 3d ed., 1891), favors Hilger's color test, which is carried out as follows: Shake 10 grammes of the flour suspected of containing ergot with 20 grammes of ether and 10 drops of diluted sulphuric acid (sp. gr. 1.84) allow to stand for 6 hours, filter, and wash with sufficient ether to clear the filtrate. Add 10 drops of a solution of sodium bicarbonate (sat. soln.) in the cold, and shake; the red violet coloring matter, due to the presence of ergot, will then appear in the lower (aqueous) layer. The test gives good results even with 1 gramme of flour containing only 1 per cent of ergot. The coloration remains permanent for weeks. For further chemical and some microscopic tests, see Flückiger. To distinguish *fresh* from *old* ergot, Koster (*Arch. Pharm.*, 1885, p. 241), recommends macerating for some time 2 Gm. of the powder with 5 Cc. of ether. The resulting solution is colorless if the ergot is but yellowish if it is old.

Action, Medical Uses, and Dosage.—I. **ERGOT.** Ergot exerts a remarkable effect on the human system, more especially when its use has been persisted in for some time. Its most serious influences are those occasioned by the chronic use of affected rye as food, and which are manifested by certain symptoms of *ergotism*, which assumes two types—*convulsive ergotism* and *gangrenous ergotism*. The first form does not present well-defined pathological differences, though they determine termination. The first form is characterized by weariness, giddiness, muscular contraction, formication, dimness of sight, voracious appetite, loss of secretion, yellow countenance, convulsions, and death. The second is likewise accompanied by formication, voracious appetite, insensibility, and gangrene (either of the extremities, with dropping off of the toes. In doses of from 3 to 5 grains, and especially when the stomach is in an irritable condition, it frequently causes vomiting and nausea. When given in large doses, it is apt to affect

cerebro-spinal system, as known by restlessness, heaviness of the head, headache, vertigo, enlarged pupils, tinnitus aurium, and other symptoms of narcotism, with depressed heart and respiratory action, and gastro-intestinal irritation with sudden nausea and vomiting. These effects have been termed *acute ergotism*. It frequently lessens the action of the heart and arteries, though sometimes this is increased, with febrile symptoms, especially during parturition. A single dose, varying from 2 to 8 drachms, has occasioned vomiting, colic, pains, and headache; single doses of 20 to 40 grains have no great influence under ordinary circumstances.

The exact physiological action of ergot is still a matter of investigation, but the view chiefly held is that it acts mainly upon the vascular and nervous systems, as follows: Microscopic examinations of the retina, spinal and cerebral meninges, and of the frog's foot, show its power to contract the arterioles. Ergot depresses the heart and dilates the veins, the effect of which is a deficient supply of blood to the arteries, causing an inactive contraction or in reality an arterial collapse. To this result is due its effects upon the nervous structures, causing an anemia of the cerebro-spinal axis and ganglionic centers and of the organic muscular structures. The primary effect of ergot on the circulation is a fall in blood pressure, but its ultimate effect is to induce a rise in blood pressure.

The effects of ergot are not fully produced by the many so-called active principles of ergot. The action of ergotin, however, most closely resembles that of the parent drug. It has been shown by Köhler that Wiggers' ergotin has no effect upon the circulatory apparatus, but may induce intestinal cramps and violent gastro-intestinal inflammation, while Bonjean's ergotin is free from such effects, and slows the heart, contracts the arterioles, lessens temperature, and diminishes reflex phenomena. In very large doses the latter paralyzes the heart, and the muscular tissues fail to respond to the galvanic current. Ergotic acid is thought to be the active ingredient of Bonjean's ergotin. It must be used hypodermatically, as it is destroyed in the stomach. It undoubtedly has hemostatic power, but does not cause uterine contractions. *Sphacelic acid* and *cornutine* (chiefly the latter), are thought to be the effective agents in the induction of uterine contractions, and to the former have been attributed the gangrenous effects of ergot.

Ergot does not readily kill in a single large dose, fatal effects, when occurring, being developed from the long-continued use of small doses. A teaspoonful of tincture of ergot, taken 3 times a day for 11 weeks, was alleged to have caused the death of a woman 3 months pregnant. The only post-mortem features were inflammatory patches on the gastric mucous membrane (Taylor, *Med. Juris.*, p. 522). The treatment for acute ergotism is chiefly symptomatic. Cardiac stimulants, as caffeine, coffee, etc., or amyl nitrite by inhalation, may be employed. The hot bath and dry heat increase the effects of the medicinal treatment.

Medicinally, ergot is chiefly used on account of its power of promoting uterine contraction in *languid natural labors*. When thus employed, it produces a strong, continued, and, as it were, spasmodic contraction of the uterus, seldom permitting any relaxation until the child is born, and often continuing for some minutes after. The contractions and pains caused by ergot are distinguished from those of natural labor by their continuance; scarcely any interval can be perceived between them, but a sensation is experienced of one continued forcing effort. Sometimes ergot causes no unpleasant effects on the system; and likewise fails to excite uterine contractions, which will be found the case with other parturient agents. The causes of these failures are not known, being merely conjectural. It is said that ergot poisons the child and causes its death. This may, probably, sometimes be the case, but I am induced to believe that the fatality more generally ensues in consequence of the long-continued and constant pressure of the contracted organ upon the cord and fetus, causing its utero-fetal circulation to cease, and thus destroying it by asphyxia (J. King). In support of the view that ergot probably does not directly operate in a poisonous manner upon the child, may be cited the testimony of Uvedale West (see Taylor, *Med. Juris.*, p. 521), who administered ergot during the births of 173 children, only 5 of whom were still-born. In a state of pregnancy, ergot will undoubtedly occasion abortion, though it sometimes fails here likewise. However, many contend that it is incapable of producing abortion, but that it is effectual only after uterine contractions have already commenced—that, while it is an ecbotic it is not an

abortifacient. It also influences the non-gravid uterus, producing painful contractions or bearing-down pains, and on this account has been useful in checking *menorrhagia*, *uterine hemorrhage*, and in expelling *polypus masses*.

As a parturient, its use should always be avoided, if possible, in first labors, nor is it to be used in the early stage of normal labor. In our opinion there are but two chief indications for the use of ergot in labor, and these are *uterine inertia* and *alarming hemorrhage*, and as the latter is most frequently post-partum, a full hypodermatic injection of Lloyd's ergot should be given as soon as the head is born, when hemorrhage threatens. The conditions for safety and success are that the labor be somewhat advanced, the mouth of the womb being moderately dilated, that no mechanical obstruction to delivery exists, as deformity of the pelvis, rigidity of the os uteri, mal-presentation, or, disparity of the size of the child to the parts of the mother, and more especially that the only cause of the slow progress of labor is insufficiency of the uterine contractions in point of force or frequency. One or 2 drachms of the powder may be stirred in 4 fluid ounces of hot water, and, when sufficiently cool, may be given in teaspoonful doses every 10 minutes until labor pains are induced; usually in 15 or 20 minutes the labor pains increase in force and frequency, and gradually become continuous, and effect the expulsion of the child within an hour. A good fluid extract of ergot, or Lloyd's ergot (non-alcoholic), are equally as efficient as crude ergot. To simply increase labor pains already existing not more than 5 drops, every 20 or 30 minutes are required; when speedy expulsion is sought, the dose should be 1 fluid drachm, by mouth or hypodermatically, every half hour or hour. When to be used simply to facilitate labor which is slowly progressing, the following was advised by Prof. J. M. Scudder: R Specific ergot, ℥i; water, ℥ij. Teaspoonful every half hour or hour. Such doses exert a stimulant influence, strengthen uterine contractions, and aid dilatation of the os uteri. The cases usually calling for these doses are those with feeble circulation, puffiness of the face, and cedematous feet. If the os uteri be rigid, thick, and doughy, lobelia should be associated with it.

In cases where the child is dead, and circumstances require prompt delivery, as, where the patient is greatly exhausted, or where the system becomes very irritable, etc., ergot may be administered, provided there be no obstruction to a safe delivery. It may likewise be administered to facilitate *abortion* when it has once commenced, as well as to check *uterine hemorrhage* in the gravid or non-gravid state. It may likewise be given for promoting the expulsion of a *mole*, *hydatids*, a *clot of blood*, or other uterine contents, when the womb has once begun to act. The practice of administering ergot to cause the expulsion of the placenta is not to be commended, for some of the worst cases of placental retention, especially when the placenta is adherent, have been caused by the constant contraction produced, thus imprisoning the secundines until septic consequences have ensued. It is far better to remove the placenta by mechanical means, and then to use ergot in case hemorrhage of any consequence follows. Neither do we approve of the custom of administering to every parturient, at the close of labor, a dose of ergot. If there is a history of hemorrhage at or after previous confinements, or present indications of such an accident, or there is uterine inertia, such a procedure is permissible and often imperatively demanded. But where no hemorrhage occurs the imprisonment of placental tissues and other debris, as well as the increased severity of the after-pains that usually occur, are a sufficient protest in themselves against the indiscriminate employment of a remedy so productive of harm as ergot. Ergot should never be administered unless there be present or impending complications imperatively demanding its exhibition.

Ergot is an admirable remedy for *hemorrhage*, post-partum or otherwise. For this purpose ergotin (see below) is also frequently employed. It is useful in *epistaxis*, *hematemesis*, *hematuria*, *menorrhagia*, from large, spongy, subinvolted womb, especially in scrofulous subjects, and in *intestinal hemorrhage*. It is sometimes useful in the hemorrhages accompanying *typhoid fever*. It is particularly useful, combined with appropriate constitutional treatment, in a *hemorrhagic diathesis*. It has given good results in *hemorrhagica purpura*. *Dysentery*, with bloody evacuations, has been relieved by it, and given internally or applied by suppository, it has given relief in *hemorrhoids*. It forms an excellent adjunct in the treatment of *passive hemoptysis*, the following having proven very serviceable in our

hands: R Specific ergot, tincture of cinnamon (oil), and specific lycopus, aa fl3ij. Mix. Sig. Dose, 20 drops, in water, every hour until relieved. If the hemorrhage be active, 60 drops may be given every half hour. Prof. Locke advises (*Syllab. of Mat. Med.*, p. 386), the following at one dose, to be repeated every half hour if necessary: R Specific ergot, gr. x; ipecac, grs. ss; gallic acid, grs. ij. Mix. He advises the same in *post-partum hemorrhage*, and in *intestinal hemorrhage from typhoid fever*. The action of ergot is enhanced by the conjoint administration of specific geranium, gallic acid, hamamelis, cinnamon, or lycopus. For the hemorrhage from *cancerous growths*, Prof. Locke advises the dusting of the surface with finely-powdered ergot and covering with a cloth wrung from a weak phenol solution. Ergot has given good results in *aneurism*, especially when small, and is accredited very serviceable in *dilated heart*, without lesions of the valves.

Ergot has a decided action of the muscular fibers of the bladder. Large doses may contract the fibers so as to cause retention of urine. In *incontinence of urine* and other bladder affections due to relaxation of the sphincter vesicæ, specific ergot in doses of from 10 to 30 drops in water, render good service. It may be combined with buchu as follows: R Specific ergot, fl3ss; specific buchu, fl3j; simple syrup, fl3ijss. Mix. Sig. One teaspoonful 3 or 4 times a day (Locke). *Cystic paralysis* is sometimes relieved by ergot, and particularly when due to overdistension of the bladder. *Amenorrhœa*, due to relaxed uterine tissues, or to congestive conditions, is relieved by specific ergot in small doses, and it is useful in *leucorrhœa*, due to similar causes. It is also a good remedy in the congestive form of *dysmenorrhœa*; here it may be associated with other appropriate remedies. As before stated, it is doubted by many whether ergot will excite uterine contractions in any instance, unless a natural movement toward such action has commenced, but, as previously remarked, there is no doubt of its influence upon the womb at other times than that of parturition. There is abundant evidence that small doses of ergot have prevented *abortion*. For *uterine subinvolution* ergot is one of the most positive of remedies. In small doses it has been recommended in *painful dysmenorrhœa*, where membranous shreds pass off. Sometimes it has proved advantageous in *fever and ague*, but is rarely used for this purpose. The dose should range from 5 to 10 or 15 grains, or an equivalent amount of specific ergot, 3 times a day, but its use should not be persisted in too long, on account of its tendency to cause dangerous symptoms. It is not without value in *spermatorrhœa*, *gonorrhœa*, and *enlarged prostate*. Small doses relieve *false pains* associated with fullness and uneasiness of the genitalia, and *œdema* with dullness, hebetude, and tendency to coma (Scudder). In skin diseases it has had a limited use in *erythema*, *urticaria*, *prurigo*, *acne rosacea* (locally and internally) and *incipient furuncles* (locally). Locally, *seborrhœa* is well treated with the oil of ergot.

Ergot is valuable in certain forms of nervous diseases. According to Dr. Brown-Sequard, ergot diminishes the blood in the spinal cord, by causing a contraction of its blood vessels; dilates the pupil; acts more especially on the fibers of the womb and of the bladder and urethra, and appears to exert a more powerful influence on the inferior portion of the spinal cord. He suggested that it be used in the same forms of *paralysis and disease of the spinal cord*, as belladonna. *Bonjean's purified extract (ergotin)*, in the dose of from 2 to 10 grains, 2 or 3 times a day, is often employed in the *spinal and cerebellar lesions* resulting from *masturbation and sexual excesses*. The nervous disorders to which ergot is adapted are those of a *hyperemic or congestive character*, and it is always contraindicated by *anemia*. It has been found particularly useful in *congestive headaches*, and particularly *migraine*, with flushed face, full pulse, and suffused eyes. Its action upon the circulation closely resembles that of belladonna, and the general indications are much the same. In any trouble, "with enfeebled capillary circulation with tendency to congestion, especially of the nerve-centers, ergot may be prescribed with advantage" (Scudder). The indications are dull, full eyes, with pupillary dilatation, fullness of the veins, slow pulse, sighing respiration and tendency to coma. With these indications it has been found very serviceable in *paraplegia*, *cerebral hyperemia*, *chronic mania*, *recurrent mania*, *epileptic mania*, *acute myelitis*, *spinal congestion*, etc. In *mental disorders*, dependent on intracranial congestion or obstruction, with bleeding from the nose, dizziness, hebetude, or headache, and *tinnitus*, due to intracranial miliary aneurisms, ergot appears to render efficient service.

Fluid extract of ergot, or a paste of ergotin, locally applied, has been used in *follicular pharyngitis*. Foltz (see Webster's *Dynamical Therapeutics*, pp. 57-621) is a strong advocate of the use of ergot in diseases of the eye. This is the common use of the drug for *conjunctival congestion* and for the *hemorrhage* following *enucleation* of the globe, he advises it in the following conditions: *follicular conjunctivitis* and *keratitis*, in *follicular conjunctivitis* (claiming it better than any other drug), *ophthalmia neonatorum*, *incipient trachoma*, *phlyctenula*, with great vascularization, and *pinguecula*. He declares it of no service in *cleritis* or involvement of the deeper structures of the eye. As a collyrium, he advises Lloyd's ergot gr. xv to xxx to sufficient water to make $\frac{1}{2}$ fluid drachm. Foltz further recommends full doses (Lloyd's ergot, $\frac{1}{2}$ to 1 fluid drachm) in *congested retinal vessels*, *hyperemia of the optic disc*, and *hemorrhage into the vitreous humor*. In combination with boric acid he employs ergot locally by instillation in *purulent otitis media*, with little discharge and a turgid tympanic membrane. R. Boric acid, zj; fluid extract of ergot (Squibb's), flss. Mix. Triturate dry. Ergot has given relief in *exophthalmic goitre*. Ergot and ergotin, both locally and internally, have been very effectual in reducing *nasal hypertrophies*.

II. ERGOTIN.—The facility with which solution of ergotin may be effected in hypodermatic injections, its rapidity of action, and its efficiency, render it superior to any other mode of administration. Yvon's solution (see *Liq. Ergotin*) is locally available. (Bonjean's ergotin may be used for the same purposes.) When properly made it is innocuous, and occasions neither pain nor inflammation. It has been successfully employed in *post-partum hemorrhages*, the only urgent symptom observed being a sudden headache with vertigo, nausea, and epigastric pain, which passes off in a few minutes by placing the patient in a horizontal position, but no symptoms resembling those of poisoning. Its effects are better marked in *passive hemorrhages* due to inertia or atony of the uterus. The use of this solution by subcutaneous injections has likewise been found efficient in *external hemorrhagia*, *epistaxis*, *hemoptysis*, and other profuse and obstinate hemorrhages, *gastroenterorrhagia*, *enterorrhagia*, *cerebral hemorrhage*, and in *secondary hemorrhages* following *surgical operations*. They have likewise been of service in *uterine fibroids*, soft, vascular, hemorrhagic tumors, of rapid development during the pregnancy, being more readily influenced by the ergotin; while, on the contrary, the standing, hard, voluminous, stationary tumors, which have formed before or undergone fatty degeneration, especially with females who have reached or passed the critical age, are hardly, if at all, influenced by it. Subcutaneous injections of ergotin have also proved effective in *prostatic enlargement*, *goitre*, *prolapse of the rectum*, *purpura hemorrhagica*, *internal aneurism*, *diabetes insipidus*, *paralysis of the bladder*, and *enlargement of the spleen*, especially when the malarial influences. Ergotin has a special influence upon the fibers of the smooth muscles. M. Bernard, who has given considerable attention to the subject, has set up his conclusions as follows: Subcutaneous injections of ergotin act upon hemorrhages by causing contraction of the smooth fibers of the blood-vessels, and those of the organs enclosing them. They appear to act locally at the point of injection, the ergotin is in contact with the tissues, but this action does not appear to be independent of the influence of the nervous system. Contraction of the smooth vascular fibers acts especially by modifying the tension of the blood; contraction of the fibers of the organs containing them acts especially by effacing them, or compressing them. Injections of ergotin appear to act efficiently, even in hemorrhages of organs deprived of smooth fibers, or presenting few of them in their structure, as in *gastro-intestinal hemorrhages*, *hemoptysis*, and *epistaxis*. Hemorrhages of organs in which the smooth fibers predominate; that is to say, *hemorrhages of the uterus*, are almost constantly cured or ameliorated by injections of ergotin. Their influence is especially manifest in the gravid condition of the uterus, or in connection with it, as *moles* and *intra-uterine fibromas*. It is likewise very effective when the muscular fiber of the organ is healthy, even when a portion of the organ is already destroyed, as by *cancer*. In cases of *metritis*, and especially of *chronic growths*, their influence is about null. When carefully made, and a proper proportioned solution is employed, no serious symptoms result. Bartholin has successfully the hypodermatic injection of ergotin (2 grs.) for the radical cure of *varicocels*. Seldom more than two injections were necessary. The operation

very painful, and care must be exercised not to puncture the veins, the solution simply being injected among the vessels. *Varicosities* have been similarly treated.

The dose of ergotin, by hypodermatic injection, varies according to circumstances, from $\frac{1}{4}$ of a grain to 5 grains per day. Some practitioners have even exceeded this quantity, using from 8 to 10 grains daily. The quantity of Yvon's solution of ergotin will, therefore, be from $\frac{1}{4}$ of a minim to 5 minims per day. The fractions of a minim may be made by adding water to the solution, thus: To obtain $\frac{1}{4}$ of a minim, add 1 minim of the solution to 23 minims of distilled water; 4 minims of this mixture will equal the $\frac{1}{4}$ of a minim of solution. The injections should be made in the neighborhood of the diseased parts, and be repeated, according to the circumstances, every 2, 3, or 4 days. In *uterine myoma*, M. Gerard prefers to inject directly into the uterine tissue. In *profuse hemorrhages*, from 3 to 5 or 10 minims may be used at a time, and, if necessary, may be repeated every 4, 8, or 12 hours, according to the urgency of the case, and the effect of the agent. In *enlarged spleen*, from 1 to 5 grains of ergotin have been injected daily.

The dose of ergot depends upon the conditions for which it is to be used. For rapid expulsive purposes in labor, or for active hemorrhage, the dose ranges from 5 to 30 grains, or from 5 drops to 2 fluid drachms of the fluid extract, or 5 to 60 drops of specific ergot or Lloyd's ergot. Lloyd's ergot, being non-alcoholic and representing grain for minim, is an excellent preparation for hypodermatic use. For specific purposes the dose of good fluid preparations of ergot ranges from 1 to 5 drops, seldom exceeding 10 drops. Bonjean's ergotin may be given internally to the extent of 10 grains, half that quantity being about the limit for hypodermatic use. The large doses above given are seldom required, about $\frac{1}{4}$ the stated amount being usually administered. *Tanret's ergotinine* may be used subcutaneously in doses not exceeding $\frac{1}{4}$ grain.

Specific Indications and Uses.—Uterine inertia during labor, when conditions are otherwise favorable for a safe delivery; hemorrhage due to atony, with weak pulse, cold surface, and dilated (sometimes contracted) pupils; post-partum hemorrhage (large doses); to expel loosened foreign particles from the womb; congestion or hyperemia of any part; venous fullness; mental apathy; dullness, hebetude, and tendency to coma; fullness and uneasiness of genitalia, with cedema; congestive headache; hemiplegia and paraplegia, with hyperemia or congestion; feeble circulation; hyperemic or congestive eye and ear disorders; otorrhoea, discharge slight and membranè turgid.

Other Forms of Ergot.—**ERGOT OF WHEAT.** This form of ergot is hand-picked in France and Italy from the wheat intended for the manufacture of vermicelli, pastes, etc. The ergots are thicker and shorter than those from rye, are said to retain their good qualities longer, and to be free from the deleterious action of the latter.

ERGOT OF OATS.—More slender than the ergot of rye. Sometimes collected to mix with the latter, or to be sold per se (Le Perdriel, *Pharmacographia*).

ERGOT OF DISS.—From *Arundo Ampelodesmos*, Cirillo. A reed grass of North Africa. It was first detected in 1842 by M. Durien de Maisonneuve, in Algeria (E. M. Holmes, *Amer. Jour. Pharm.*, 1886, p. 203). It is from 1 to 3 inches long, about $\frac{1}{16}$ inch broad, curved, or if large, spirally twisted. Resembles ergot of rye in structure, and according to Lallemand, is said to possess double the activity of that product.

Ergot-yielding Plant.—**RYE.** The grain of *Secale cereale*, Linné. *Nat. Ord.*—Gramineæ. Rye has a stem 4 to 6 feet high, hairy beneath the spike, in a wild state seldom over a foot high. Leaves lance-linear, rough-edged, and rough above, glaucous; lower ones, together with their sheaths, covered with a soft down. Rachis bearded on each side with white hairs. Glumes subulate, ciliated, scabrous, shorter than the florets, taken together with their awns. Outer paleæ folded up, keeled, tri-nerved, with very long awns; the 2 nerves and awns very rough. Stamens 3. Ovary pyriform, pilose. Stigmas 2 (L.—W.). The native country of rye is not positively known, though supposed to have originated about the Caucasus; at the present day it is considerably cultivated among civilized nations. Ground into fine flour it is used as an article of diet in the form of bread or mush. Rye bread is not so light-colored, nor so readily digested as wheat bread. According to Einhof, the grain consists of about 64 per cent of meal, the balance being husk or bran, nearly 24 per cent, and moisture. The meal consists of starch 61.07, gum 11.09, gluten 9.43, albumen 3.23, saccharine matter 3.23, husk, salts, acid, etc. (P.). Rye is frequently attacked by the parasite *Claviceps purpurea* (Fries) Tulane, the result being the production of the fungus, *ergot*.

Rye-bread, or rye-mush, is laxative, especially to those unaccustomed to its use, and is sometimes taken to obviate *costiveness*. The dry flour allays the heat and itching of *erysipelas* and other affections of the skin when applied upon the affected parts. In the form of poultice it is often applied to discuss tumors or swellings, or to hasten their suppuration, when far advanced.

Green rye, when from 6 to 10 inches high, made into a salve by simmering in fresh oil, have known to cure several most inveterate cases of *tinea capitis*; to be applied twice a day (King).

ERIGERON.—CANADA FLEABANE.

The plant *Erigeron canadense*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES: *Colt's-tail*, *Canada fleabane*, *Scabious*, *Pride-weed*, etc.

Botanical Source.—This plant is known by the various names of *Corn-Pride-weed*, *Scabious*; also improperly called by some persons *Horse-weed*, *weed*, etc. It is an indigenous annual herb, with a high, branching, firm and brittle-hairy stem, from 6 inches to 9 feet in height. The leaves are lanceolate, and ciliate; the lower ones suberrate. The flowers are very numerous, white, and irregularly racemose upon the branches, constituting a terminal, oblong panicle. The involucre is cylindric; the rays minute, numerous, crowded, and short; and the pappus simple (W.—G.).

History.—This plant is common to the northern and central portions of the United States, growing in fields and meadows, by roadsides, and in waste places, flowering from June to September. The very small, inconspicuous rays, which are multitudinous, the elongated involucre, and the simple pappus, serve to distinguish it from other plants of the same family. The whole is medicinal, and should be gathered when in bloom, and carefully dried. It has a feeble but pleasant odor, and a subastringent and amarous taste, with serenity, and yields its properties to alcohol, or water by infusion. Its acridity is lessened by boiling, owing to the dissipation of its essential oil.

Chemical Composition.—Dr. Dupuy, who made an examination of the plant, found it to contain essential oil (see *Oleum Erigerontis Canadensis*), tannic acid, gallic acids, bitter extractive, etc. The oil is not astringent to the taste, but exerts a styptic influence upon the system. It is of a colorless, or pale-yellow color, and becomes darker-colored, and may be procured from the plant by distillation with water.

Action, Medical Uses, and Dosage.—This plant is slightly tonic, and more active diuretic and astringent properties. The infusion has been found to be efficient in *diarrhæa*, *gravel*, *diabetes*, *dropsical affections*, *dysuria of children*, *parotiditis*, and in many *nephritic affections*. *Erigeron* is extremely useful in the arrest of *capillary bleeding* from any organ liable to hemorrhage, and to arrest the watery secretions from the gastro-intestinal and renal tracts. For many years it has been a popular favorite to arrest *watery diarrhæa*, and for the early stage of *cholera infantum*, where the evacuations gush suddenly and copiously from the child, it will be found one of the most important agents at our command. The infusion of the fresh plant freely administered, should be used, and not only serves to check the diarrhæa, but also supplies the body with the fluid which is required to supply the loss of water occasioned by the depleting evacuations. Its use is suggested in *cholera*. The infusion may be given hot or sweetened, if desired, and will prove useful if it can be retained upon the stomach. A snuff of the powdered leaves has successfully checked *epistaxis*. In bronchial disorders with bloody expectoration, a syrup is effective. The infusion may be used to allay the cough and lessen expectoration in *pulmonary consumption*. Locally, an infusion is useful in *leucorrhæa*.

On account of its constringing power over the renal capillaries it has great value in *hyper-urination*, as in *simple diabetes*. The infusion is very serviceable in *hemorrhages* from the stomach, bowels, bladder, and kidneys. It is useful in *hemorrhagia* when not due to retained fragments of placenta, or other foreign bodies. *Passive hemorrhages* where stimulation is required are the cases for its exhibition.

The volatile oil of *Erigeron canadense* acts as an astringent, and may be used as a local application to *hemorrhoids*, *bleeding from small wounds*, etc., like *rheumatism*, *boils*, *tumors*, *sore throat*, and *tonsillitis*, in which it should be combined with goose-oil or some similar substance, being too acrid to use alone. Internally it will be found useful in *diarrhæa*, *dysentery*, *hemoptysis*, *hematemesis*, and *hematuria*. From 4 to 6 drops of it on sugar, or dissolved in alcohol, and given in a glass of water, will be found a powerful remedy in *uterine hemorrhage* and *menorrhagia*.

acting promptly and efficiently; it may be repeated every 5 or 10 minutes if required. The oil may be given in the profuse stage of *gonorrhœa*. The usual manner of administering it is in simple syrup. The plant may be given in the form of powder in doses of $\frac{1}{2}$ or 1 drachm; or the infusion, which is the best form of administration, may be given in doses of from 2 to 4 fluid ounces 3 or 4 times a day, and oftener in bowel complaints; the aqueous extract is worthless, but the fluid extract may be given in teaspoonful doses. Specific erigeron, 1 to 30 drops; oil of erigeron, 3 to 10 drops.

Specific Indications and Uses.—Capillary or passive hemorrhages; "painful diseases of the kidneys and bladder, and in diseased conditions of the mucous membranes attended with free discharges" (Scudder); choleraic discharges, sudden, gushing, and watery, attended with thirst and cramping pain; hematuria, metrorrhagia, hemoptysis, epistaxis, and hematemesis.

Related Species.—*Erigeron annuum*, Persoon; *Various-leaved fleabane*, *Common fleabane*, *White-weed*. This plant, also known as *Erigeron heterophyllum*, is the *Erigeron annuum* of Persoon, and many other celebrated botanists. It is a biennial herb with a branching root. Stems from 2 to 4 feet high, thick, branching, hispid with scattered hairs, terminating in a large, diffuse, corymbose panicle of large heads. Leaves hirsute, coarsely serrate; lowest ones ovate, contracted at base into a winged petiole; stem leaves ovate-lanceolate, sessile, acute, entire at both ends, highest ones lanceolate. Flowers numerous; disk-florets yellow; ray-florets capillary, white or purplish. Pappus plainly double, the outer a crown of minute chaffy-bristle-form scales; the inner of scanty capillary bristles which are deciduous, or entirely wanting in the ray. This plant is common to the United States and Europe, being a very common weed in fields and waste grounds from Canada to Pennsylvania and Kentucky, and flowering from June to August (W.—G.). Properties, constituents, and uses same as those of next species (which see).

Erigeron Philadelphicus, Linné; *Philadelphia fleabane*.—The *Erigeron Philadelphicus* is the *E. strigosus* of Willdenow, and the *E. purpureum* of Aiton. It is a perennial herb, with a slender, pubescent or hirsute, leafy stem, 1 to 3 feet high, loosely corymbed at the summit, bearing a few small heads on long, slender peduncles; root yellowish and branching. Leaves from 2 to 4 by from 6 to 9 inches, thin, with a broad midrib, oblong; lower ones spatulate, crenate-dentate; upper ones oblong-lanceolate, clasping by a heart-shaped base, subserrate. Flowers numerous; disk-florets yellow; ray-florets innumerable, very narrow, rose-purple or flesh color, twice as long as the hemispherical involucre. Pappus simple. The whole herb is pubescent. This plant is found growing in common with the preceding variety, flowering at the same period (W.—G.).

The medicinal virtues of this plant and the preceding are analogous, and they may be substituted the one for the other; they are, however, less astringent and more diuretic than the *E. canadense*. The plant should be gathered during the months of July, August, and September, or during the flowering season. They are slightly fragrant, have a subastringent, somewhat bitter taste, and yield their virtues to alcohol, or to water by infusion. Mr. F. L. John obtained from 17 pounds of the dried herb but a drachm of greenish-yellow, powerful, aromatic oil, with a disagreeable, bitter, pungent taste and sp. gr. 0.946 (*Amer. Jour. Pharm.* XXVII, 105). Diuretic, astringent, and tonic. The infusion is very efficient in *affections of the bladder and kidneys, dysuria, especially of children, painful micturition, various forms of dropsy, gravel, and in hydrothorax connected with gout*. It has also been recommended as a diaphoretic in *rheumatism, fevers, colds, etc.*, and as an emmenagogue in *suppressed menstruation*; and has been used with advantage in *gout, some forms of cutaneous eruptions, and diabetes*. Dose of the infusion, from 2 to 4 fluid ounces 3 or 4 times a day.

ERIODICTYON (U. S. P.)—ERIODICTYON.

"The leaves of *Eriodictyon glutinosum*, Benth" (U. S. P.) (*Eriodictyon californicum*, Benth; *Wigandia californica*, Hooker and Arnott).

Nat. Ord.—Hydrophyllaceæ.

COMMON NAMES: *Yerba santa*, *Mountain balm*, *Consumptive's weed*, *Bear's weed*.

ILLUSTRATIONS: Hooker's *Botany*, Beech's *Survey*, Plate 88.

Botanical History and Source.—This plant is generally known as *Yerba santa* (holy or sacred herb). It is shrubby, from 2 to 4 feet high, and is found growing in clumps, in dry situations throughout California, and northern Mexico, where it is very common in certain localities. The stem is smooth, branched usually from near the ground, and covered with a peculiar glutinous resin, which exudes abundantly from all parts of the plant, excepting the under side of the leaves. The leaves are thick, leathery, and evergreen, their upper surface being coated, somewhat like a varnish, with the aforementioned resin. They are alter-

nate, and attached by short petioles at an acute angle with the branch. In shape they are narrowly elliptical, from 2 to 5 inches long, and from $\frac{1}{4}$ to $\frac{1}{2}$ of an inch in width. They are acute, and taper to a short leaf-stalk at the base. The upper surface is smooth and dark-green in color (sometimes black when dry). The under surface has a large, prominent mid-rib, and a close network of veins, and is covered, between the veins, with a close, white tomentum, which gives the surface a milky color. The margin of the leaf is dentate, with numerous unequal teeth, which are undulate and blunt. The flowers are bluish, and borne in terminal clusters, which consist of from 6 to 10 close, 1-sided racemes, that unroll as the flowers expand. The calyx is hairy, about $\frac{1}{2}$ the length of the corolla, and deeply 5-parted, almost to the base. The corolla is broadly tubular, about $\frac{1}{2}$ an inch long, and has 5 short, obtuse, spreading lobes. The 5 stamens are included in the corolla tube. The pistil consists of a free, ovate, hairy ovary, and 2 slender, diverging styles, with club-shaped stigmas.

Fig. 107.

Eriodictyon glutinosum.
 $\frac{1}{2}$ natural size.

History.—*Eriodictyon* was mentioned by Prof. Maisch in March, 1875, at the meeting of the Philadelphia College of Pharmacy, a specimen of the plant being at the same time presented. The October *Eclectic Medical Journal* (1875) contained an article from Dr. J. H. Bundy, of California, upon "Yerba santa." This was followed by others, all speaking of it as *Yerba santa*. In February, 1876, Prof. J. M. Scudder received specimens of the leaves from Dr. Bundy, and immediately had them identified botanically by C. G. Lloyd. They proved to be *Eriodictyon glutinosum*. Prof. Scudder published the botanical name in the *Eclectic Medical Journal*, March, 1876, since which the plant has been generally recognized. The leaves are employed in medicine. They are fragrant even after long drying and exposure. Doubtless, oxidation or other modifications of the various resinous substances con-

tinually develops this fragrant principle, which seems not to be a volatile oil. The taste is aromatic and sweetish, eventually acrid to a slight extent, but not bitter. The after-taste is sweet, resembling dulcamara, and is accompanied by a flow of saliva.

Description.—*Eriodictyon* is thus described by the *U. S. P.*: "Oblong-lanceolate, 5 to 10 Cm. (2 to 4 inches) long, acute at the apex, and below narrowed into a short petiole, the margin sinuately toothed to nearly entire; upper surface green, smooth, and covered with a brownish resin; lower surface reticulate and minutely white-tomentose; odor somewhat aromatic; taste balsamic and sweetish"—(*U. S. P.*).

Chemical Composition.—The first article of interest regarding this plant, from a pharmaceutical point, appeared in the *Chicago Pharmacist*, February, 1876, from Mr. H. S. Wellcome. He gave a figure of the plant, and reported finding several resinous bodies. Mr. Charles Mohr (*Proc. Amer. Pharm. Assoc.*, 1879, and *Amer. Jour. Pharm.*, 1879, p. 545), upon distilling 10 pounds of the dried leaves with water, found the distillate free from volatile alkaloid, but it contained a small amount of an oily substance, of an aromatic odor and taste. The herb yielded to ether 8 per cent of a bitter, acrid resin, and to alcohol an inert resin; besides, Mr. Mohr found a peculiar, tannin-like glucosid, gum, green coloring matter, sugar, wax, etc. Rich. Thal, in 1883, announced the presence of *ericolin* ($C_{20}H_{30}O_5$), a glucosid, in this plant. Rother (1887) obtained an acid resin forming soluble compounds with bases; these compounds, by double decomposition, precipitate quinine from solutions of its salts in the form of salts of quinium-resin. The latter compounds are singularly soluble in ammonia (*Amer. Jour. Pharm.*, 1887, p. 225). In 1888, Quirini, by extracting the drug with carbon disulphide, obtained, beside a green resin, insoluble in benzol, *eriodictyonic acid* ($C_{20}H_{30}O_5$), in yellow, deliquescent plates, soluble in benzol, and melting at 86° to 88° C. (186.6 to 190.4° F.). They have a sweetish-acid taste, and are closely related to *phloroglucin*. Prof. J. U. Lloyd, who has prepared considerable amounts of the

fluid extract of this plant (dried), strongly favors alcohol as the best agent for extracting and permanently holding the proximate resinous principles in solution.

Action, Medical Uses, and Dosage.—Eriodictyon (or Mountain balm) has been recommended in the treatment of *laryngeal* and *bronchial affections*, and in *chronic pulmonary difficulties* generally. It has also been eulogized in the treatment of *asthma* and *hay-fever*, in combination with *Grindelia robusta*. That it possesses some efficiency as a stimulant, in the treatment of *chronic mucous affections of the respiratory passages*, is undoubtedly true; but that it deserves the high encomiums passed upon it in the treatment of *laryngo-bronchial* and *chronic pulmonary maladies*, admits of great doubt; at least, the writer has met with no success with it in any of the above diseases that was superior, or even equal, to the results obtained by some of our old and well-known remedial agents. It has likewise been advised in the treatment of *hemorrhoids*, and in *chronic catarrh of the bladder*. *Catarrhal gastritis* is said to have been successfully treated with it. The article is generally employed in the form of fluid extract and specific yerba santa. The dose of the former varies from 15 minims to 1 fluid drachm; of the latter, 10 to 30 minims, taken in a little syrup, and repeating the dose every 3 or 4 hours.

Specific Indications and Uses.—"Chronic asthma with cough, profuse expectoration, thickening of the bronchial mucous membrane, loss of appetite, impaired digestion, emaciation" (Watkin's *Comp. of Ec. Med.*). "Cough, with abundant and easy expectoration" (Scudder).

ERYNGIUM.—WATER ERYNGO.

The rhizome of *Eryngium yuccifolium*, Michaux (*Eryngium aquaticum*, Jussieu).
Nat. Ord.—Umbelliferae.

COMMON NAMES: *Eryngo*, *Water eryngo*, *Buttonsnake root*, *Rattlesnake's master*, *Corn snakeroot*.

Botanical Source.—This plant is an indigenous perennial herb, with a single stem, from 1 to 5 feet in height. The root is tuberous. Its leaves are from 1 to 2 feet long, by $\frac{1}{2}$ an inch to $1\frac{1}{2}$ inches wide, broadly-linear, parallel veined, taper-pointed, grass-like, ciliate, and armed with remote soft spines. The bracts are tipped with spines, those of the involuclers being entire and shorter than the heads. The flowers, which are white or pale and inconspicuous, are disposed in ovate-globose heads, which are pedunculate, and from $\frac{1}{2}$ to 1 inch in diameter. The calyx is 5-parted and permanent; the styles slender; the petals connivent, oblong, and emarginate, with a long, inflexed point. The fruit is scaly, top-shaped, and bipartite (W.—G.).

History and Description.—This plant is a native of the United States, growing in swamps and low, wet lands, from Virginia to Texas, and especially on the prairie lands. It flowers in August. The root is the medicinal part. It has a dark-brown, very knotty rhizome, wrinkled horizontally, with many fibers of the same color, growing downward, furrowed or wrinkled longitudinally, and from a line to a line and a half in thickness. Internally it is yellowish-white, of a peculiar odor, somewhat resembling that of *Iris versicolor*, and a faintly-sweetish, mucilaginous, aromatic taste, succeeded by bitterness, some degree of pungency affecting the fauces, and a very slight astringency. It is easy to pulverize. Water or spirit extracts its properties. It has not been analyzed, but is worthy of attention.

Eryngo was one of the earliest known remedies, and was declared by Dioscorides to be a specific against flatulence, hence the name *eryngium*, derived from the Latin *erynge*—Greek *erugge* (to eruct, to belch). Its common names are *water eryngo*, *button snakeroot*, *corn snakeroot*, and *rattlesnake's master*. It was formerly lauded as an effective agent for the cure of rattlesnake-bites, hence the name *rattlesnake's master* and *button snakeroot* applied to it. It was likewise used for other bites and stings. A piece of the root was chewed and applied to the wound; at the same time a portion of the juice was swallowed. Much was claimed for it, but probably its virtues were very much overrated.

Action, Medical Uses, and Dosage.—Eryngium is diuretic, expectorant, diaphoretic, and sialogogue. Large doses will cause emesis. The root, when masticated, produces a copious flow of saliva. As an expectorant and diaphoretic,

it is useful in *chronic laryngitis* and *bronchitis*, when there is free and abundant discharge of muco-pus. It has been recommended as a substitute for *senega*. It relieves *chronic pharyngitis*, when associated with laryngeal irritation. In *general debility* and *dyspepsia* it may be employed to improve the appetite and gastric functions. It is indicated here by persistent irritation with red and tender tongue, nausea, and easily provoked disgust for food. The *diarrhœa of dentition*, when most largely mucus, is controlled by eryngium. It has been a favorite drug in renal disorders, especially *gravel*, *chronic nephritis*, and *atonic dropsy*, when dependent on renal irritation. It lessens irritation of the reproductive organs of both the male and the female. By lessening the erectile power, it is valuable in those cases of *nocturnal emissions* accompanied by erection and urethral irritation, *pain in the testes*, and *irritation of the bladder*. It is frequently indicated in *gonorrhœa*, *gleet*, and *leucorrhœa*.

While a good remedy for the above-named purposes, it is as a remedy for *vesical and urethral irritation* that the drug is entitled to its high rank among specific medicines. It may be employed in acute or chronic inflammatory or irritative conditions, when accompanied by burning and itching in the bladder or the prostatic and spongy portions of the urethra. Uneasy sensations throughout the vesical, prostatic, and urethral portions of the urinary tract, which might lead to serious consequences, are relieved by it. Dull, aching, tenesmic pain is relieved by it combined with *gelsemium*. In *acute cystitis* it should be used with the indicated sedative. *Reproductive disorders of women*, with vesical complications, are readily controlled by it, being of special value where there is a burning, tenesmic pain—a condition frequently encountered in gynecological practice. It is particularly valuable in *dysuria* from irritation, and in cases marked by determination of blood to the bladder. It relieves the *painful urination* incident to *gonorrhœa*. Like *gelsemium*, it is a first-class remedy for *spasmodic urethral stricture*. In *chronic cystitis* it is valuable when the secretions are scanty and when triple phosphates are present. It is a good remedy for *vesical catarrh*. It is always indicated in renal diseases with deep-seated burning, or burning pain. *Urethral inflammation*, with difficult micturition and irritable urethra in the aged, are conditions to which it is particularly adapted. It is said to relieve *renal colic*, dependent on the passage of *renal calculi*. Its power here is not important, except when combined with other indicated remedies.

As with a large number of remedies, it has not escaped mention as a remedy for *sypilis* and *scrofula*. The pulverized root, in doses of 2 or 3 grains, has proved very effectual in *hemorrhoids* and *prolapsus ani*. Two ounces of the pulverized root, added to 1 pint of good Holland gin, has effected cures in obstinate cases of *gonorrhœa* and *gleet*; to be administered in doses of 1 or 2 fluid drachms 3 or 4 times a day. By some practitioners this root is employed as a specific in *gonorrhœa*, *gleet*, *mucus diarrhœa*, and *leucorrhœa*; used internally in syrup, decoction, or tincture, and the decoction applied locally by injection. Dose of the powder, from 20 to 40 grains; of the decoction, which was formerly principally used, from 2 to 4 fluid ounces, several times daily. The best preparation is specific eryngium, the dose of which may range from 1 to 20 drops, administered in water.

Specific Indications and Uses.—The indications for eryngium are burning pain, with vesical, renal, or urethral irritability; uterine irritation, with bladder disorders; painful micturition; frequent desire to urinate; frequent, scanty, and scalding urination; cystic uneasiness; pain in the bladder extending to the loins; scanty urine, with frequent and ineffective attempts to empty the bladder; vesical catarrh; mucous diarrhœa; dyspepsia, with persistent gastric irritation.

ERYTHRONIUM.—ADDER'S TONGUE.

The leaves and root of *Erythronium americanum*, Smith (*Erythronium lancolatum*, Pursh).

Nat. Ord.—Liliacæ.

COMMON NAMES: *Adder's tongue*, *Dog's-tooth violet*, *Yellow snowdrop*, *Rattlesnake violet*, *Yellow erythronium*.

Botanical Source.—Adder's tongue is an indigenous, perennial herb, with a cormus or bulb at some distance below the surface, which is white internally, and

fawn-colored externally. The scape is naked, slender, and 3 or 4 inches high. The leaves are 2, subradical, lanceolate, and involute at the point, pale-green, with purplish or brownish spots, about 5 inches long, and one of them nearly twice as wide as the other. The flower is single, drooping, yellow, liliaceous, spotted near the base, expanded and revolute in the sunshine, and closing somewhat at night and on cloudy days. The segments of the perianth are oblong-lanceolate, obtuse, the inner ones being bidentate near the base. Stamens 6, filaments flat, anthers oblong-linear. Ovary obovate; style club-shaped, longer than the stamens, 3-lobed at top, terminating in 3 undivided stigmas. The capsule is oblong-obovate, stipitate, and 3-valved; the seeds rather numerous and ovoid, with a loose membranous tip (W.—G.).

History.—This is a beautiful little plant, among the earliest of our vernal flowers, found in rich, open grounds, or in thin woods throughout the United States; it flowers in April or May. The bulb and leaves are the parts used, and impart their virtues to water. The leaves are said to be more active than the root, and the dried drug much less active than when freshly gathered.

Action, Medical Uses, and Dosage.—Emetic, emollient, and antiscrofulous when fresh; nutritive when dried. The fresh roots and leaves, simmered in milk, or the fresh leaves, bruised and applied as a poultice to *scrofulous ulcers* or *tumors*, together with a free internal use of an infusion of them, is highly recommended as a remedy for *scrofula*. The expressed juice of the plant, infused in cider, is reputed useful in *dropsy*, and for relieving *hiccough*, *vomiting*, and *hematemesis*. Twenty-five grains of the fresh root, or 40 of the recently dried root, will operate as an emetic, though this result is sometimes uncertain.

ERYTHROPHLEUM.—SASSY BARK.

The bark of *Erythrophleum guineense*, Don (*Erythrophleum judiciale*, Procter; *Fillæa suaveolens*, Guillemin and Perrottet).

Nat. Ord.—Leguminosæ.

COMMON NAMES: *Sassy bark*, *Mancona bark*, *Teli*, *Bondou*, *Bourane des foupes*. ILLUSTRATION: *American Journal of Pharmacy*, Vol. XXIII.

Botanical Source and History.—Sassy bark is obtained from a large forest tree of Western Africa, and was first brought into notice by Prof. Procter (1851), who referred it to the genus *Erythrophleum* (Afzelius), and named it *E. judiciale*. Upon subsequent examination, Lindley identified it as the *E. guineense*, G. Don (*Fillæa suaveolens*, Guillemin and Perrottet). The tree has a close resemblance, both in leaves and fruit, to the *Gymnocladus canadensis*, or *Coffee-nut tree* of the United States. The leaves are bipinnately compound, and have ovate, acute leaflets, which are smooth, coriaceous, and alternate. The flowers are in dense, terminal, compound racemes; they are regular, and have a 5-cleft calyx, and 5 petals, imbricated in the bud; the 10 stamens are distinct and perfect. The fruit is a thick, leathery, brown legume, containing from 3 to 5 oblong, flat, albuminous seeds. The tree, when wounded, yields a red juice (whence the generic name), which, like the bark, is used by the natives as an ordeal, and as a poison for their arrows.

Description.—The bark occurs in flattened, or more or less curved pieces, of various sizes, of a reddish-brown color, somewhat similar to the color of ferric hydrate, and usually having an external, corky covering, irregularly fissured; it is hard, friable, odorless, and astringent to the taste.

Chemical Composition.—Prof. Procter, Jr. (1851), examined the bark, but failed to isolate the poisonous principle; he predicted its separation, and remarked that when found, it would "possess great activity," a prediction since verified by N. Gallois and E. Hardy, who, in 1876, succeeded in obtaining the alkaloid *erythrophleine*, and demonstrating, by experiment, its fatal action upon animal life. *Erythrophleine* is an organic base, and may be obtained by extracting the bark with alcohol slightly acidulated with hydrochloric acid, evaporating the tincture to a small bulk, exhausting this, when cold, with warm distilled water, evaporating the resulting solution, adding ammonia (or sodium carbonate) to the residue until it has an alkaline reaction, and then agitating the mixture with acetic ether, from which the alkaloid may be obtained by evaporation. *Erythrophleine* is

crystalline, transparent, colorless, and soluble in water, acetic ether, alcohol, and amylic alcohol; only slightly soluble in ether, benzin, and chloroform. It forms salts with acids; is very poisonous, acting upon and paralyzing the heart. Curare, it is said, delays its effects. Boiled in the presence of diluted acids or alkalies erythrophleine yields *manconine*, a volatile, alkaloidal base, bearing some resemblance to nicotine, and a non-nitrogenous *erythrophleic acid*. Procter found both tannic and gallic acids, gum, resin, and other minor constituents.

Action, Medical Uses, and Dosage.—Sassy bark furnishes a red decoction, which is used by the natives on the western coast of Africa as an emeto-cathartic, and as a test for the detection of criminals; should it purge the person is considered guilty, but if it causes vomiting only, he is deemed innocent. The action of the bark has been investigated by Dr. T. Lauder Brunton and Walter Pye, Esq., in *Philosophical Transactions of the Royal Society*, Vol. 167, Part II, and by Santos, Liebreich, and others. Used hypodermatically, it is stated to produce vomiting, but no catharsis. In large doses it occasions a progressive stupefaction, when administered to animals, with complete muscular relaxation, paralysis of the heart's action, and death. During the progress of these effects there may also be observed a period of restlessness, succeeded by vomiting, quickened and labored respiration, and finally convulsions. With man it is said to produce vomiting, vertigo, muscular relaxation, gradual cessation of the heart's movements, with dyspnoea, convulsions, and death. The cause of its effects appear, according to investigators, to be owing to the fact that it contracts the blood vessels, thus occasioning an increased blood pressure, resulting in the symptoms named. The alkaloid, erythrophleine, was at one time recommended as a substitute for cocaine in eye surgery. Its effects on the conjunctiva and cornea are so severe, however, that this idea has been abandoned, as the untoward symptoms do not subside for several days. Besides it is charged with being painful, as well as provocative of inflammation, cloudiness, and exfoliation of the corneal structures. Therapeutically, it has been found efficient in those affections in which an agent was indicated, combining narcotic, astringent, and cholagogue properties, as in *diarrhœa*, *dysentery*, *passive hemorrhages*, etc. It has likewise been suggested in *dropsy*, due to obstruction of the mitral valves, and in *capillary hemorrhages*. Prof. Scudder states that it may be "given to stimulate the capillary circulation, to increase secretion of urine, arrested by feeble circulation, and to check *atonic diarrhœa*." For this purpose he suggests the minute dose, a teaspoonful of a solution of 1 drop of the tincture in 4 ounces of water. A tincture of the bark is probably the best form for administration in doses of from a fraction of a drop to 5 drops. Brunton and Pye consider the watery extract more powerful than the alcoholic. The powdered root is a violent sternutatory.

ESSENTIÆ.—ESSENCES.

Essences are alcoholic solutions of volatile oils differing from the official class of preparations known as *Spiritus* or *Spirits*, in strength only. Essences, as a rule, are about three times stronger than the spirits. The *British Pharmacopœia* recognizes two essences, *Essence of anise* and *Essence of peppermint*.

ESSENTIA ANISI, Essence of anise.—Mix 1 fluid ounce of oil of anise with 4 fluid ounces of rectified spirit. This is in accordance with the *British Pharmacopœia*. Properties same as oil of anise, which see. Dose, from 10 to 20 drops.

ESSENTIA MENTHÆ PIPERITÆ, Essence of peppermint.—Mix 1 fluid ounce of oil of peppermint with 4 fluid ounces of rectified spirit. This accords with the formula of the *British Pharmacopœia*. Properties those of oil of peppermint, which see. Dose, 10 to 20 drops.

EUCALYPTOL (U. S. P.)—EUCALYPTOL.

FORMULA: $C_{10}H_{18}O$. MOLECULAR WEIGHT: 153.66.

"A neutral body obtained from the volatile oil of *Eucalyptus globulus*, Labillardière, and of some other species of *Eucalyptus* (Nat. Ord.—Myrtaceæ). Eucalyptol should be kept in well-stoppered bottles, in a cool place, protected from light"—(U. S. P.).

SYNONYMS: *Cineol*, *Cajuputol*.

Preparation and History.—In preparing the oil of eucalyptus from eucalyptus leaves, that portion distilling between 170° C. (338° F.) and 178° C. (352.4° F.), is called *crude eucalyptol*. It may be purified by surrounding the crude eucalyptol by a refrigerating mixture, when eucalyptol separates in long, needle-like, colorless crystals. The crystals are then drained from their adherent oil, and the process of crystallizing is repeated several times. Eucalyptol may be obtained from other oils as well as from those of the various species of *Eucalyptus* (see *Amer. Jour. Pharm.*, 1889, p. 371). Thus it forms a constituent part of oils of cajuput and of rosemary, and is particularly abundant in the *Oil of Santonica*, from *Artemisia pauciflora*, Weber, which, in fact, is almost wholly composed of eucalyptol. Wallach and Brass, in 1884, prepared it from the latter oil by forming a crystalline compound with gaseous hydrochloric acid, pressing off the mother-liquor, liberating the eucalyptol with water, purifying with caustic potash in warm alcoholic solution, and finally drying and rectifying the oil. According to Schimmel's *Report* (April, 1891), eucalyptus oil from *E. oleosa* is also rich in eucalyptol, solidifying when put into a freezing mixture. Jahns, in 1885, found eucalyptol to possess the formula $C_{10}H_{18}O$, and to be identical with *cineol*, a substance obtained by Wallach and Brass, in 1884, from *oleum cynæ*, and found in turn to be identical with *cajuputol*, from oil of cajuput.

In 1895, Mr. Scammell, in Adelaide (Australia), took out a patent for the preparation of eucalyptol from oil of eucalyptus, the process consisting in the formation of a crystalline compound of phosphoric acid with eucalyptol, decomposable afterward by water into its constituents (*Pharm. Centralh.*, 1895, p. 419). A crystallizable acid may be produced by acting upon eucalyptol with nitric acid, while phosphoric anhydride (P_2O_5) converts it into *eucalyptene* ($C_{10}H_{16}$), and *eucalyptolen*.

Description and Tests.—“A colorless liquid, having a characteristic, aromatic, and distinctly camphoraceous odor, and a pungent, spicy, and cooling taste. Specific gravity, 0.930 at 15° C. (59° F.). Boiling point, 176° to 177° C. (348.8° to 350.6° F.). It is optically inactive (distinction from the oil of eucalyptus and many other volatile oils). When exposed to a temperature some degrees below 0° C. (32° F.), or placed in a freezing mixture, it solidifies to a mass of colorless, needle-shaped crystals, which liquefy at -1° C. (30.2° F.). Soluble, in all proportions, in alcohol, carbon disulphide, and glacial acetic acid. If a portion of eucalyptol be shaken with an equal volume of sodium hydrate T.S., it should not diminish in volume. Its alcoholic solution should be neutral to litmus paper, and should not assume a brownish or violet color on the addition of a drop of ferric chloride T.S. (absence of phenols)”—(*U. S. P.*).

Action, Medical Uses, and Dosage.—(Same as *Eucalyptus*, which see).

EUCALYPTUS (U. S. P.).—EUCALYPTUS.

“The leaves of *Eucalyptus globulus*, Labillardière;” “collected from the older parts of the tree”—(*U. S. P.*).

Nat. Ord.—Myrtaceæ.

COMMON NAME: *Blue-gum tree*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, Plate 109.

Botanical Source and History.—The genus, *Eucalyptus*, is noted as being an extensive and almost exclusively Australian family of trees; for, although 134 species are recorded by Benthams (*Flora Australiensis*), as natives of that continent, only 2 or 3 species are found to grow in any other lands. The *Eucalyptus* trees are very numerous in their native country, and constitute an important feature in every landscape. They are sometimes shrubs, but generally trees, which often attain gigantic size. Most of the species secrete a resinous substance, and hence are known to the Australian colonists as “gum trees.” The leaves, which are always entire, are very variable in shape and position. In the young trees they are always opposite and horizontal, but, in older trees, they generally become alternate, and, by a peculiar twist of the leaf-stalks, present the edges instead of the flat surfaces to the ground, thus giving the *Eucalyptus* a strange appearance, different from that of any of our American trees. The flowers of the *Eucalyptus* trees are generally in umbellate clusters. The calyx is partially adnate to the ovary, and furnished in the bud with a conical lid or cap, covering the stamens,

but which, when the flower expands, separates from the lower part of the calyx by a circular dehiscence, and falls off entire. There are no petals, but the stamens are numerous, and are sometimes united into 4 sets. The fruit, which is enclosed in the hardened calyx, contains 3 or 4 cells, and usually ripens 4 seeds to each cell.

The botanical history of the genus, *Eucalyptus*, is not yet thoroughly established. The leaves of the same species, at different stages of their growth,

Fig. 108.

Leaves and fruit of *Eucalyptus globulus*.

extremely variable, and the species are so numerous and so closely allied, that positive differences are very difficult to find. Botanists classify them by the bark, which is smooth, rough, or sometimes scaly.

Eucalyptus globulus.—This is one of the most valuable of Australian trees, on account of its timber, which is strong and durable. The tree, often exceeding 200 feet in height, is known to colonists as "blue-gum," and this name is applied to at least 6 other species. *Eucalyptus globulus* is placed, by Benth. (*Australiensis*), in the series Normales, with "perfect stamens with globular anthers opening longitudinally." The flowers are large and produced in axillary clusters of 19. The mature leaves are from 6 to 12 inches long, borne on wrinkled, twisted stalks, about 1 inch in length. They are narrowly lanceolate, with entire and thickened edges, obtuse or cordate at the base, and gradually tapering at the apex to an acuminate point. The texture is very firm, so that the leaves retain their shape without wrinkles when dried. They are confluent near the margin. The entire surface is thickly sprinkled with pellucid oil dots. The surface, when dry, with minute black specks.

The leaves of *Eucalyptus globulus* are native to Australia and adjacent countries, the popular remedy against fevers, especially in obstinate palustial fevers. They are firm, coriaceous, and, in the fresh state, resist the attacks of grasshoppers and locusts. They have a strong, aromatic odor, and a warm, bitterish, and aromatic taste, which, as with mint leaves, is followed by a cool sensation in the mouth.

Description.—The mature leaves, which are gathered from the older branches of the tree, are thus described by the U. S. P.: "Petiolate, lanceolate, rounded at the base, from 15 to 30 Cm. (6 to 12 inches) long, rounded below, tapering to the apex, entire, leathery, grayish-green, glandular, feather-veined between the primary and secondary veins; odor strongly camphoraceous; taste pungently aromatic, somewhat cooling, bitter and astringent"—(U. S. P.).

Chemical Composition.—The leaves have been analyzed by Cloez, Fremy, Homeyer, M. F. A. de Hartzen, and Prof. E. S. Wayne. According to Fremy, they contain tannin in quite a large proportion, resinous matter, and an essential oil (see *Oleum Eucalypti*), which has been found to consist chiefly of eucalyptol ($C_{10}H_{18}O$) (see *Eucalyptol*). Rabuteau failed to discover a basic principle. He freed an alcoholic extract of the leaves from oil, tannin, and resin. He found a white crystalline body, mixed with an amorphous resinous matter, which gave an acid reaction; an acid yellow resin, of bitter taste; an acid named eucalyptic acid, and a neutral, crystallizable, bitter substance, soluble in ether and alcohol, but only slightly soluble in water. Prof. E. S. Wayne obtained a crystallizable resin, capable of producing, with ferric chloride, a brown-red reaction.

Action, Medical Uses, and Dosage.—The oil of eucalyptus (which is eucalyptol) and eucalyptol, in small doses, are gentle stimulants; in large doses they occasion irritation of the throat and fauces, with increased flow of saliva, cephalalgia, with extreme fatigue; frequency of the pulse; increased temperature

diminution of vascular tension; gastric irritability, and, not unfrequently, diarrhoea, accelerated respiration, the peculiar odor of the oil being exhaled with the breath; and increase of the urinary excretion. In some instances a sort of intoxication results from large doses (20 drops) of eucalyptol, and large doses of it and of eucalyptus produce some drowsiness and lack of power over the limbs. The chief eliminatory organs appear to be the lungs and kidneys, the drug causing an increased elimination of urea. Locally, the oil is irritant, particularly if not allowed to evaporate.

Eucalyptus globulus has for a long time been known as a remedy for *intermittent fever* among the natives of the countries of its origin. It is stated that more than 40 years ago the corvette, "*La Favorite*," being in the vicinity of Botany Bay, had her crew nearly decimated by a *pernicious fever*, and that a perfect recovery ensued among those remaining upon using an infusion of the leaves of Eucalyptus; the credit of this discovery is given to Dr. Eydoux and M. de Salvy. Dr. Ramel, of Valencia, is said to have introduced the remedy into Europe, in a statement made to the Academy of Medicine, in 1866; since which period its therapeutical virtues have been examined by many investigators. The emanations from this tree have, it has been reported, a strong antagonistic influence against those conditions termed malarial, and, on this account, it has been cultivated in various places in Europe where these conditions appear to have had a permanent existence.

Notwithstanding the high encomiums passed upon this agent as an antipyretic by the majority of those who have tested it, there are certain other investigators who are less enthusiastic; thus, Dr. Burdell, who tested it in the miasmatic fevers encountered in the marshy district of Sologne, France, states that, though eucalyptus has been sometimes found a febrifuge nearly equal to quinine, at other times it has proven to be discouragingly inefficient. (Indeed, the same may be observed of quinine and all other remedies, unless specifically indicated.) After thoroughly testing it in 123 cases, he concluded that it possessed but little or no antimalarial power. He states that the cures effected by it have been more frequent in the hospital than in the palustral localities, and which may be readily accounted for. Very often, as Chomel has shown, persons attacked with intermittent fever are cured in the hospital without any medicines having been employed. Dr. Carlotti, of Ajaccio, considers a quickly made decoction of the leaves to be of great value in those cases of intermittent fever that do not yield to quinine. He gives the decoction in doses of from 2 to 5 fluid drachms. Prof. Locke states that it is not so useful in *recent ague* as cinchona bark, but better in *chronic ague*, "in cases attended with excessive discharges or drain upon the system, as *diarrhoea*, *dysentery*, etc." He recommends 10-drop doses of specific eucalyptus in *chronic obstinate diarrhoea*, when no ague is present.

Aside from its alleged utility in intermittents, this agent has had other virtues attributed to it, as follows: The leaves and their preparations have been successfully used as a tonic and gently stimulating stomachic, in *atonic dyspepsia*, and in *catarrh of the stomach and typhoid fever*; also advised in *mucous catarrhal affections* generally; in *pseudo-membranous laryngitis*, in *asthma*, with profuse secretion, and in *chronic bronchitis*, with or without *emphysema*, and in *whooping-cough*; it has likewise proved efficient in *chronic catarrh of the bladder*, where the urine is high-colored, contains an abnormal amount of mucus, or, perhaps, some purulent matter, and micturition is attended with much pain. More recently it has been recommended as a diuretic in the treatment of *dropsy*. Both the leaves and the oil, as well as eucalyptol, are excitants and deodorizers, and, as such, have been successfully employed as local applications in *bronchial affections* with fetid expectoration, in *ozena*, in fetid or profuse mucous discharges, in *vaginal leucorrhoea*, offensive lochial discharges, *gonorrhoeal discharges*, *indolent, fetid wounds or ulcers, cancerous ulcerations*, in *septicemia*, and in *gangrene*. An excellent application in *leucorrhoea*, with relaxation of the vaginal walls, is prepared as follows: R Sea salt, 1 lb.; fluid extract of eucalyptus, fl̄ss. Place the salt in an earthenware or tin vessel, and pour upon it the extract and mix thoroughly. A half ounce of this preparation may be added to 1 pint of hot water and injected by means of a glass or metallic syringe. M. Bucquoy has found eucalyptus to exert a happy influence in the treatment of *pulmonary gangrene*. M. Luton, and others, have derived considerable benefit from it, when locally applied in *cancerous affections*, in the

form of a compress of lint moistened with the tincture. It has likewise been advised to prevent putrefaction of organic substances, and to deodorize rooms and apartments containing unhealthy air. The leaves may, in some cases, be applied alone, directly to the part, in form of cataplasm; or they may be combined with other articles to form a poultice. The oil may be applied with strength, or diluted with some other agent. In throat and pulmonary troubles, a tincture diluted, or a medicated water, may be inhaled in the form of steam; the oil be employed, it may be dropped on some cotton placed in a vessel from which the vapor may be inhaled. As a deodorizer, the tincture or oil may be sprinkled or sprayed upon the offensive body, or the atmosphere of an apartment may be frequently sprayed with the same. Eucalyptol acts in a manner like the oil and both somewhat resemble turpentine in their effects. *Eucalyptus*, it is used in *foul and purulent respiratory diseases*, particularly *febrile rhæa*, *chronic bronchitis*, *pulmonary gangrene*, and *pulmonary tuberculosis*, etc.

The dose of eucalyptol and of the oil is from 2 to 10 drops, and it is most convenient to administer it in capsules. One part of either combined with ten parts of cod-liver oil has proved serviceable in *phthisis*; it removes the taste and odor of the fish oil. Eucalyptol is now given in many instances where the oil was formerly administered on account of the greater definiteness of dose, as the oil depends for its virtues upon the percentage of eucalyptol. Both have been given for the relief of *migraine*, and, externally applied, for relief in some forms of *neuralgic* and *rheumatic pains*.

The leaves of eucalyptus, made up into cigars or cigarettes, and smoked, have been advised to afford relief in *bronchial catarrh*, *asthma*, and other affections of the respiratory organs. The question has been asked, may not the small amount of benefit that might be derived from the minute proportion of oil remaining in the smoke be more than overcome, and even prove injurious, from the irritating action of the smoke and of the empyreumatic products?

The most agreeable and convenient forms of administration are the oil in doses of 10 to 30 drops; or the fluid extract in doses of 5 to 30 drops; or, preferable to all, specific eucalyptus, from 10 to 30-drop doses in the troubles, and from 5 to 10-drop doses in other troubles. It may be given in glycerin or syrup, as it does not mix well with water. The dose of the oil or eucalyptol is from 5 to 10 minims, preferably in capsules.

EUCALYPTUS HONEY, gathered by bees from eucalyptus flowers, is quite palatable and has been recommended for *parasitic* and *putrescent conditions*, *gonorrhœa*, and *catarrhal diseases*. It is sedative to the heart, actively diuretic, and promotes the elimination of uric acid.

Specific Indications and Uses.—Sensations of coldness and weight in the bowels; cold extremities; cold perspiration; perspiration during chill; *catarrhal diarrhœa*; chronic vesical catarrh, the urine containing pus; fetid secretions from any part; relaxed mucous tissues, with profuse watery, pasty, badly-smelling coating upon the tongue; fetid false membranes; secretions with fetid odor; fetid and catarrhal states of the broncho-pulmonic tract in large doses, in chronic ague with exhausting discharges.

Related Drugs.—**EUCALYPTI GUMMI.** This new addition to the British Pharmacopœia is furnished by the bark of *Eucalyptus rostrata*, Schlechtendal, as well as other species of *Eucalyptus*. It is an exudation from the bark and has a ruby-red color, and is the so-called kino from these trees. It resembles kino, though less astringent and possessing a brighter color. It has a bitter taste. When pure, it is almost entirely dissolved by alcohol; when added to water, forms a solution containing from 80 to 90 per cent of the drug, having a bitter taste (see *Botany Bay Kino*). Dose, 2 to 10 grains. For an account of the properties of this gum, see P. L. Simmonds, *Amer. Jour. Pharm.*, 1895, p. 132.

Anacharis Alsinistrum.—This plant is a native of Canada, and is credited with antimalarial properties. When introduced into districts where *malaria* and *malarial diarrhœa* are prevalent, it is said to diminish the number of cases of these disorders (*Medical Bulletin*).

EUONYMUS (U. S. P.)—EUONYMUS.

"The bark of the root of *Euonymus atropurpureus*, Jacquin"—(U. S. P. Nat. Ord.—Celastrineæ).

COMMON NAMES: *Wahoo*, *Indian arrow-wood*, *Burning bush*, *Spindle tree*.

Botanical Source.—This is a small shrub or bush, with smooth branches, and rising from 5 to 10 feet in height. Its leaves are from 2 to 5 inches in length, about half as wide, opposite, on petioles $\frac{1}{2}$ to 1 inch in length, elliptic-lanceolate, mostly acute at base, finely serrate, and pubescent beneath; the peduncles are opposite, slender, compressed, from 1 to 2 $\frac{1}{2}$ inches in length, each with a cyme of from 3 to 6 flowers. The flowers are dark-purple, and usually pentamerous; the corolla about 2 $\frac{1}{2}$ lines in diameter, flat, inserted on the outer margin of a glandular disc; the calyx flat, of 4, 5, or 6 united sepals; the stamens 5, with short filaments; the capsule or pod smooth, crimson, 5-angled, 5-celled, and 5-valved; the seeds, 1 or 2 in each cell, are inclosed in a red aril (W.—G.).

History.—There are two species of *Euonymus* used in medicine—the spindle-tree, *E. atropurpureus*, and the burning bush, or *E. americanus*, to both of which the term *Wahoo* is indiscriminately applied. They grow in many sections of the United States, in woods and thickets, and in river bottoms, and flower in June. The bark of the root is the medicinal part. It has a bitter, and somewhat unpleasant taste. Water or alcohol extracts its virtues.

Description.—The *U. S. P.* thus describes this drug: "In quilled or curved pieces, from 2 to 5 Mm. ($\frac{1}{4}$ to $\frac{1}{2}$ inch) thick; outer surface ash-gray, with blackish patches detached in thin and small scales; inner surface whitish or slightly tawny, smooth; fracture smooth, whitish, the inner layers of a laminated appearance; nearly inodorous; taste sweetish, somewhat bitter and acrid"—(*U. S. P.*).

Chemical Composition.—Charles A. Santos found in the aqueous distillate of the bark of *Euonymus atropurpureus*, a volatile oil (*Amer. Jour. Pharm.*, 1848, p. 83). Clothier, in 1861, detected starch, glucose, and pectin matter. In the following year Mr. Wm. T. Wenzell (*Amer. Jour. Pharm.*, 1862, p. 385), found a non-crystallizable, bitter principle, *euonymin* (not to be confused with the old Eclectic concentration of that name), *asparagin*, crystallizable and non-crystallizable resins, fixed oil, malic, citric, and tartaric acids, the peculiar *euonic acid*, and inorganic salts. The name euonymin was first affixed to the dried powdered solid extract about 50 years ago, and was included among the Eclectic resinoids or concentrations. This is the only preparation used in medicine under the name euonymin, and must not be confused with the definite, proximate principle that follows, and which is only of chemical interest. *Euonymin*, as obtained from *E. atropurpureus* by Prof. Meyer and Dr. Romin, of Dorpat, by an elaborate process (*Pharm. Centralk.*, 1885, p. 220), is a crystalline glucosid which corresponds in its physiological action closely with digitalin. It is sparingly soluble in water and ether, and easily soluble in alcohol. In 1884, H. Paschke (*Pharm. Centralk.*, p. 196), called attention to the occurrence of *mannit* as a seemingly regular constituent of all species of *Euonymus*. Naylor and Chaplin (*Chemist and Druggist*, 1889, p. 822), identified a certain sweet substance which they had obtained from *Euonymus atropurpureus* and provisionally named *atropurpurine* a few months before, as *dulcit* ($C_6H_{12}O_6$), which is an isomer of mannit.

Action, Medical Uses, and Dosage.—*Euonymus* has been in use among physicians for a long time. The bark is tonic, laxative, alterative, diuretic, and expectorant; the seeds are cathartic and emetic. In infusion, syrup, or extract, it has been successfully used in *intermittents*, *dyspepsia*, *torpid liver*, *constipation*, *dropsy*, and *pulmonary affections*. Prof. Locke states "there are but few good stomach tonics, and this agent is one of them." It stimulates the biliary flow, and has considerable anti-malarial influence, and may be used in intermittents after the chill has been broken with quinine. It stimulates the nutritive processes and improves the appetite. It may be used with advantage in *atonic dyspepsia*, and in *indigestion* due to hepatic torpor or following malarial fevers. It is a remedy for *chronic ague*, and the consequent *obstinate constipation* and *gastric debility* accompanying or following it. A gin tincture (root \mathfrak{zj} to gin $\mathfrak{f}\mathfrak{3}\mathfrak{v}\mathfrak{i}\mathfrak{i}\mathfrak{j}$), is not without value in some cases of *dropsy*, particularly when associated with hepatic and renal inactivity. Dose of the tincture ($\mathfrak{z}\mathfrak{v}\mathfrak{i}\mathfrak{i}\mathfrak{j}$ to alcohol 76 per cent \mathfrak{Oj}), from 1 to 4 fluid drachms; of the syrup, from 1 to 2 fluid ounces; of the hydro-alcoholic extract from 5 to 15 grains; of the powder, from 20 to 30 grains; of specific euonymus, 1 to 30 drops.

Specific Indications and Uses.—Prostration with irritation of the nerve centers; periodical diseases, to supplement the action of quinine; anorexia, indigestion, and constipation, due to hepatic torpor.

Related Species.—*Euonymus americanus*, Linné, or *Strawberry-bush*, is of a size than the preceding variety, with smooth, 4-angled branches; leaves oval and serrate, sessile, subentire at the margin, acute or obtuse at apex, smooth, coriaceous, 1½ inches in length, about one-third as wide. Peduncles round, longer than the fruit, 2, 3, or 4 flowers. Flowers somewhat larger than those of the preceding variety; pink; capsule dark-red, rough-warty, depressed, not so copious as in the former part. Uses similar to those of the preceding species.

Euonymus europæus, Linné; Europe.—Cultivated somewhat in gardens. It has lance-oblong leaves, smooth, shining, and serrate, and bears a flattened, 3-flowered and greenish-white, 4-parted flowers. The capsule is light-red, and the arillus is red color. It is not hardy in northern latitudes. In 1833, Riederer isolated in a state a body which he thought to be an alkaloid, and gave to it the name *eunomine*, a body he believed to impart the bitter taste to the bark. According to Gruber, it is simply a mixture of bitter extractive and resin. Kubel extracted a body resembling to mannit, to which he gave the name *eunomine*. It is a crystallizable principle differing from mannit in the fusing point and in crystalline structure (Pharm., 1862). All species of *Euonymus* possess an orange coloring matter, and having this characteristic color may be obtained from the arillus of the European by means of pressure. The fruit of this, as well as of the foregoing species has been a ointment form for the destruction of lice. All parts of the plant are nauseous, as purgative, while the leaves are said to poison sheep and cattle.

EUPATORIUM (U. S. P.)—EUPATORIUM.

"The leaves and flowering tops of *Eupatorium perfoliatum*, Linné" — (*Eupatorium connatum*, Michaux).

Nat. Ord.—Compositæ.

COMMON NAMES: *Thoroughwort*, *Boneset*, *Indian sage*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 147.

Botanical Source.—*Boneset*, or *Thoroughwort*, as it is also called, is an indigenous perennial herb, with a horizontal, crooked root. The stems are

Fig. 109.

Eupatorium perfoliatum.

stout, rough, hairy, and from 1 to 5 feet high. The leaves are opposite, connate-perfoliate, each part resembling a single leaf centrally perforated by the petiole, placed at right angles to it; they are rough, serrate, tapering to a long point, very rough beneath, and both combined are from 8 to 14 inches in length. The flowers, which are numerous and are arranged in dense, fastigate, terminal corymbs, heads are about 12-flowered; the scales of the involucre are linear-lanceolate, imbricated, tubular, with 5-spreading segments, and the pappus is down-like pappus, and the anthers blue or red, included. The style is filiform, and divided into filiform, acuminate branches, which project from the corolla. The fruit or seeds are oblong, black, mastic, acute at base, and supported on a narrow stalk (W.—G.—L.).

History and Description.—This is a very common plant, growing in low grounds and on the banks of swamps, streams, etc., throughout the United States, flowering in August and September. The tops and leaves are the parts used. Alcohol or boiling water extracts its medicinal properties. *Boneset* is officially described as: "Leaves opposite, united at the base, lanceolate, from 10 to 15 Cm. (4 to 6 in.) long, tapering, crenately serrate, rugosely veined, rough above, downy and obscurely dotted beneath; flower-heads corymbous, numerous, with an oblong involucre of lance-linear scales, and with from 10 to 15 white florets, having a bristly tip in a single row; odor weak and aromatic, taste astringent and bitter."

Chemical Composition.—Mr. W. Peterson (*Amer. Jour. Pharm.*, 1851) isolated from the aqueous extract of the leaves of *Eupatorium perfoliatum* successive treatment with alcohol, subacetate of lead and ether, a microcrystalline (feathery), very bitter substance, soluble in ether, but slightly soluble in water. Chlorophyll, gum, tannic acid, yellow coloring matter, salts, etc., were also observed by him. Mr. Parsons (*Amer. Jour. Pharm.*, 1879, p. 34).

over 18 per cent of bitter extractive "soluble in water and alcohol, insoluble in ether." In the following year, Mr. George Latin (*Amer. Jour. Pharm.*, 1880, p. 392), found in the alcoholic extract made of the leaves and the tops of the plant, a crystallizable body, probably wax or resin, and *eupatorin*, the bitter principle which he proved to be a glucosid, soluble in alcohol, chloroform, ether, and boiling water. It develops a raspberry-like odor when heated with diluted sulphuric acid (Latin), or with diluted hydrochloric acid (Franz). A volatile oil was also observed. A complete analysis of the leaves alone is recorded by F. W. Franz (*Amer. Jour. Pharm.*, 1888, p. 77), while the root has been analyzed by H. F. Kaercher, who found nearly 5 per cent of *inulin* to be present (*Amer. Jour. Pharm.*, 1892, p. 511). C. H. Shamel obtained *eupatorin* both in amorphous and crystalline states by extracting an alcoholic extract with acidulated water, and abstracting the bitter principle with ether after neutralization with sodium carbonate. This substance, which is free from nitrogen, forms a well-crystallizable nitrate of the formula $C_{12}H_{19}HNO_3$ (*Amer. Jour. Pharm.*, from *Amer. Chem. Jour.*, 1892, p. 224).

Action, Medical Uses, and Dosage.—This is a very valuable medicinal agent. The cold infusion, or extract is tonic and aperient; the warm infusion diaphoretic and emetic. As a tonic, it is useful in *remittent, intermittent, and typhoid fevers, dyspepsia, and general debility*; and combined with bitartrate of potassium and camphor, the powdered leaves have been serviceable in some forms of *cutaneous disease*. In *intermittent fever*, a strong infusion, as hot as can be comfortably swallowed, is administered for the purpose of vomiting freely. This is also attended with profuse diaphoresis, and sooner or later by an evacuation of the bowels. During the intermission, the cold infusion or extract is given every hour as a tonic and antiperiodic. It is not well adapted to ordinary cases of *ague* which may be cured with quinine, but is more particularly useful in the irregular cases which that drug does not seem to reach. The chill and succeeding fever is slight, the skin dry, and not, as a rule, followed by perspiration; there are "pains in the bones, præcordial oppression, and great thirst. If, however, the case is one in which the fever lasts all day, a slight sweating may follow at night. Another indication in *ague* is vomiting, especially of much bile" (Locke). *Eupatorium* given as above, or sometimes in small doses, may relieve *headache* of intermittent character when the intermissions are irregular. In *epidemic influenza* the warm infusion is valuable as an emetic and diaphoretic, likewise in *febrile diseases, catarrh, colds*, with hoarseness and pleuritic pains, and wherever such effects are indicated. In *influenza* it relieves the pain in the limbs and back. Its popular name, "boneset," is derived from its well-known property of relieving the deep-seated pains in the limbs which accompany this disorder, and *colds and rheumatism*. Often this pain is periosteal, and if neuralgic in character, or due to a febrile condition, *eupatorium* will relieve it. But it is not a remedy for periosteal pain due to inflammation or to organic changes in the periosteum. On the other hand, when given until the patient sweats, and then continued in 5-drop doses of specific *eupatorium*, it has relieved the severe *nocturnal muscular* and "bone pains" of *syphilis*. In *pneumonia*, if an emetic is indicated in the early stage, this agent is as efficient as any that may be used; but it is of greater value in the latter stage when given as a syrup. This is kindly received by the stomach, improves digestion, and allays the irritable cough. It is a remedy for the *cough of the aged*, that cough in which there is an abundance of secretion, but lack of power to expectorate. The *cough of measles, common colds, of asthma, and hoarseness* are also relieved by it. Unless given in excess it acts as a good tonic to the gastric functions, increasing the appetite and power of digestion. The *stomach disorders of the inebriate* are, in a measure corrected by the use of small, tonic doses of *eupatorium*. Although slightly stimulant, it is of service in most *inflammatory states*, administered according to the indications given below. The warm infusion may be administered to promote the operation of other emetics. Externally, used alone or in combination with hops or tansy, etc., a fomentation of the leaves applied to the bowels has been useful in *inflammation, spasms, and painful affections*. Dose of the powder, from 10 to 20 grains; of the extract, from 2 to 4 grains; of the infusion, from 2 to 4 fluid ounces; of the syrup (1 pint of the decoction of 1 ounce of the herb sweetened with 2 pounds of white sugar), 1 to 4 drachms; specific *eupatorium*, 1 to 60 drops. As an emetic administer the warm infusion freely.

Specific Indications and Uses.—Pulse full and large, the current of little waves; skin full and hot with a tendency to become moist, even in the progress of fever, cough, embarrassed breathing, and pain in the chest; or, if the pulse is small and rapid, the skin cold and clammy, the respiration stertorous, the micturition frequent; deep-seated aching pains in muscles and joints.

EUPATORIUM PURPUREUM.—QUEEN OF THE MEADOW.

The root of *Eupatorium purpureum*, Linné.

Nat. Ord.—Compositæ.

COMMON NAMES: *Queen of the meadow*, *Joe Pye weed*, *Trumpet-weed*, *Gravel-root*, *Joe-pie*, *Purple boneset*.

Botanical Source.—This plant is herbaceous, with a perennial woody caudex, with many long, dark-brown fibers, which send up several solid, glabrous, green, sometimes purplish stems, 5 or 6 feet in height, simple band at the joints, about an inch broad. The leaves are from 3 to 6 inches apart, oblong-ovate, or lanceolate, pointed, rugosely veined, coarsely serrate, slightly scabrous, with a soft pubescence beneath the mid-vein and veinlets, thin, soft, borne on petioles an inch long. The flowers are all tubular, pinkish-purple, varying to whitish, and consist of numerous florets in an 8-leaved calyx. The heads are in lax, very dense and compound of a cylindrical form, and from 5 to 10-flowered (W.—G.).

History and Description.—Queen of the meadow grows in low woods or meadows, in the northern, western, and middle states, from August and September. Its trivial name, Joe Pye weed, is said to have been attached to it through an Indian of that name, who lived in New England, and employed it as a diaphoretic in low fevers. The root is the medicinal part found in commerce, it consists of a blackish, woody caudex, from which numerous long fibers, from 1 to 3 lines in diameter; externally they are with a dark-brown, longitudinally-furrowed cortex, beneath which the pith is white, or whitish-yellow, according to its age, the last color being the oldest. It has an odor somewhat resembling old hay, and a slightly mucous, and faintly astringent, but not unpleasant taste, and yields its virtues to water by decoction, or to spirits.

Chemical Composition.—Mr. J. B. Robinson, formerly of Cincinnati, maintained what he thought to be the active principle of the root, in the form of a dark-brown, solid resin, to which he gave the name *eupatorine*. It possessed a peculiar, slightly bitterish taste, but its therapeutical virtues were not ascertained. In 1876, Prof. J. U. Lloyd donated to Prof. Maisch a specimen of a neutral, crystallized principle from the root of *Eupatorium purpureum*. This principle was quite soluble in hot, slightly so in cold alcohol, and insoluble in water; it did not unite with dilute acids and was decomposable by strong sulphuric acid. As far as known to Prof. Lloyd, it was new to science and had no medicinal properties. Mr. Lloyd's method of making this principle (*euparin*) is quoted by Prof. Lloyd in the *Amer. Jour. Pharm.*, 1890, p. 76. These crystals were found to be associated with a crystalline deposit afterward observed by Mr. E. G. Eberhardt, and having the composition $C_{22}H_{34}O_8$. It was not soluble in water, but with quercitrin or quercetin. This formula was confirmed by C. C. Marcet in the *Jour. Pharm.*, 1894. A complete analysis of the drug was made by Mr. J. G. Gigney (*Amer. Jour. Pharm.*, 1888, p. 121), and by Mr. G. H. Ray (*ib.*, 1890, p. 121). The latter found volatile oil, fat, wax, yellow resin, soluble in ether, and glucose, calcium oxalate, etc.

Action, Medical Uses, and Dosage.—Queen of the meadow has a subastringent, stimulant, tonic, and antilithic properties. It has a special influence upon the renal tract, increasing both the fluid and solid constituents of the urine. As its influence upon the stomach is good, it may be used for a great time without ill results. While a fairly good remedy in some forms of acute and chronic mucous diseases of the gastro-intestinal tract, its chief value lies in its efficiency in many disorders of the urino-genital passages. That it is a very valuable remedy in urinary calculi and gravel is admitted by many who can be

that it has the power to dissolve the concretions. That it is serviceable is probably due to its control over *vesical irritation*, while, by its diuretic action, it may prevent the formation of these bodies. For this purpose the following preparations and doses may be used: The infusion, 1 to 2 fluid ounces; the tincture, 5 to 15 drops; specific gravel-root, 5 to 10 drops. Gravel-root has been used with excellent effect in *dropsical affections*, due to renal inaction, being especially valuable in *anasarca*. After the removal of the effusion by catharsis, this agent may be administered to restore tone to the kidneys and to stimulate the absorbents, thus preventing the reaccumulation of the effusion. From 5 to 10 drops of specific gravel-root, in a teaspoonful of water, may be given every 3 hours, provided the patient is not greatly debilitated. *Post-scarlatinal dropsy* is benefited by it.

Gravel-root is a superior remedy for many painful and irritable states of the urinary tract. Difficult and painful micturition, with frequent desire to urinate, the passage seemingly being obstructed, is an indication for this drug. It is indicated also by pain and weight in the loins, extending to the bladder, with the scanty voiding of high-colored urine, or when mixed with blood or solids. The special sedatives may be associated with it when there is vascular excitation. *Chronic vesical irritation*, a sense of heat being experienced in the bladder, and the urine milky and loaded with mucus, the deposit adhering to the vessel, are further indications for its selection. It is a remedy for *strangury*, especially that resulting from fly-blisters or irritating diuretics, with shooting, darting urethral pains, vesical tenesmus, and frequent micturition. In *strangury*, Prof. Locke recommends a rectal injection of 30 drops of tincture of opium in starch water, followed by the free administration of infusion of queen of the meadow. Keep the patient warm, and if this treatment is not fully effective, associate with it the hot hip-bath. *Hematuria* has been well treated with it, as have also those disagreeable sensations due to recent prostatic trouble, the active stage having passed.

In that form of *urinal incontinence* of children, in which the vesical irritation is so great that the presence of a few drops of urine in the bladder causes a contraction and expulsion of the contents of the organ, give 5 drops of specific gravel-root 3 times a day, the last dose upon retiring. The same dose or the infusion will allay the *irritable bladder of pregnancy*, and the agent is not without value in *diabetes insipidus*. With the *vomiting of pregnancy* there is sometimes associated a *cough*, and at each effort at coughing a little urine is expelled. In these cases give 1 or 2-drop doses of specific gravel-root every 2 or 3 hours; if marked nervousness is a complication give *pulsatilla* also. It is regarded more efficient than most diuretics in *albuminuria*. As a remedy for *chronic urinary disorders* it is a very useful agent, and fulfils many important indications.

Queen of the meadow is asserted to be of value in *gout* and *rheumatism*. In those subject to *chronic cough*, associated with a weak circulation, and in individuals suffering from *asthma*, *chronic catarrh*, and unduly prolonged *whooping-cough*, it has rendered very good service.

Impotence is somewhat improved by the use of gravel-root, and in female disorders it is quite an important remedy. It controls *chronic irritability of the womb* and is beneficial in atonic states of that organ. When *habitual abortion* is due to *prolapseus*, *retroversion*, *debility* resulting from *chronic inflammation*, or other atonic states of the uterus, the tendency may be corrected by administering 5-drop doses of specific gravel-root 3 times a day. Used as an injection alone, or with some other astringent, it is of service in *chronic amenorrhœa*, with great debility and a continuous *leucorrhœal flow*. Dose of the decoction of queen of the meadow is from 2 to 4 fluid ounces, 3 or 4 times a day; of the tincture (℥viij to alcohol, 98 per cent, Oj), 1 to 30 drops; of specific gravel-root, 1 to 30 drops, every 1 to 4 hours.

Specific Indications and Uses.—Vesical irritation; incontinence of urine; painful and frequent urination; urine scanty and milky, with mucoid or bloody admixture; uric acid diathesis; pain and weight in the loins extending to the bladder; skin hot, dry, and constricted.

Derivatives and Related Species.—EUPURPURIN. This is a member of the list of remedies once known as resinoids or concentrations. Being of an oleaginous nature it was included with the *oleoresins*. The late Mr. William S. Merrell first prepared this oleoresin, and named it. It may be obtained by adding the alcoholic tincture of the root to twice its volume of water.

and distilling off the alcohol, similar to the process for obtaining resin of podophyllum, oleo-resin of blue flag, etc., or better, by concentrating the alcoholic percolate of the drug by distillation and then pouring the thick residue into cold water. It is of a thick, pilular consistence and a dark greenish-brown color, having a faint peculiar smell, and a slightly nauseous taste. It is soluble in alcohol, more speedily when hot. Eupurpurin, or the oleoresin of queen of the meadow, as thus prepared by Mr. Merrell, was formerly regarded a valuable agent in many renal and genito-urinary affections; in doses of 3 grains, repeated every 3 or 4 hours, it is a most powerful diuretic. It may be given in pill form, either alone or combined with an equal quantity of castile soap. An excellent pill for many renal affections is composed of eupurpurin, 30 grains; extract of geranium, 20 grains; and extract of nux vomica, 1 grain. Divide into 10 pills. One of these pills may be given every 4 hours daily. Eupurpurin is scarcely ever employed at the present day, having given place to the more representative liquid preparations of the plant.

Eupatorium leucifolium, Willdenow (*Eupatorium verbenzifolium*, Elliott); *Wild horehound*, *Rough boneset*.—This is an indigenous, perennial plant, with an herbaceous, paniculate, pubescent stem, growing from 2 to 3 feet high, with fastigiate, corymbose branches above. Leaves opposite, sessile, distinct, ovate-oblong, ovate-lanceolate, rough, veiny, lower ones coarsely serrate toward the base, upper ones alternate, subserrate, often entire. Branches of the corymb, few, unequal. Flowers small, white, consist of 5 florets within each calyx; scales of the involucre oblong-lanceolate, rather obtuse, at length shorter than the flowers (W.—G.). This plant grows in moist places from Canada to Florida, flowering in September and October. The whole plant is medicinal, possessing properties analogous to boneset, but not so unpleasantly bitter. Its active properties are taken up by alcohol or hot water. Tonic, diaphoretic, diuretic, and laxative. Recommended by Dr. Jones, of Georgia, in *intermittent and remittent fevers*. It stimulates the sympathetic functions, and improves digestion and blood-making. Usually administered in infusion; 1 ounce of the dried leaves infused in a quart of water, of which half a teacupful may be given every hour or two, as warm as can be comfortably drank. It will prove diaphoretic or diuretic, according to the temperature in which the patient is kept, and likewise laxative. The cold infusion, or tincture, is tonic. The dose of a strong tincture ranges from 1 to 20 drops.

Eupatorium aromaticum, Linné; *White snake-root*, *Aromatic eupatorium*, *Hemp-weed*.—This is a perennial plant, with a rough, slightly pubescent stem, about 2 feet in height, corymbose at the summit. Leaves from 2 to 4 inches long, about $\frac{1}{2}$ as wide, on petioles not quite an inch long, opposite, subcordate, lance-ovate, acute, 3-veined, obtusely serrate, smoothish, or very slightly pubescent. Involucre simple, pubescent; scales of the involucre nearly equal, in one row; flowers white, aromatic, in small corymbs; heads large, 10 to 15-flowered (W.). This is an indigenous plant, growing from Massachusetts to Louisiana, but especially throughout the middle states, and flowering in August and September. The root is the medicinal part, and should be collected in September and October. It has a pleasant aromatic odor, and a bitterish taste. Its virtues are extracted by boiling water. An aromatic body, very much resembling coumarin, if not that principle itself, has been obtained from this plant, and also from *Eupatorium incarnatum*, Walter. Twenty-five grains of volatile oil were obtained by Chas. H. Blouch from 5 $\frac{1}{2}$ pounds of the rhizome of *Eupatorium aromaticum* (White snake-root) by distillation with water (see *Amer. Jour. Pharm.*, 1890, p. 124). Diaphoretic, antispasmodic, expectorant, and aromatic. Its influence upon the brain is pronounced, relieving irritation and producing normal functional activity. Used in the form of infusion or decoction in *fevers of a typhoid character*, connected with wakefulness; also in *pleurisy and pneumonia*, as a diaphoretic and expectorant. In *hysteria, hypochondria, nervous irritability, and flatulence*, it is very beneficial; also reputed to have effected cures in *aphthæ, nursing sore mouth, chronic bronchitis, and chronic irritation of the bladder*. Dose of the infusion or decoction, from $\frac{1}{2}$ fluid ounce to 4 fluid ounces; of specific white snakeroot, 1 to 30 drops, well diluted, every 2 to 6 hours. It is sometimes combined with sanguinaria and aclepias, in pulmonary diseases. Said to be valuable in gravel.

Eupatorium sessilifolium, Linné; *Upland boneset*.—New England, western and southern states. Open woods in dry and mountainous situations. Said to possess properties similar to, though weaker than boneset. Tonic.

Eupatorium rotundifolium, Willdenow; *Round-leaved hemp-weed*; *Wild horehound*.—From Canada to Texas. Infusion has been employed in phthisis.

Eupatorium ageratoides, Linné; *White snake-root*.—Rich woods of Canada and the United States. Diuretic, diaphoretic, and antispasmodic.

Eupatorium hyssopifolium, Linné, and *Eupatorium leucolepis*, Torrey and Gray, both called "*Justice's weed*," have been used with success for curing the *bites of snakes and poisonous animals*. They were employed for this purpose by John Justice, of South Carolina, in 1800, who received a premium for disclosing his remedy. The former grows in dry situations from Massachusetts west and south; the second in the sands from Long Island south.

Eupatorium cannabinum.—Europe. Cathartic.

Eupatorium aya-pana.—Brazil. Leaves once much used as an aromatic, bitter tonic; resembling in properties the *Eupatorium perfoliatum*, though weaker in action.

Eupatorium villosum, Bitter-bush.—Jamaica. Stimulant, bitter, and tonic. Employed in low stages in *symptomatic disorders* as a general tonic. It is also used in the making of beer in Jamaica.

Mikania Guaco, Willdenow. *Nat. Ord.*—Compositæ. This is a South American climbing vine, closely allied to the Eupatoriums. The leaves are supposed, by the natives, to be a remedy for the *bites of poisonous serpents*, a property which they also attribute to *Eupatorium aya-pana*. The leaves of *Mikania scandens*, an herbaceous twiner, common to the eastern United

States, probably possess similar properties. This plant has been employed in *scrofula*, in certain *cutaneous maladies*, in *chronic rheumatism*, in *diarrhœa*, and in *cholera infantum*. It has been administered in decoction, in syrup, and in fluid extract; the dose of the latter being from 15 to 60 minims, 3 or 4 times a day. Age impairs the virtues of the plant. Dr. Hancock denies that this is the correct counter-poison, *guaco*, which he states is an *Aristolochia*.

Ageratum conyzoides.—Brazil. Reputed emmenagogue (Barker Smith).

MATA.—A Texan herb, probably the *Eupatorium incarnatum*, Walter. In New Mexico it is smoked with tobacco, and, having in itself a tonka odor, is said to modify the disagreeable odor of stale tobacco smoke, as taken up by garments and apartments (see *Amer. Jour. Pharm.*, 1868). An aromatic principle, resembling, if not identical with *coumarin*, has been obtained from *Eupatorium incarnatum*, Walter.

EUPHORBIIUM.—EUPHORBIIUM.

A gum-resin from *Euphorbia resinifera*, Berg.

Nat. Ord.—Euphorbiaceæ.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 240.

Botanical Source.—This leafless, cactus-like plant is a glaucous perennial growing 6 feet or more in height. Its ascending stems are fleshy and 4-angled, each side of the stem about 1 inch in width. The stems have spreading branches whose angles are clothed with divergent, horizontal stipules of a spinescent character taking the place of leaves. These are arranged in pairs and converge at the base into an ovate, somewhat triangular disc; above each pair of spines is a depressed spot indicative of a leaf-bud. The flowers, which are borne on stalks on the summits of the branches, are 3 in number, 2 of them being borne on pedicles. The branches abound in a milky juice, which exudes and concretes on the surface of the plant when it is wounded.

History.—Formerly it was not positively known from what plant this gum-resin was obtained, though Pereira believed it to be the *Euphorbia canariensis*, of the Canary Isles. From investigations by Berg, however, this view would seem to be erroneous, and the latter has established beyond doubt the true source of the drug, and has given us a full botanical description and figure of the plant in question, *Euphorbia resinifera*, Berg. It grows in Morocco, among the Atlas Mountains, and was well known to the ancients, as both Dioscorides and Pliny gave accounts of the collection of the resin on Mt. Atlas, and made notes of its extremely acrid properties (*Pharmacographia*). The drug is collected by making incisions into the stems, from which the milky fluid exudes and concretes on exposure to the air, incrusting the surface and particularly the spines in its downward flow. Finally, toward the latter part of the summer, it is gathered by the collectors, who are compelled to protect themselves from its irritating, acrid dust, by enveloping the mouth and nostrils with a cloth (see *Euphorbia corollata* for further history).

Description.—In commerce euphorbium is found in irregular, yellowish, or brownish, slightly friable tears, of a wax-like appearance, often perforated with 1 or 2 holes, united at the base, and usually mixed with the prickles of the plant and other impurities. They have hardly any odor, and that slightly aromatic, and a feeble taste, succeeded by considerable heat and persistent acrimony. Euphorbium is partially dissolved by water, forming a milk-like fluid when rubbed up with it; its best solvents are alcohol, ether, and oil of turpentine. Euphorbium must be powdered with great caution, as it excites violent sneezing, and even inflammation of the eyes. Thrown on the fire, euphorbium melts, swells, and burns with a pale flame, evolving an odor-like that of benzoic acid.

Chemical Composition.—Euphorbium, according to Henke (*Archiv. der Pharm.*, 1886, p. 729), consists of resin soluble in ether (26.95 per cent), resin insoluble in ether (14.25), *euphorbon* (34.6) *caoutchouc* (1.1), malic acid (1.5), gum, salts (20.40), and ammonia-soluble matters (1.2). The intense acidity of the drug is due to the ether-soluble *resin*, which melts at from 42° to 43° C. (107.6° to 109.4° F.). The resin insoluble in ether melts between 119° and 120° C. (246.4° and 248° F.). *Euphorbon* ($C_{15}H_{22}O$, Flückiger; $C_{15}H_{22}O$, Hesse; $C_{15}H_{22}O$, Henke), was first obtained in an impure state by Dragendorff and Alberti, in 1864, and was four years later given its name and prepared pure by Flückiger (*Wittstein's Vierteljahresschrift*, 1868, p. 89). It is a crystallizable substance, fusing at 68° C. (154.4° F.), (Henke), and yields upon treatment with phosphorus pentoxide, certain hydrocarbons, as *heptane* (C_7H_{16}), *octane* (C_8H_{18}), and *paraxylene* ($C_6H_4[CH_3]_2$).

It is soluble in ether, benzin, benzene, chloroform, amyl alcohol, and alcohol, and glacial acetic acid; almost insoluble in hot water, and precipitated by tannic acid. Henke prepared it by extracting the gum with petroleum and purifying the crystalline *euphorbone* thus obtained by dissolving it in alcohol and adding alcohol to permanent turbidity, allowing the yellow resin to evaporate, and then evaporating the clear liquid and crystallizing from benzin. It is tasteless, neutral reaction, dextro-rotatory, and is not affected by diluted acids nor by alkalis. A bitter principle is also present, and may easily be obtained by boiling an alcoholic extract of the gum with water. This dissolves the bitter principle, leaving with some of the acrid resin. The existence of Buchheim's bitter *euphorbin* obtained (1875), by evaporating the acrid resin with alcoholic caustic potash and precipitating with a diluted acid, is doubted by Flückiger and Henke (*Pharmacognosie*, 1891).

Action, Medical Uses, and Dosage.—Emetic, cathartic, and irritant. It is, however, used for these properties, on account of its severity of action. Its principal use is externally as a rubefacient or vesicant. The following tincture forms an excellent counter-irritant: Take of powdered euphorbium 1 ounce, coarsely powdered cantharides and mezereon bark, of each, 2 drachms, spirits of wine 2½ fluid ounces. Mix together, digest for 8 days, then filter, and to the filtered tincture add, white colophony 1 ounce, white wax 6 drachms. With this preparation, paper or silk may be coated three times, by means of a soft sponge, and, when dry, forms an excellent plaster for *rheumatic, gouty, and neuralgic pains*. Powdered euphorbium is frequently added to the compound tar plaster to render it more active.

Related Species.—*HURA*, *Sand-bar tree*. Two species of *Hura*, the *Hura* Willdenow, and *Hura crepitans*, Linné, both of the *Nat. Ord.*—Euphorbiaceæ. The latter is indigenous to Central and South America, and to the West Indies, known as *ajupar*. The seed capsules break with violence, scattering the seeds. It is used in Mexico under the name *habilla* or *pepila de San Ignacio*, as a drastic cathartic. The leaves, after being prepared in oil, are applied to the skin. An acrid, milky juice is obtained from the tree. This juice, as well as the bark, is emeto-cathartic, acting somewhat like the euphorbiaceous plants in general. *Hura brasiliensis* is known in South America as *amucou* or *usacu*. It differs from the former in having oblong, in place of ovate catkins. The bark *casca de amucou*, like to the first, is acrid. The acrid principle of *Hura* has been named *hurin*. It is a crystalline substance obtained by precipitating with water an alcoholic extract of the evaporated milky juice, dissolving the resinous matter in ether. When heated it volatilizes in acid vapors, and malates are likewise present. The seed integuments contain tannin, gallic acid, and other substances, while the kernel yields albumen, solid fatty matter, salts, and a fixed oil, which alcohol dissolves. The Brazilians use it as a remedy for elephantiasis. Even the decoction may vesicate. It is powerfully irritant to the gastro-intestinal mucous membrane, producing violent emeto-cathartic effects. It is probably ineffectual, though mitigates the disease, but not a cure, is reported from its use.

MANCHINEEL.—The *Hippomane Mancinella*, Linné, a West Indian tree possesses similar properties. Its fruit, resembling in color and size our common apple, is said to be poisonous when placed in the water. The tree abounds in acrid, milky juice, the poisonous principle of which is volatile. Fat, resin, caoutchouc, volatile oil, gummy material, and other substances are, according to Ricord-Madianna, constituents of manchineel. The juice of the tree is irritating, causing vesication, and if in contact with the conjunctiva, producing a severe conjunctivitis. The Indians poison arrows with it; even sleeping underneath the tree produce swelling of the body. Both the juice and the fruit produce inflammation of the intestinal symptoms, with emeto-catharsis.

EUPHORBIA COROLLATA.—LARGE FLOWERING SPURGE

The bark of the root of *Euphorbia corollata*, Linné.

Nat. Ord.—Euphorbiaceæ.

COMMON NAMES: *Large flowering spurge, Blooming spurge, Milk parley, Milk,* etc. (see *History*).

ILLUSTRATION: Meehan's *Native Flowers*, Vol. I, p. 109.

Botanical Source.—This plant has many common names, and in sections is improperly called *Roman's root*. It is a perennial plant, with a slender, erect stem, 1 or 2 feet high, generally simple and smooth. The leaves are yellowish, large and branching. The leaves are scattered, sessile, oblong-

linear, entire, flat or revolute at the margin, smooth in some plants, very hairy in others, verticillate and opposite in the umbel, and from 1 to 2 inches in length. The flowers are in large, terminal umbels, with a corolla-like involucre, which is large, white, and showy. The umbels are 5-rayed, supported by as many bracteal leaves; not infrequently a small axillary branch or two arises from the sides of the stem below the umbel. The rays of the umbels are repeatedly trifid or dichotomous, each fork attended by 2 leaflets and a flower. The involucre is large, rotate, white, with 5 obtuse, petal-like segments; at the base of these divisions are 5 interior, very small, obtuse segments. Stamens 12; a great portion of the plants are wholly stamiferous. The fruit is a smooth, 3-lobed, 3-celled capsule; the cells are 1-seeded, and the seeds smooth (L.—W.).

History.—Though not extensively used in medicine, many of the Euphorbias are consumed in the Eclectic practice. That some of them are excellent remedies, and could well take the place of some other extensively used drugs, there can be no doubt. The *Euphorbia Ipecacuanha* and *Euphorbia corollata* are old Eclectic drugs, while the *E. hypericifolia* was reintroduced, in 1874, by Dr. H. L. True (*Eclectic Medical Journal*, 1874), having been previously mentioned in the *American Dispensatory*. Though but little used, these drugs have staggered under a load of popular appellatives, some of them being peculiar to each plant named, others being shared by plants bearing no relation to the Euphorbias. *Euphorbia Ipecacuanha* is called *wild ipecac* and *ipecacuanha spurge*; *E. corollata*—*blooming spurge*, *large flowering spurge*, *milkweed*, *snake's milk*, *hippo*, *picac*, *purge root*, *milk purslane*, *emetic root*, *apple root*, *Indian physic*, *ipecac*, *ipecacuanha* and *Bowman's root*; *E. hypericifolia*—*large spotted spurge*, *garden spurge*, *black purslane*, *milk purslane*, *eye bright*, and *flaxweed*; *E. pilulifera*—*pili-bearing spurge*, *asthma-weed* and *snake-weed*. In view of this mass of confusing popular names, the physician will recognize the necessity of adhering to the botanical appellations for these plants.

There are many other species of Euphorbia, though all possess widely diverse characteristics from those of our medicinal plants. In the dominions of the Mauritanian despot the plants abound as large succulent trees or bushes resembling cacti, but differing from them in having a milky juice, which exudes on the slightest puncture. Nearly all the Euphorbias are more or less poisonous, and all exude this acrid milky fluid when broken. Like their fellow of the same natural order, the *Ricinus communis*, or *Castor oil plant*, most of them have cathartic powers, though some are astringent. An ornamental species, originally from Mexico, whose floral bracts are often 4 or 5 inches long and of a bright vermilion color, is familiar to flower lovers as "*fire on the mountain*, *painted leaf*, *Mexican fire plant*, or *poinsetta*" (*E. heterophylla*). In Africa *gum euphorbium* is gathered from the *E. resinifera*. Incisions are made into the stems from which the juices flow freely. From its acidity great care must be exercised by the gatherer, as it produces a violent rhinitis. A species (*E. Tirucalli*) is in common use around Madras for hedging purposes. The leaves, which are used as vesicants, will not be partaken of by cattle. *E. Lathyris* was ordered by Charlemagne to be cultivated in all monastic gardens on account of the value of its purgative seeds. Two species, the *E. hybernica* and *E. piscatoria*, will stupefy fish, a small quantity serving to render the waters of a river poisonous to fish for a long distance down the stream. Though poisonous in the raw state, the *E. edulis* and *E. balsamifera* when boiled, may be eaten as pot-herbs, and the *E. Cattimundoo* furnishes a caoutchouc. In hot countries the milk of a certain species is employed as a caustic, while another furnishes the natives with an "arrow poison" by simply dipping the weapon in the milky juice. Anthelmintic properties are possessed by the *Euphorbia thymifolia*, Linné, of India.

The scientific name *Euphorbia* is said to have been given to this genus of plants by a celebrated African monarch, King Juba of Mauritiana. This king was the son of the partisan Juba, of the wars of Pompey and Cæsar. It is claimed that he was exceptionally learned and had some knowledge of botany and medicine. Having found purging properties in a plant growing in his dominion, he called the attention of his renowned court physician, Euphorbus, to it and named it in his honor—*Euphorbia*. The trivial name, *spurge*, seems to have arisen from the reputed property given by King Juba, as it is but a contraction of "*espurge*," a French term meaning to purge.

One of our early botanists, Nuttall, had a peculiar dislike to the Euphorbia and could see no good in them, regarding them as dangerous and needful remedies. Rafinesque, who was more nearly Eclectic than any other of the botanists, and whose views were those generally accepted by the Eclectics, says of the *E. corollata* that it is a safer and better emetic than common, from the fact that its action may be regulated according to the quantity which, as we all know, can not be done with the latter drug. This action is particularly noticeable in fluid preparations of ipecac. Rafinesque notes the singular similarity of the Louisiana Indian name "*peha*" and Brazilian "*ipeca*," both meaning "*emetic root*." Barton considered the *E. corollata* of equal value to ipecac, besides possessing the advantage of having no taste and odor.

Euphorbia corollata is found in dry fields and woods throughout Pennsylvania, Canada and the United States, flowering from June to September. The juice, which exudes freely from all parts of the plant when bruised, is irritating to the cutaneous structures, and, if kept in contact sufficiently long, will cause pustulation and even vesication. The root, or part used, when dried is odorless and nearly tasteless.

Description and Chemical Composition.—The root is from $\frac{1}{2}$ of an inch to 1 or 2 inches in diameter, 1 or 2 feet in length, odorless, and nearly tasteless, producing a pungency in the mouth and fauces after having been chewed for some time. It should be gathered in the fall. The bark of the root is the medicinal part. It is from $\frac{1}{4}$ to $1\frac{1}{2}$ inch in thickness, constituting the major part of the root, and imparts its properties to alcohol or water. It forms a light, brownish powder, speckled throughout with innumerable fine dark spots, somewhat resembling a mixture of fine pepper and salt, with the exception of color. Dr. Koffer found it to contain resin, mucilage, and caoutchouc. It is possible, but not probable, that *euphorbon* is present, as it has been found in the *E. peruviana*. Kino and catechu are incompatible with this plant; when united with either, the medicinal powers of the Euphorbia are destroyed, while the astringent powers of kino or catechu becomes entirely altered. Probably all vegetable astringents are incompatible with the agent under consideration. Opium interferes with the emetic operation, and should not, therefore, be given in combination with it when emesis is desired. Acetic acid also interrupts its emetic influence, and it to pass off by the bowels (*Amer. Jour. Pharm.*, Vol. V, p. 166).

Action, Medical Uses, and Dosage.—Euphorbia is emetic, diaphoretic, expectorant, and epispastic. Small doses are expectorant and diaphoretic; larger doses produce emesis usually without much pain or spasm, nausea or griping. Overdoses will produce dangerous hyperemesis, or hypercatharsis, or both, and not infrequently give rise to an unpleasant inflammatory state of the alimentary canal. A dose that falls short of emesis usually proves cathartic.

Fifteen or 20 grains of the powdered bark of the root will excite emesis. Four grains of the powdered root bark, given every 3 hours, will act as a cathartic; or the compound powder of ipecacuanha and opium may be employed for the same purpose, substituting the *E. corollata* for the ipecacuanha. In doses of 3 grains, exhibited occasionally in a little honey, syrup or molasses, it operates as a useful expectorant, and may be administered in all cases where such action is desired. Even when given in large doses, it is apt to induce inflammation of the mucous coat of the stomach and bowels, with hypercatharsis. Occasionally, when given as an emetic or cathartic, it causes distressing nausea, with considerable prostration. From 4 to 10 or 12 grains generally act as a cathartic.

The principal use to which this drug was put by the early Eclectics was as an emetic or emeto-cathartic in *drospical conditions*, but undoubtedly were better agents in this class of affections in digitalis and the apocynums. An emetic dose was given 2 or 3 times a week for *hydrothorax* and *ascites*. As an emetic it should never be employed where there is great debility or when an inflammation of the digestive organs is present. It has been employed with success in *catarrhs*. It has a direct action on mucous surfaces, and, when given in small doses is valuable to check inflammatory action of the stomach and bowels; it relieves irritation, promotes digestion, and increases functional activity; it rectifies irregularity of the bowels and rarely fails to overcome constipation.

as indicated. It is often indicated in *diarrhœa* and *dysentery*, especially the so-called bilious forms. *Chronic bronchitis* and *laryngitis*, with profuse mucous discharges, have been cured by it. Prof. King used it in several cases of *partial deafness* with tinnitus from extension of *chronic catarrhal inflammation of the nares and throat* to the Eustachian tubes. It is also indicated (in small doses) in *catarrhal inflammations* with abundant mucous discharges, and especially if the patient be debilitated. For this purpose it has served a good use in *vesical catarrh*.

Dose of the powder as an emetic, 15 to 30 grains, every 15 minutes; tincture (emetic), 15 to 60 drops, every 15 minutes; for specific uses, tincture, fraction of a drop to 10 drops; specific euphorbia, $\frac{1}{10}$ to 10 drops.

Specific Indications and Uses.—Indications for both this drug and for *E. Ipecacuanha* are long-continued gastric irritation, irritative diarrhœa, dropsy with irritation of mucous tissues, and catarrhal discharges with debility. Tongue elongated and pointed with prominent papillæ, uneasy sensation in the stomach; cholera infantum with hot and tender abdomen, constant desire to defecate, with greenish irritating stools.

EUPHORBIA HYPERICIFOLIA.—LARGE SPOTTED SPURGE.

The entire plant *Euphorbia hypericifolia*, Linné.

Nat. Ord.—Euphorbiaceæ.

COMMON NAMES: *Large spotted spurge*, *Garden spurge*, *Black purslane*, *Milk purslane*, *Eye-bright*, *Flux-weed*.

Botanical Source and History.—*Euphorbia hypericifolia* is a common weed, found in gardens and on cultivated land, in all parts of the United States. The stem is from 1 to 2 feet in length, ascending, and much branched; it is smooth, and when the plant grows in sunny situations, is of a purple color. The branches are alternate, and proceed from opposite sides of the stem, giving the plant a flat appearance. The leaves are about an inch long, opposite, unequal at the base, and supported on very short leaf-stalks; they are oblong, obtuse, triple-veined from the base and serrulate, with numerous small, appressed teeth. The larger leaves have large purple spots near the center, which is very characteristic of the plant. The flowers are small, inconspicuous, and appear late in summer. They have the peculiar structure of the genus *Euphorbia*, and the involucrate clusters are borne from the forks of the branches on slender stalks about $\frac{1}{2}$ inch long. The fruit is a 3-lobed carpel, containing 3 wrinkled, blackish seeds. The plant is minutely described in earlier editions of this *Dispensatory*, as follows: "This plant, also known by the names of *Black purslane*, *Milk purslane*, *Eye-bright*, etc., is an annual plant, with a smooth, somewhat procumbent, branching stem, from 1 to 2 feet high; branches dichotomous, divaricate-spreading. Leaves from $\frac{1}{2}$ to 1 inch in length, about one-fourth as wide, opposite, oblong, somewhat falciform, serrated, oblique or heart-shaped at base, often curved, 3 to 5-ribbed underneath, on very short petioles, often marked with purple oblong dots and blotches. Flowers small, white, numerous, disposed in terminal and axillary corymbs. Fruit mostly rather hairy; seeds 4-angled, obscurely wrinkled transversely" (W.—G.).

History and Chemical Composition.—*Euphorbia hypericifolia* is an indigenous plant, growing in rich soil in waste and cultivated places, as old cornfields, but seldom in woods, and flowering from July to September. The whole plant is used, and yields its properties to water or alcohol; the leaves have a sweetish taste, succeeded by a sensation of harshness and roughness. The plant contains caoutchouc, resin, tannin, gallic acid, etc. (Wm. Zollickoffer, 1833). No further analysis or chemical examination seems to have been made. Dr. H. L. True brought this drug forward in the *Eclectic Medical Journal*, 1874, since which time numerous articles have appeared in various medical journals, and at present the plant is in regular use among Eclectic physicians, having obtained a reputation in the treatment of bowel disorders.

Action, Medical Uses, and Dosage.—Garden spurge acts principally upon the digestive tract and the sympathetic nervous system. Dr. True, its introducer, proved the remedy upon himself, using an infusion of leaves and tops (3ss to water Oj). He took $1\frac{1}{2}$ pints of the infusion at one dose. Shortly afterward, he experienced a fullness in the frontal and parietal regions, followed by a headache

similar to that produced by *macrotia*, but less severe. The pain then centered at the top of the head and a characteristic heat was felt over the eyes. The pain could not be fixed upon anything but the headache. There was no tinnitus, vertigo, nor was sleep produced, though a feeling of drowsiness and languor attended the active stage. The maximum effect of the drug was produced in 2 hours and subsided in 3½ hours. An unpleasant fullness with oppression at the epigastrium accompanied the head symptoms. The drug proved so costly that he was obliged to take physic the following day. He concluded that the doses it acted primarily as a cerebral stimulant, and secondarily as a sedative to the brain and sympathetic nervous system. In no sense could it be called a cathartic. Dr. True found this drug to be very efficient as an injection for use in several cases, some of them chronic, with complete success. Its principal use, however, for which the drug was brought out, was for *gastro-intestinal disorders*. It is one of the most certain remedies for *cholera infantum*, having been employed where *ipsecac* proved useless. *Typhilitis*, *mucro-enteritis*, *dysentery*, *irritant diarrhoea* are also cured by it when its indications are present. These are gastric irritation, or irritation of any portion of the mucous lining of the intestines. It is usually employed with specific aconite. It has been of service in *menorrhagia* and *leucorrhoea*, both from debility, and is recommended for *infantile pneumonia* and *bronchitis*. It is also valuable in *summer colic* in *adults*. Excellent results have attended its employment in *cholera morbus*. Its most marked property is that of removing gastro-intestinal irritation. The dose of the strong infusion of the plant (3ss to boiling water Oj, infused 4 hours) for a child, from 15 minims to 2 fluid drachms every hour; for an adult, a teaspoonful to a tablespoonful every hour. Dose of specific spotted spurge, 1 drop in water every 1 or 2 hours.

Specific Indications and Uses.—Gastro-intestinal irritation; *cholera morbus*; *mucro-enteritis*; *dysentery*; vertigo, with constipation; "diarrhoea, the discharges being greenish and irritant; frequent desire to go to stool, which is sometimes without any motion" (Scudder).

Related Species.—*Euphorbia maculata*, Linné, or *Spotted spurge*, is possessed of similar properties, and has been used with advantage in the same forms of disease, *cholera morbus*, *diarrhoea*, *dysentery*, etc. It is an annual plant, generally found growing with the *E. hypericifolia*. It possesses sensible properties analogous to those of this variety. It has a procumbent, spreading flat on the ground, much branched, and hairy; leaves opposite, oval or oblong, serrulate toward the end, unequal at the base, slightly 3-ribbed, smooth above and pale beneath, oblique at base, on short petioles, often spotted with dark-purple. The lines long, one-half as wide. Flowers white, solitary, axillary, much shorter than the leaves, appearing from July to October; female flowers naked. Filaments articulated; perianth squamose; capsule 3-grained, smooth, pubescent, or warty; seeds 4-angled, obscurely transversed, about one-third smaller than the *E. hypericifolia* (W.—G.). Zollicoffer found resin, caoutchouc, and gallic and tannic acids in this species.

Euphorbia prostrata, Aiton, *Swallowwort*, a plant growing in the southwestern part of the United States and Mexico, is one of the many so-called specifics against the rattlesnake, and other poisonous reptiles, spiders, etc. It is known to the natives of New Mexico as *gollindrinera*. The fresh juice of the plant is procured by bruising it in a mortar, adding water and expressing it; the dose is 3 or 4 fluid ounces, repeated every 1, 2, or 3 or oftener, according to the urgency of the case; the bruised plant being at the same time applied to the wound. The plant grows in dry, hard, sandy soils, has long, thread-like stems, resembling somewhat the *Coptis trifolia*, and which become entangled with the leaves opposite, dark-green, obcordate, petaloid, from ½ to ¾ inch long; flowers April to November, are small, white, axillary, dark-purple at the orifice of the corolla; sepals 4; petals 4; root large, deep-brown. The whole plant contains an abundant odorless, insipid, milky juice.

Euphorbia humistrata, Engelm. —Mississippi valley. Resembles the preceding.

Euphorbia chilensis, of Chili.—Is employed as a drastic cathartic.

Euphorbia ocellata, Dur. and Hilg.—Pacific states. Contains gallo-tannic acid and is used to antidote snakebites.

Euphorbia lata, Engelm. —United States. Cases of poisoning by seeds, reported at Philadelphia, by Harlan, producing serious gastro-intestinal disturbance, with extreme catharsis, followed by dilatation of pupils and stupor (*Med. and Phys. Researches*, p. 66).

Euphorbia Lathyris, Linné (*Tithymalus Lathyris*, Scopoli); *Caper* or *Garden spurge*.—A native of the south of Europe, but cultivated and somewhat naturalized in the United States. It has been introduced into New Mexico and western Texas (Coultter). The seeds, which are merely used under the name of *semen cataputiae minoris*, yield an expressed oil which is irritative, and deposits a crystalline mass upon standing. O. Zander obtained 42 per cent by extraction with carbon disulphide (*Amer. Jour. Pharm.*, 1878, p. 339). *Esculin* (Linné)

is also one of its constituents (R. Tawara, *Chem. Ztg.*, 1889, p. 1706). Five seeds have been known to purge, and also to provoke emesis. It is said to act somewhat like croton oil. In doses of 5 to 10 drops the pure oil is said to act mildly, but is liable to assume dangerous acrid properties. When recent the oil is without odor, colorless, and practically tasteless. Cases of poisoning by the seeds have been reported (*Bull. de Therap.*, Vol. CI, p. 541). The antidotes are opiates. The milky juice from this plant, collected in autumn, revealed under the microscope the presence of *euphorbon*, starch, and crystals of calcium malate (Henke, *Archiv. der Pharm.*, 1886, p. 753).

Euphorbia cremocarpus.—Pacific states. Contains resin, an acid, and a volatile oil. Used to stupefy fish to facilitate their capture (*Proc. Cal. Coll. Pharm.*, 1885).

Euphorbia Drummondii, Boissier.—Australia. This plant, according to Bailey and Gordon, is poisonous to sheep. It is also fatal to cattle. If eaten by them early in the morning, before the sun has dried the plant, the result is said to be nearly always fatal. Sheep will only eat it when grass is scarce. The head becomes enormously swollen, and the animal, being unable to support it, is forced to drag it over the ground. The ears also swell, and suppuration ensues. It is known to the natives as *caustic creeper*, *milk plant*, and *pox plant*. The *Euphorbia alsingflora*, Baillon, is likewise poisonous to sheep (*Useful Native Plants of Australia*, Maiden). Dr. J. Reid (*Austral. Med. Gaz.*, No. 61), is said to have isolated a crystalline alkaloid devoid of color from *E. Drummondii*, and named it *drummine*. He ascribes to it anæsthetic properties, which property is considered by some as doubtful (see also *Amer. Jour. Pharm.*, 1887, p. 264). The entire subject of its chemistry needs verification.

Euphorbia heterodoxa, Mueller.—Brazil. This plant is known as *Ateloz*, *Arelaz*, and *Arveloz*. The juice is said to act somewhat like jequirity. When fresh it produces dermatitis, and destroys diseased tissue without producing marked pain. Spread upon a granulating sore, it produces a profusion of pus, and placed upon morbid growths destroys them, layer after layer, and induces granulation. The acrid principle seems to reside in a resin. It has been used with reputed success in the treatment of *cancerous growths* and *symphilitic chancreoids*.

Euphorbia helioscopia, Linné.—Texas and other parts of the United States. The juice of this plant is said to remove *warty growths*.

Euphorbia marginata, Pursh; *Snow-on-the-mountain*.—Cultivated in gardens in the United States. Produces effects like those of poison-oak (*Bot. Gaz.*, 1890, p. 276).

MANZANILLO.—A West Indian Euphorbiaceæ, the juice of which is violently irritant, and when internally administered (20 drops), produced a fatal gastro-intestinal inflammation. It is diuretic, and in 2-drop doses is reputed actively purgative. The Cubans make use of it in *tetanus*.

Mercurialis annua (Nat. Ord.—Euphorbiaceæ). Europe. Reichardt, in 1863, obtained from this herbaceous plant a volatile base, *mercurealine*, which he describes as an oily base, analogous to *conine*, of strongly alkaline reaction, possessing a penetrating, narcotic odor, and resinifying when exposed to the air. It begins to distill at 140° C. (284° F.). E. Schmidt (1878), declares it identical in every respect with *monomethylamine* (CH_3NH_2), and to be associated in the plant with small amounts of *trimethylamine*. When boiled the plant is rendered non-acrid, and is used as a poultice. It was formerly regarded an important remedy in Europe, where it was variously lauded as a purgative, diuretic, emmenagogue, and antisymphilitic. A related European species, *Mercurialis perennis*, is likewise toxic.

EUPHORBIA IPECACUANHA.—AMERICAN IPECAC.

The bark of the root of *Euphorbia Ipecacuanha*, Linné (*Euphorbia gracilis*, Elliott).

Nat. Ord.—Euphorbiaceæ.

COMMON NAMES: *Wild ipecac*, *American ipecacuanha*, *Ipecac spurge*, *Carolina ipecac*, *White ipecac*, *Spurge*, etc.

Botanical Source.—This is a perennial plant, with a yellowish, irregular, fleshy root, very large in proportion to the plant it bears, running deep into the sand, sometimes extending to the depth of 6 feet. The stems from one root are numerous, suberect or procumbent, smooth, thick, succulent, regular dichotomous, jointed at the forks, forming large branches on the surface of the ground, and from 3 to 12 inches long. The leaves are inserted at the joints, opposite, 1 or 2 inches long, by $\frac{1}{2}$ or $\frac{3}{4}$ an inch wide, sessile, smooth, varying from oblong and circular to linear, and, in color from green to purplish. The flowers are solitary, on long peduncles from the forks of the stem, and small. Calyx spreading, with 5 exterior obtuse segments, with 5 small, gibbous, inner segments or nectaries. The stamens are numerous, in 5 parcels, appearing at different times 2 or 3 together, with double anthers. The fertile flowers have a large, roundish,

FIG. 110.

Euphorbia Ipecacuanha.

drooping, pediceled germ, crowned with 6 revolute stigmas. The capsule is 3-celled, containing 3 white, areolate-pitted seeds (L.—W.—G.).

History and Description.—This is an indigenous plant, found growing in dry, sandy soils, on Long Island, in New Jersey, and the middle and southern states, and flowering from May to August. As with the *E. corollata*, it yields a milky juice, which causes a pustular eruption when applied to the skin. The root is the part used in medicine. The fresh root is from 3 to 7 feet long, tuberculated, and of a yellowish color; from $\frac{1}{4}$ to 1 inch in diameter, and of a very acrid taste. The dry root is light and brittle, without odor, and has a sweetish, not very disagreeable taste (E. & V.). The powdered root is of a light-brown, or light snuff-color, speckled similar to *E. corollata*. Water or alcohol takes up its active properties. Its incompatibles are probably the same as those of the *E. corollata*.

Chemical Composition.—Analysis of this plant by C. Petzelt, in 1873 (*Amer. Jour. Pharm.*, p. 255), revealed the presence of resin, gum, glucose, starch in abundance, fixed oil, calcium sulphate, and other salts. The resin is dark in color, has at first a bitter taste, which subsequently becomes pungent and nauseating. This resin he believed to carry the active emeto-cathartic properties of the root. Small doses ($\frac{1}{2}$ grain) acted as a hydragogue cathartic, while larger doses ($1\frac{1}{2}$ to 2 grains) induced nausea and emesis. It is insoluble in benzin and ether, but dissolves in alcohol. The root is believed to contain a glucosid from the fact that the reaction for glucose is not apparent unless the root be first boiled with a diluted acid (Dilg, *Amer. Jour. Pharm.*, 1876, p. 485). Benzin extracts from the root, among other substances, *euphorbon* (see *Euphorbium*).

Action, Medical Uses, and Dosage.—It very much resembles the *E. corollata* in its action upon the system, but is less energetic. It may be employed as a substitute for it or for ipecac. It is emetic, diaphoretic, expectorant, and epispastic; and may be used in the same doses and for the same purposes as the *E. corollata*; in *dropsical affections* it is preferred by some practitioners. When given in cathartic doses, say from 3 to 10 grains, it is said to promote the menstrual discharge. As an emetic and cathartic, it has been found valuable in *bilious colic*, but is superseded in this disease by the *Dioscorea villosa*, which acts promptly and efficiently without any unpleasant symptoms. In *dyspepsia*, 1 or 2 grains, repeated 3 times daily, will be found useful. The dose of the powdered root is from 10 to 15 grains as a hydragogue; 1 to 3 grains as an expectorant and diaphoretic. It is occasionally used in *jaundice* and *obstinate torpidity of the liver*. It was formerly principally used by physicians as a hydragogue in *dropsical affections*; but, in recent years, it has been used to allay *gastro-intestinal irritation* and *inflammatory action*, as in some forms of *dysentery* and *diarrhœa*.

Specific Indications and Uses.—(Same as for *E. corollata*, which see).

EUPHORBIA PILULIFERA.—PILL-BEARING SPURGE.

The entire plant *Euphorbia pilulifera*, Linné.

Nat. Ord.—Euphorbiacæ.

COMMON NAMES: *Pill-bearing spurge*, *Snake-weed*, *Cat's-hair*, *Queensland asthma-weed*, *Flowery-headed spurge*.

Botanical Source.—A prostrate or ascending (erect, Coulter), pubescent, herbaceous annual, having a stem which forks at the base, bearing oblique, oblong-ovate leaves, opposite, serrate, and acute at both ends. The flower-heads, which are cymose, minute, numerous, and crowded, are borne on a stalk which proceeds from only one leaf-axil. The involucre is minute and arranged in dense, short-stalked clusters, which are terminal. The gland-appendages are narrow or obsolete. The fruit is an acute-angled, hairy pod, inclosing the reddish 4-angled, transversely rugulose seeds.

History and Chemical Composition.—This plant is found in most tropical and subtropical regions. In the United States it grows throughout the gulf states to Texas and New Mexico (Coulter). This plant reaches a height of 10 to 15 inches, and has a red, fibrous root. The stalk, which is reddish, is covered with peculiar yellowish hairs. It grows well in almost any soil, and, in some countries,

is a wayside weed and difficult of extermination. In Australia, where it is abundant, it is much esteemed by the laity as a remedy for coughs, colds, and bronchial and pulmonary disorders in general, including asthma. Its decoction gives an acid reaction with litmus paper. Chas. G. Levison, of San Francisco, who made a quantitative analysis of the plant (*Amer. Jour. Pharm.*, 1885, p. 147), found, among other substances, a trace of tannin, volatile substances, a non-volatile wax, salts of potassium, magnesium, sodium, and silica, starch, and several resins of a glucosidal character, differing mainly in the strength of alcohol required to accomplish their solution. *Euphorbia pilulifera* was introduced to the medical profession by Parke, Davis & Co., of Detroit, through whose extensive advertising it became generally known.

Action, Medical Uses, and Dosage.—*Euphorbia pilulifera* is one of the tropical spurge. Its physiological effects are not pronounced, except that it is irritant to the gastro-intestinal tract, and may occasion epigastric distress with nausea. Upon other portions of the mucous surfaces and the skin it seems to be inactive. Its action is said to be confined chiefly, if not wholly, to the respiratory and cardiac centers, and elimination takes place by the liver. It is brought forward as a reliable anti-asthmatic, being particularly adapted to spasmodic forms of asthma. *Dyspnoea of cardiac disease* has been relieved by it. It is recommended for *chronic bronchitis* in old people. It promoted expectoration, allayed cough, and exerted an anodyne influence in a case of *pulmonary consumption*. It has likewise given good results in *emphysema*. Dose of ordinary tincture, from 10 to 60 drops, as an anti-asthmatic, for which purpose it is highly valued in Australia. The leaves may be smoked in a pipe for *paroxysmal asthma*. Infusion (3ss to aqua Oj), $\frac{1}{2}$ to $\frac{1}{4}$ fluid ounce; fluid extract, 10 to 30 drops; specific asthma-weed, $\frac{1}{10}$ to 30 drops.

Specific Indications and Uses.—Spasmodic action of respiratory muscles, with bronchial irritation.

Related Species.—*Euphorbia partiflora*. This species is mentioned merely on account of its having been used to adulterate, or as a substitute for, the above species, which it closely resembles. Its points of difference are: Less flowers in the flower-heads, minutely papillose, obtuse seeds, and by having upon the involucre glands a white appendage, of an obovate-orbicular shape.

EUPHRASIA.—EYEBRIGHT.

The plant *Euphrasia officinalis*, Linné.

Nat. Ord.—Scrophulariaceæ.

COMMON NAME: *Eyebright*.

Botanical Source.—This is an elegant little annual plant, with a square, downy, leafy stem, simple or branched, and from 1 to 5 inches in height. The leaves are almost entirely opposite, ovate or cordate, downy, strongly ribbed and furrowed, the lowest crenate, and the floral with sharp, tooth-like serratures. The flowers are axillary, solitary, very abundant, and inodorous, with a brilliant variety of colors. The corolla varies much in size as well as in color, being commonly white, with deep purple streaks, and a yellowish palate. The upper lip of the corolla is galeate, emarginate, having 2 broad, spreading lobes; the lower lip is larger, spreading, 3-cleft, and the lobes are obtuse or notched. The calyx is campanulate and 4-cleft. Stamens 4, fertile under the upper lip; anthers violet, lower cells of the upper ones with a long spur. Pod oblong and flattened. The seeds are numerous, oblong, and grooved lengthwise (L.—G.).

History and Chemical Composition.—This is a small plant, indigenous to Europe and this country, bearing white or red flowers in July. The recent leaves are commonly employed; they are inodorous, but of a bitter, astringent taste. Water extracts their virtues. Enz (1859) examined the recent plant. He found

Euphorbia pilulifera.

it to contain mannit, grape sugar, volatile oil in small amount, and principle, cellulose, and other plant constituents, besides a number of organic character, and tannin, the latter giving a deep-green coloration to compounds, and a bright light-green reaction with the salts of lead.

Action, Medical Uses, and Dosage.—Slightly tonic and astringent with much benefit in the form of infusion or poultice, in *catarrhal* of also of service in all mucous diseases attended with increased discharge, cough, hoarseness, earache, and headache, which have supervened in *catarrh*. It appears to specifically influence the nasal membranes and lachrymal. In *acute catarrh (fluent coryza)*, in which there is a profuse watery flow, it has most specific action. It will not only be found of great utility to counteract catarrhal phases of the parts during or following an attack of, but will tend to avert unpleasant after-effects, as *catarrhal conjunctivitis*, *catarrh*, *catarrhal deafness*, etc. *Catarrhal diseases of the intestinal tract* may be treated with euphrasia. Four fluid ounces of the infusion taken every morning on empty stomach, and also every night at bedtime is asserted to have been successful in curing *epilepsy*. Such extravagant statements are not calculated to inspire confidence in the use of medicines. Dose of specific euphrasia drops; the infusion (3i to aqua Oj), 2 fluid drachms to 4 fluid ounces.

Specific Indications and Uses.—Acute catarrhal diseases of the eyes and ears; fluent coryza with copious discharge of watery mucus. "Extraction of acrid mucus from eyes and nose with heat and pain in frontal sinus" (S...).

EXTRACTA ET EXTRACTA FLUIDA.—EXTRACTS AND FLUID EXTRACTS.

Fluid and Solid Extracts.—Formerly these preparations were separated into two classes and were considered in different sections of the Pharmacopoeia. In the present they are arranged therein successively in alphabetical order, in the general class. We shall thus consider them, first prefacing the formula by appropriate introductory remarks.

Extracta Fluida.—**FLUID EXTRACTS.** These are concentrated alcoholic and have the advantage over solid extracts in being prepared with less evaporation, and consequently less heat, whereby their activity is not so liable to impairment. With some drugs in which the medicinal virtues depend upon a volatile fluid or evanescent substance, and can not be reduced to a solid extract or a dry condition, the fluid extract or a fluid representative, prepared by the only rational mode of drug administration. The established strength of fluid extracts preceding the U. S. P. of 1880, was 1 troy ounce of drug to 1 fluid ounce of the finished fluid extract. The present strength, with few exceptions, is 1 gramme of the drug to 1000 cubic centimeters of the finished fluid extract. The deviation from the original strength is so little as to be of no consequence taken in connection with the variation in drug quality and the personal variations of the operator and patient. For all practical purposes, there is no difference between the therapeutical values of fluid extracts made by the old and new pharmacopoeial standards. The menstruum employed in the preparation of fluid extracts varies according to the character of the energetic constituents of the plant; thus, many agents require only enough alcohol to preserve them, while those containing oils and resins require increased alcohol according to their solubility in this menstruum. Great care and attention are required in preparing these preparations, from the fact that too high a temperature or too long exposure to the action of the atmosphere frequently tends to decompose and render them worthless. One trouble relative to some of the fluid extracts is their natural tendency to subsequent decomposition; the result being the formation of precipitates that often contain valuable medicinal agents. But it does not necessarily follow that the result of decomposition is always accompanied by the formation of sediments; in many cases liquids lose their therapeutic value and remain comparatively transparent.

The terms *Essential tinctures*, *Concentrated tinctures*, and *Saturated tinctures* have been applied to preparations similar to or identical with fluid extracts.

have long since been displaced by the name fluid extract, and are practically obsolete. The *U. S. P.* contains an extensive list of fluid extracts, but not as extensive as the catalogues of medicinal manufacturers. To these formulæ we have added many others, but to give formulæ for the entire line of commercial fluids is impracticable. The Pharmacopœia contains general directions for percolation that can be easily adapted to unofficial extracts, the operator selecting the menstruum that is applicable to each drug. In addition to this, the *National Formulary* contains explicit general directions for making many unofficial fluid extracts, which general directions may appropriately be introduced before the official processes, these being given in detail by us. In our opinion, both these general methods may be improved upon, in many cases, by evading evaporation altogether. The official preparations are in accordance with the metric system, but those introduced from other sources are given in troy ounce and fluid measure.

National Formulary General Directions.—EXTRACTA FLUIDA (N. F.), *Fluid extracts.* *Formulary number, 135:* "The fluid extracts for which formulas are given in this formulary, are intended to be of the same strength as the fluid extracts of the *U. S. P.*, which directs that one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M.] of fluid extract shall be obtained from one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.] of the drug."

GENERAL PROCESSES.—"The fluid extracts of this formulary are to be prepared according to one of the following two processes, the particular one to be employed being designated in each case. These two processes are necessary because, in the preparation of some fluid extracts, two fluids are successively used, the first containing glycerin, and being in definite proportion to the drug used, while the second is free from glycerin, being intended for the exhaustion of the drug and subsequent evaporation. Accordingly, these menstrua are designated as *Menstruum I* (containing glycerin), and *Menstruum II* (containing no glycerin). As an alternative to either of these processes, a third process, dependent upon *Fractional Percolation* may be used. In this the use of heat is avoided, and it involves the use of only one kind of menstruum, even in the case of drugs for which two different menstrua (I and II) are prescribed in this formulary. In the case of the latter, a sufficient quantity of Menstruum I must be prepared to serve throughout the process."

PROCESS A. THE MENSTRUUM CONTAINS NO GLYCERIN.—"Moisten one thousand grammes (1000 Gm.) [2 lbs. av., 3 oz., 120 grs.] of the drug with a sufficient quantity of the prescribed menstruum to render it distinctly damp, and to maintain it so after several hours' maceration in a well-covered vessel. When the drug has ceased to swell, pack it in a suitable percolator, pour a sufficient quantity of the menstruum on top, and when the percolate begins to drop from the orifice, close the latter, cover the percolator, and allow the contents to macerate 24 hours. Then permit the percolation to proceed. Receive the first eight hundred and seventy-five cubic centimeters (875 Cc.) [29 fl̄, 282 M.] of the percolate separately and set it aside. Then continue the percolation with the same menstruum until the drug is practically exhausted. Evaporate this second portion—at a temperature sufficiently low to prevent the loss of any important volatile constituent—to a soft extract, and dissolve this in a sufficient quantity of menstruum so that when this is added to the reserved portion, the product will measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]. Allow the fluid extract to stand a few days, or longer if convenient, and filter, if necessary."

PROCESS B. THE MENSTRUUM CONTAINS GLYCERIN.—"Moisten one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.] of the drug with a sufficient quantity of Menstruum I to render it distinctly damp and to maintain it so after several hours' maceration in a well-covered vessel. When the drug has ceased to swell, pack it in a suitable percolator and pour the remainder of Menstruum I on top. When this has just disappeared from the surface, follow it by a sufficient quantity of Menstruum II. As soon as the percolate begins to drop from the orifice, close the latter, cover the percolator, and allow the contents to macerate during 24 hours. Then permit the percolation to proceed. Receive the first eight hundred and seventy-five cubic centimeters (875 Cc.) [29 fl̄, 282 M.] of the percolate separately and set it aside. Then continue the percolation with Menstruum II, until the drug is practically exhausted. Evaporate this second portion—at

a temperature sufficiently low to prevent the loss of any important volatile constituent—to a soft extract, and dissolve this in a sufficient quantity of Menstruum II, so that when this is added to the reserved portion, the product will measure one thousand cubic centimeters (1000 Cc.) [33 fl.℥, 391 M]. Allow the fluid extract to stand a few days, or longer, if convenient, and filter, if necessary.”

PROCESS C. FRACTIONAL PERCOLATION.—“Take of the drug, in powder of the prescribed fineness, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.], and divide it into three portions of five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.], three hundred and twenty-five grammes (325 Gm.) [11 ozs. av., 203 grs.], and one hundred and seventy-five grammes (175 Gm.) [6 ozs. av., 76 grs.], respectively. Moisten the first portion of the drug, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.] with the menstruum and percolate in the usual manner. Set aside the first one hundred and seventy-five cubic centimeters (175 Cc.) [5 fl.℥, 440 M] of percolate, and continue until fifteen hundred cubic centimeters (1500 Cc.) [50 fl.℥, 346 M] more of percolate have passed, which must be received in several portions, so that the more concentrated will be separate from the last weak percolate. Then moisten the second portion of the drug, three hundred and twenty-five grammes (325 Gm.) [11 ozs. av., 203 grs.] with the more concentrated percolates received during the preceding operation, after the first one hundred and seventy-five cubic centimeters (175 Cc.) [5 fl.℥, 440 M] have passed, and percolate again in the usual manner, using the several reserved percolates, successively, as menstrua. Set aside the first three hundred and twenty-five cubic centimeters (325 Cc.) [10 fl.℥, 475 M], and continue the percolation until six hundred and fifty cubic centimeters (650 Cc.) [21 fl.℥, 470 M] more have passed, which should also be received in several portions. Finally, moisten the third portion of the drug, one hundred and seventy-five grammes (175 Gm.) [6 ozs. av., 76 grs.] with the most concentrated of the last reserved percolates, and proceed as directed for the second portion. Collect five hundred cubic centimeters (500 Cc.) [16 fl.℥, 435 M] of percolate, and mix with the two portions (325 and 175 Cc.) previously set aside, so as to make one thousand cubic centimeters (1000 Cc.) [33 fl.℥, 391 M] of fluid extract. *Note.*—If this method is applied to drugs for which Process B is directed, use a sufficient quantity of Menstruum I to obtain the required quantities of percolate, and omit the use of Menstruum II.”

U. S. P. General Directions for Percolation.—**FINESS OF POWDER.** “The fineness of powder is expressed, in the Pharmacopœia, either by descriptive words (generally so in the case of brittle or easily pulverizable substances), or in terms expressing the number of meshes to a linear inch of the sieve through which the powder will pass. The corresponding values, in terms of metric measures of length, are added below in parentheses, but it has not been deemed advisable, in this revision, to substitute them in the text of the Pharmacopœia for those at present in use.

“These different forms of expression correspond to each other as follows:

A <i>very fine</i> powder	{ should pass through a sieve having 80 or more meshes to the linear inch (30 meshes to the centimeter). }	=No. 80 powder.
A <i>fine</i> powder	{ should pass through a sieve having 60 meshes to the linear inch (24 meshes to the centimeter). }	=No. 60 powder.
A <i>moderately fine</i> powder	{ should pass through a sieve having 50 meshes to the linear inch (20 meshes to the centimeter). }	=No. 50 powder.
A <i>moderately coarse</i> powder	{ should pass through a sieve having 40 meshes to the linear inch (16 meshes to the centimeter). }	=No. 40 powder.
A <i>coarse</i> powder	{ should pass through a sieve having 20 meshes to the linear inch (8 meshes to the centimeter). }	=No. 20 powder.

“In certain cases, powders of a different degree of fineness (*e.g.*, No. 30, No. 12) are directed to be taken.

"When a substance is directed to be in powder of a limited degree of fineness, as specified by the number of meshes to the linear inch in the sieve, not more than $\frac{1}{4}$ of the powder should pass through a sieve having 10 meshes more to the linear inch"—(U. S. P.).

PERCOLATION.—"The process of percolation, or displacement, directed in this Pharmacopœia, consists in subjecting a substance or a mixture of substances, in powder, contained in a vessel called a percolator, to the solvent action of successive portions of a certain menstruum in such a manner that the liquid, as it traverses the powder in its descent to the receiver, shall be charged with the soluble portion of it, and pass from the percolator free from insoluble matter.

"When the process is successfully conducted, the first portion of the liquid, or percolate, passing through the percolator, will be nearly saturated with the soluble constituents of the substance treated; and if the quantity of menstruum be sufficient for its exhaustion, the last portion of the percolate will be nearly free from color, odor, and taste, other than those of the menstruum itself.

"The percolator most suitable for the quantities contemplated by this Pharmacopœia should be nearly cylindrical, or slightly conical, with a funnel-shaped termination at the smaller end. The neck of this funnel-end should be rather short, and should gradually and regularly become narrower towards the orifice, so that a perforated cork, bearing a short glass tube, may be tightly wedged into it from within until the end of the cork is flush with the outer edge of the orifice. The glass tube, which must not project above the innersurface of the cork, should extend from 3 to 4 Cm. (about $1\frac{1}{2}$ to $1\frac{1}{2}$ inches) beyond the outer surface of the cork, and should be provided with a closely-fitting rubber tube, at least one-fourth longer than the percolator itself, and ending in another short glass tube, whereby the rubber tube may be so suspended that its orifice shall be above the surface of the menstruum in the percolator, a rubber band holding it in position.

"The shape of a percolator should be adapted to the nature of the drug to be operated upon. For drugs which are apt to swell, particularly when a feebly alcoholic or an aqueous menstruum is employed, a *conical* percolator is preferable. A *cylindrical*, or only slightly tapering percolator may be used for drugs which are not liable to swell, and when the menstruum is strongly alcoholic, or when ether or some other volatile liquid is used for extraction. The size of the percolator selected should be in proportion to the quantity of drug extracted. When properly packed in the percolator, the drug should not occupy more than two-thirds of its height. The percolator is best constructed of glass or stoneware, but, unless otherwise directed, may be made of any suitable material not affected by the drug or menstruum.

"The percolator is prepared for percolation by gently pressing a small tuft of cotton into the neck above the cork, a thin layer of clean and dry sand being then poured upon the surface of the cotton to hold it in place.

"The powdered substance to be percolated (which must be uniformly of the fineness directed in the formula, and should be perfectly air-dry before it is weighed) is put into a basin, the specified quantity of menstruum is poured on, and it is thoroughly stirred with a spatula, or other suitable instrument, until it appears uniformly moistened. The moist powder is then passed through a coarse sieve—No. 40 powders, and those which are finer, requiring a No. 20 sieve, whilst No. 30 powders require a No. 15 sieve for this purpose. Powders of a less degree of fineness usually do not require this additional treatment after the moistening. The moist powder is now transferred to a sheet of thick paper and the whole quantity poured from this into the percolator. It is then shaken down lightly and allowed to remain in that condition for a period varying from 15 minutes to several hours, unless otherwise directed; after which the powder is pressed, by the aid of a plunger of suitable dimensions, more or less firmly, in proportion to the character of the powdered substance and the alcoholic strength of the menstruum; strongly alcoholic menstrea, as a rule, permitting firmer packing of the powder than the weaker. The percolator is now placed in position for percolation, and, the rubber tube having been fastened at a suitable height, the surface of the powder is covered by an accurately fitting disk of filtering paper, or other suitable material, and a sufficient quantity of the menstruum poured on through a funnel reaching nearly to the surface of the paper. If these conditions be accurately

observed, the menstruum will penetrate the powder equally until it has passed into the rubber tube and has reached, in this, a height corresponding to its level in the percolator, which is now closely covered to prevent evaporation. The apparatus is then allowed to stand at rest for the time specified in the formula.

"To begin percolation, the rubber tube is lowered and its glass end introduced into the neck of a bottle previously marked for the quantity of liquid to be percolated, if the percolate is to be measured, or of a tared bottle, if the percolate is

to be weighed; and by raising or lowering this receiver the rapidity of percolation may be increased or decreased as may be desirable, care being taken, however, that the rate of percolation, unless the quantity of material be largely in excess of the pharmacopœial quantity, shall not exceed the limit of 10 to 30 drops in a minute. A layer of menstruum must constantly be maintained above the powder, so as to prevent the access of air to its interstices, until all has been added, or the requisite quantity of percolate has been obtained. This is conveniently accomplished, if the space above the powder will admit of it, by inverting a bottle containing the entire quantity of menstruum over the percolator in such a manner that its mouth may dip beneath the surface of the liquid, the bottle, being of such shape that its shoulder will serve as a cover for the percolator.

"When the dregs of a tincture, or of a similar preparation, are to be subjected to percolation, after maceration with all or with the greater portion of the menstruum, the liquid portion should be drained off as completely as possible, the solid portion packed in a percolator, as before described, and the liquid poured on, until all has passed from the surface, when immediately a sufficient quantity of the original menstruum should be poured on to displace the absorbed liquid, until the prescribed quantity has been obtained"—(U. S. P.).

REPERCOLATION.—"Authority is given to employ, in the case of Fluid Extracts,

where it may be applicable, the process of repercolation, without change of the initial menstruum"—(U. S. P.).

In addition to the foregoing, we will reproduce the following remarks from our 1881 supplement, wherein we consider in detail some points that may prove of use.

THE PERCOLATOR should be of glass where moderate amounts of material are operated upon. Large quantities require tin or wood. In all cases they should be nearly cylindrical, slightly conical, and of such diameter that the powder would occupy at least 1 foot in perpendicular height when properly packed.

To Prepare the Percolator for Percolation.—Provide a tapering cork which will perfectly close the exit or discharging aperture, so that when the percolate appears, the flow may be at once arrested. Then slice one side of the cork wedge-shape, commencing at the small end, as shown in Fig. 113, care being taken that the cut does not extend beyond that part of the cork which closes tightly the exit of the percolator. Now, place a layer of cotton upon the bottom of the percolator, as shown by Fig. 112, A; and, if convenient, a smooth layer of silver sand upon the cotton.

The percolator.

Fig. 113.

The cork.

The 16 troy ounces of powder intended for percolation should, as soon as it is ready, be placed in the percolator, about one-fourth its bulk at a time; the surface should be smoothed after each addition, and then pressed as directed, for each drug. It is necessary that the pressure be even throughout the entire mass, otherwise the liquid will select the more porous portions, and thus yield a defective percolation.

It is best to select some flat circular body or disk to use in pressing the powder, and for this purpose a circular stick of wood with a smooth end, in thickness about two-thirds the diameter of the inside of the percolator, answers very well, care being taken that all portions of the surface of the powder are submitted alike to the pressure.

By *moderately*, we understand the pressure of from 5 to 10 pounds; *firmly*, from 15 to 20 pounds; and *very firmly*, the convenient pressure of one hand, not to exceed 50 pounds. Some little practice with a pair of spring balances will enable the operator to form an idea of the pressure required. Dr. E. R. Squibb, in *New Remedies*, Jan., 1879, suggests "moderately" as a pressure of 45 pounds; firmly, 60 pounds; and hard, 75 pounds, or more. This will answer very well for large quantities, or where the pressure is exerted upon a considerable surface, as with "both hands," thus, in reality, reducing the actual pressure upon each square inch to, or below, that given by us, which is intended to apply to only 16 troy ounces of material. We are assured, from experience, that the operator will work to disadvantage if a greater pressure is employed than advised by us. Having the powder properly packed, and the surface smooth, cut a piece of filtering paper to fit closely within the percolator, and place it upon the surface of the powder, and upon this place a few fragments of glass to retain it in position. Then add the menstruum, as directed, and cover the percolator with a plate or disk of ground glass, and, when the percolate appears, close the orifice tightly with the cork, and proceed according to the process given for making the particular extract. It must be observed that the cork is not inserted in the exit of the percolator until the percolate has appeared. When the period of maceration is over, gently twist and slowly withdraw the cork until the slit previously cut upon its side permits the liquid to pass in drops, without running in a stream.

Extracts.—**EXTRACTS (solid extracts).** When an infusion, decoction, or tincture is reduced to a soft, solid mass by evaporation, either spontaneous or artificial, it is termed an *Extract*. If it be prepared from a decoction or infusion it is called a *Watery*, or *Aqueous Extract*; if from an alcoholic tincture, it forms an *Alcoholic Extract*; if both water and spirit are used in preparing it, it is termed a *Hydro-alcoholic Extract*; if ether, wine, or acetic acid be the menstruum from which it is made, it is called *Ethereal*, *Vinous*, or *Acetous Extract*, according to the fluid used. The most important point in the manufacture of extracts is to employ as a solvent a liquid that will take up the medicinal constituents of a remedy, and but little, if any, of its inert portions. The constituents of plants not desirable to extract are gum, coloring matters, saccharine matter, etc., and as these are soluble in water, and are usually less soluble in alcohol, in most cases alcohol is a better medium for obtaining the active principles. The best solvent to abstract the medicinal virtues of plants will be that fluid in which they are the most readily dissolved: thus, resins, oils, oleoresins, etc., require alcohol, and, occasionally ether; alkaloidal principles occasionally require acidulated fluids; bitter extractive requires water; and some plants contain constituents that require two or more solvents, employed successively, the several residual extracts being mixed after they have all been thus obtained. In the preparation of an extract, the operator should previously acquaint himself with the nature of the principles contained in the drug, their solubility, their relations to heat and air, their volatility, etc., so that he may adopt the menstruum best calculated to remove the greatest amount of active matter, and should control the evaporation, so that this may not be injured by heat, or lost by volatilization.

Probably no class of remedial agents requires more care in their preparation; for, if an extract be improperly prepared, either by employing a wrong solvent, or too much heat, it is not to be relied upon by the physician. In many cases the extract must be evaporated *in vacuo*, which operates against the pharmacist, for he can not afford this expensive apparatus. On this account it is very difficult for druggists or physicians to compete in this direction with manufacturers.

In some cases glycerin is useful as a part of the menstruum, both as a solvent and to prevent subsequent drying of the extract. The *U. S. P.* contains the following directions for such preparations: "When it is desired to preserve a solid extract (for instance, of gentian, taraxacum, etc.) in a plastic condition, suitable for making pills, or for other purposes, it is recommended that there be incorporated with it, after it has been evaporated to the proper consistence, and while it is still warm, 10 per cent of its weight of glycerin."—(*U. S. P.*).

Ordinarily, the plan adopted is, to obtain the juice, or tincture, of the plant, gently heat it to coagulate albuminous substances, filter or strain it, and then evaporate at a temperature ranging between 32.2° and 93.3° C. (90° and 200° F.), being careful not to raise it to the boiling point. A high temperature, as well as atmospheric action, will impair the efficiency of the preparation.

In forming the solution for *aqueous extracts*, soft water, as free from foreign matters as possible, should be employed. Clean rain water, or the water from some of our lakes or rivers, will be found to answer quite as well as water which has been distilled. The articles to be acted upon by the fluid should be ground, but not too finely, the degree of fineness depending upon the substance used, and the resulting liquid should be obtained from them by the process of displacement. The evaporation should be conducted at as low a temperature, and as quickly as the nature of the solution will admit, using a broad, shallow dish. Long continued evaporation by heat, under exposure to the atmosphere, is as detrimental to an extract as a boiling heat, hence the solutions should be procured in as concentrated a form as possible. And in those instances where different solutions are obtained, the weaker ones should be the first evaporated; by this means, the more concentrated liquids will not be injured by too long an exposure to heat.

When alcohol or ether is used in the preparation of extracts, it will be best to distill these fluids, not only for the purpose of saving them, but likewise to prevent the extracts from being impaired by atmospheric influence; a vacuum apparatus, however, will be superior to ordinary distillation, as these fluids may be evaporated at a much lower temperature. *Hydro-alcoholic extracts* are best made by first forming an alcoholic extract from the plant, then an aqueous extract, and combining the two while hot. *Ethereal extracts* are usually of a semi-fluid consistence. By means of Mohr's continuous displacing apparatus, as the percolated tincture falls into the receiver, the ether is driven off to pass again through the articles, and thus continues until all their strength is exhausted; the whole process of tincturing and forming an extract being thus performed at the same time. Extracts should be kept in glass, stone, or earthenware vessels, and be guarded as much as possible from the action of air and light, by covering them closely. The modes of preparing extracts are as follows:

1. *Aqueous Extracts*.—Take of the leaves, root, bark, or other part of the plant employed, in powder more or less fine, 1 pound; water, a sufficient quantity. Mix the leaves, or roots, etc., with half their weight of clean, soft water; in 12 hours put the whole into a displacement apparatus, and exhaust it by adding water to it from time to time, until the liquid which passes no longer contains any of the virtues of the plant, or part of it employed. Expose this filtered infusion to a temperature of 100° C. (212° F.), then strain it, and evaporate it in the vapor-bath at a temperature not to exceed 48.8° C. (120° F.), to the due consistence; or, the evaporation may be conducted in a vacuum apparatus.

2. *Alcoholic Extracts*.—Take of the leaves, root, bark, or other part of the plant employed, in powder more or less fine, 1 pound; alcohol (or diluted alcohol), water, of each, a sufficient quantity. Mix the leaves, or root, etc., with half their weight of alcohol, or enough to thoroughly moisten them; in 24 hours put the whole into a displacement apparatus, and exhaust by adding alcohol to it from time to time, until 4 pints of tincture have been obtained. Then add clean, soft water, and continue until the liquid which percolates causes a slight turbidness of the previously filtered liquor, as it drops into it. (The object of adding the water toward the latter part of the process is to remove the alcohol absorbed by the powder; and as soon as this is affected, and the water commences to percolate, it causes a turbid condition of the filtered alcoholic fluid immediately around the drops as they fall into it.) Place the filtered liquor in a suitable vacuum apparatus, and remove the alcohol, and then, if necessary, evaporate the residue in the

vapor-bath at a temperature not to exceed 48.8° C. (120° F.) to the due consistence; or, which is much better, the whole process of evaporation may be carried on in a vacuum apparatus.

3. *Hydro-alcoholic Extracts*.—Take of the leaves, root, bark, or other part of the plant employed, in powder more or less fine, 1 pound; alcohol, 90 per cent, water, of each, a sufficient quantity. Mix the leaves, or roots, etc., with half their weight of alcohol, or enough to thoroughly moisten them; in 24 hours put the whole into a displacement apparatus, and exhaust by adding alcohol to it from time to time, until it passes off without any taste of the article employed. Remove the greater part of the alcohol from this filtered tincture, and evaporate the remainder to the proper consistence in one of the ways named in the preceding pages; that *in vacuo* being the best.

To the powder in the displacement apparatus, add gradually water, a *sufficient quantity*, until the liquid which passes no longer contains any of the virtues of the plant employed. Expose this filtered infusion to a temperature of 100° C. (212° F.), then strain it, and evaporate it in the vapor-bath to the due consistence. Mix the alcoholic and aqueous extracts thus obtained, while each is hot, and stir constantly until cold. With a few exceptions, alcoholic extracts are found to be superior to any others.

Any variation from the above process, in the preparation of the following extracts will be explained under its appropriate head.

INSPISSATED JUICES are solid extracts made by evaporating the juices of fresh plants *in vacuo*. For an example see *Extract of Taraxacum*.

EXTRACTUM ACONITI (U. S. P.)—EXTRACT OF ACONITE.

SYNONYMS: *Extract of aconite root, Extractum aconiti radiceis.*

Preparation.—"Aconite, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 oz., 120 grs.]; alcohol, a sufficient quantity. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol until three thousand cubic centimeters (3000 Cc.) [101 fl̄, 212 m̄] of tincture are obtained, or the aconite is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate, evaporate the remainder in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 m̄], add the reserved portion, and evaporate, at or below the above-mentioned temperature, until an extract of a pilular consistence remains"—(U. S. P.).

Description, Medical Uses, and Dosage.—As this preparation and that formerly prepared from the leaves and still used to some extent, bear the same title, it would seem appropriate to designate this extract *Extractum Aconiti Radicis*. We have taken the liberty to name that from the leaves *Extractum Aconiti Foliorum* (see below). Extract of aconite has a yellowish-brown color, and possesses the properties of the root in a powerful degree; it may be used in *rheumatism, neuralgia, gout, scrofula, cutaneous diseases, inflammatory and febrile diseases*, and in all cases in which the use of aconite is admissible. When the extract is of good quality it causes numbness and tingling in the mouth and lips shortly after taking it. The extract prepared from the root is much more active (from 6 to 9 times stronger) than that prepared from the leaves, and should be administered in smaller doses, from $\frac{1}{16}$ to $\frac{1}{4}$ grain. The *British Pharmacopœia Extractum Aconiti* is the inspissated juice of the fresh leaves and tops, and is prescribed as *Extractum Aconiti Herbæ*.

EXTRACTUM ACONITI FOLIORUM, Extract of aconite leaves.—Exhaust coarsely powdered aconite leaves in a percolator with diluted alcohol, a sufficient quantity. From the tincture thus made separate the alcohol, and then carefully evaporate the residue until it is of the required consistence. Be careful not to spoil the extract by too high a temperature while evaporating it. The leaves should be recently dried. When the extract is prepared in large quantity a vacuum apparatus should be used in order to save the alcohol without exposure to a temperature that

would injure the active medicinal virtues of the aconite (see preparation of *Alcoholic Extract*). This extract of aconite is from 6 to 9 times weaker than the official extract of aconite, which is prepared from the root. As both the latter preparation and this one bear the same name, we have taken the liberty to designate that prepared from the leaves as *Extractum Aconiti Foliorum*. The dose is from $\frac{1}{4}$ to 1 grain 2 or 3 times a day, which may be increased to 2 grains if required.

EXTRACTUM ACONITI FLUIDUM (U. S. P.)—FLUID

EXTRACT OF ACONITE.

SYNONYMS: *Extractum aconiti radices fluidum*, *Fluid extract of aconite root*.

Preparation.—“Aconite, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 m.]. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl. 3, 173 m.] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl. 3, 218 m.] of water, and having moistened the powder with four hundred cubic centimeters (400 Cc.) [12 fl. 3, 252 m.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder, and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the aconite is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl. 3, 208 m.] of the percolate, and evaporate the remainder, in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to a soft extract, dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 m.]”—(U. S. P.).

Description, Medical Uses, and Dosage.—Fluid extract of aconite has a vivid red-brown color, and represents in 1 minim about 1 grain of aconite root. It may be used in liniments and other local applications for the relief of *rheumatic* and *neuralgic pains*. For other uses, see *Aconitum*. The dose of fluid extract of aconite is from $\frac{1}{4}$ to $\frac{1}{2}$ minim.

EXTRACTUM ALETRIDIS.—EXTRACT OF ALETRIS.

SYNONYMS: *Aletridin*, *Aletrin*, *Extract of unicorn root*.

Preparation.—Exhaust coarsely powdered unicorn root with alcohol, proceeding in the same manner as explained for general preparation of alcoholic extracts.

Medical Uses and Dosage.—This forms a very elegant and useful preparation of unicorn root. It may be used as a tonic in cases of *debility* of the digestive organs, and is also asserted valuable in *uterine difficulties*, as *prolapsus*, *amenorrhœa*, *dysmenorrhœa*, etc. The dose is from $\frac{1}{2}$ to 2 grains, 3 times a day.

EXTRACTUM ALETRIDIS FLUIDUM (N. F.)—FLUID

EXTRACT OF ALETRIS.

Preparation.—*Formulary number*, 137: “From the rhizome of *Aletris farinosa*, Linné (*Stargrass*). *Process A* (see F. 135). No. 60 powder. *Menstruum*: Diluted alcohol”—(Nat. Form.).

In our opinion this fluid extract should be made with official alcohol. Aletris depends altogether for its therapeutical value on resinous bodies. It is a favorite Eclectic remedy and usage establishes that water added to the menstruum injures the product about in proportion to the water present.

Medical Uses and Dosage.—(See *Aletris*). Dose, 1 to 60 minims.

EXTRACTUM ALOES (U. S. P.)—EXTRACT OF ALOES.

SYNONYMS: *Extractum aloes socotrinæ*, *Extract of socotrine aloes*.

Preparation.—“Socotrine aloes, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; boiling distilled water, one thousand cubic centimeters (1000 Cc.) [33 fl. 3,

391 M]. Mix the aloes with the water in a suitable vessel, stirring constantly until the particles of aloes are thoroughly disintegrated, and let the mixture stand for 12 hours; then pour off the clear liquor, strain the residue, mix the liquids, and evaporate to dryness by means of a water or steam bath"—(U. S. P.).

Description, Medical Uses, and Dosage.—The process here employed is one of purification. The object sought in the large quantity of water used is the removal of the resin, which is not, however, wholly accomplished. Therefore the finished product does not dissolve perfectly clear in water. This results partly from organic decomposition, partly from the fact that an equilibrium is not established in 12 hours, and partly because a solution of water-soluble constituents makes a solvent that can hold in solution substances insoluble in pure water. The uses are those of aloes, and the dose from 1 to 10 grains.

EXTRACTUM ALSTONIAE CONSTRICTAE FLUIDUM.—FLUID

EXTRACT OF ALSTONIA CONSTRICTA.

Preparation.—Take of the inner bark of *Alstonia constricta*, in very fine powder, 16 troy ounces; alcohol, a sufficient quantity. Moisten the powder with 8 fluid ounces of alcohol. Cork tightly in a wide-mouth bottle, and permit the mixture to stand an hour in a warm situation. Then introduce it into a cylindrical percolator, 3 inches in diameter, previously prepared for percolation, according to directions given on page 756, and press very firmly. Cover the surface of the powder with a circular piece of filtering paper, held in position with a few fragments of glass or marble, and add alcohol until the percolate appears at the exit. Then cork the exit tightly; cover the percolator, and place it in a warm situation. After 24 hours, loosen the cork, and permit the percolate to pass as fast as it will drop, without running in a stream, until 4 fluid ounces are obtained. Again close the exit, macerate 24 hours, and, in a manner like unto the preceding, draw 4 fluid ounces of percolate. Repeat the maceration, and, in like manner, draw a third portion of 4 fluid ounces. Reserve, and mix the three percolates; then continue the percolation until 8 fluid ounces are obtained. Evaporate this latter portion until reduced to the measure of 2 fluid ounces, and mix with the reserved 12 fluid ounces. The surface of the powder must be constantly covered with alcohol from the commencement, and until the end of the percolation.

Description, Medical Uses, and Dosage.—(See *Alstonia constricta*). Fluid extract of *Alstonia constricta* is of a dark yellowish-red color, odorless, and possesses the intense bitterness peculiar to the drug. When prepared according to the foregoing formula, it seems to represent very nearly the entire sensible properties of the bark employed, troy ounce to each fluid ounce of the finished extract. Dose, from 5 to 40 minims.

EXTRACTUM ALSTONIAE SCHOLARIS FLUIDUM.—FLUID

EXTRACT OF ALSTONIA SCHOLARIS.

Preparation.—Take of the bark of *Alstonia scholaris*, in moderately fine powder, 16 troy ounces; of a menstruum of alcohol 3 parts, water 2 parts (by measure), a sufficient quantity; moisten the powder with 8 fluid ounces of the menstruum. Cork tightly in a wide-mouth bottle, and permit the mixture to stand an hour in a warm situation. Then introduce it into a cylindrical percolator, 3 inches in diameter, previously prepared for percolation, according to directions given on page 756, and press very firmly. Cover the surface of the powder with a circular piece of filtering paper held in position with a few fragments of glass or marble, and add fresh menstruum until the percolate appears at the exit. Then cork the exit tightly; cover the percolator, and place in a warm situation. After 24 hours, loosen the cork and permit the percolate to pass as fast as it will drop, without running in a stream, until 4 fluid ounces are obtained. Again close the exit, macerate 24 hours, and, in a manner like unto the preceding, draw 4 fluid ounces of percolate. Repeat the maceration, and, in like manner, draw a third portion of 4 fluid ounces. Reserve, and mix the three percolates; then continue the percolation until 8 fluid ounces are obtained. Evaporate this

latter portion until reduced to the measure of 2 fluid ounces, and mix with the reserved 12 fluid ounces. The surface of the powder must be constantly covered with the menstruum from the commencement, and until the end of the process of percolation.

Description, Medical Uses, and Dosage.—(See *Alstonia scholaris*). Fluid extract of *Alstonia scholaris* is of a reddish color, odorless, possesses a bitterish taste, and as thus prepared, represents very nearly the quality of drug employed, troy ounce to each fluid ounce of the finished extract. Dose, 10 to 60 minima.

EXTRACTUM ANGELICÆ RADICIS FLUIDUM (N. F.)—FLUID EXTRACT OF ANGELICA ROOT.

Preparation.—*Formulary number*, 135: "From the root of *Angelica Archangelica*, Linne (*Angelica*). *Process A* (see F. 135). No. 60 powder. *Menstruum*: Alcohol, 3 volumes; water, 2 volumes"—(*Nat. Form.*).

Medical Uses and Dosage.—(See *Angelica*). Dose, 10 to 60 minima.

EXTRACTUM ANTHEMIDIS.—EXTRACT OF CHAMOMILE.

Preparation.—"Take of chamomile flowers 1 pound (av.), oil of chamomile 15 minims, distilled water 1 gallon. Boil the chamomile with the water until the volume is reduced to one-half; then strain, press, and filter. Evaporate the liquor by a water-bath until the extract is of a suitable consistence for forming pills, adding the oil of chamomile at the end of the process (*Br. Pharm.*). This is an aqueous extract of deep-brown color, representing the odor and bitter taste of the flowers. An alcoholic extract may be prepared as follows:

EXTRACTUM ANTHEMIDIS ALCOHOLICUM, Alcoholic extract of chamomile.—Exhaust chamomile flowers, bruised, 1 pound, with diluted alcohol a sufficient quantity, proceeding in the same manner as explained for the preparation of *Alcoholic Extracts*, on page 758. At the close of the process volatile oil of chamomile, 15 minims, may be thoroughly incorporated with the extract, as advised by the *British Pharmacopæia*.

Medical Uses and Dosage.—Extract of chamomile is a tonic, and may be used in all cases where the crude article is indicated. It may be beneficially combined with other extracts, as of scullcap, cramp-bark, black cohosh, golden-seal, ladies'-slipper, etc. The dose of the alcoholic extract is from 1 to 5 grains 3 times a day; of the aqueous extract, 1 to 10 grains.

EXTRACTUM ANTHEMIDIS FLUIDUM.—FLUID EXTRACT OF CHAMOMILE.

Preparation.—Take of chamomile flowers in powder 16 troy ounces, of a mixture of alcohol 3 parts, water 2 parts, a sufficient quantity. Moisten; proceed according to formula of fluid extract of *Alstonia scholaris* ending with the word *percolation*.

Medical Uses and Dosage.—This fluid extract of chamomile flowers is a tonic, and possesses all the properties of the crude article. Each fluid ounce of the extract represents a fluid ounce of the flowers; hence the dose is from 1 to 60 drops, 3 times a day. It may be advantageously combined with the fluid extracts of *cimicifuga*, *valeriana*, *cypripedium*, *scutellaria*, etc.

EXTRACTUM APII GRAVEOLENTIS FLUIDUM (N. F.)—FLUID EXTRACT OF CELERY.

Preparation.—*Formulary number*, 139: "From the seed of *Apium graveolens*, Linné (*Celery*). *Process A* (see F. 135). No. 60 powder. *Menstruum*: Alcohol, 2 volumes; water, 1 volume"—(*Nat. Form.*).

Medical Uses and Dosage.—(See *Apium graveolens*). Dose, 10 to 30 minima.

EXTRACTUM APOCYNII.—EXTRACT OF BITTER ROOT.

SYNONYM: *Extract of Indian hemp.*

Preparation.—Exhaust coarsely powdered Indian hemp (*Apocynum cannabinum*), 1 pound, with alcohol, water, of each, a sufficient quantity, proceeding in the same manner as explained for the preparation of Alcoholic Extracts, on page 758. This extract, either dried or not, has been sold and employed in therapeutics under the erroneous name of *apocynin*.

Medical Uses and Dosage.—This extract is purgative, and either alone or in combination with extract of leptandra, has been employed in *affections of the liver and stomach*, in *intermittents*, and formerly in the *low stage of typhoid fever*. It has also been employed with advantage as a diuretic and emmenagogue. The dose is from 1 to 10 grains, 2 or 3 times a day.

EXTRACTUM APOCYNII FLUIDUM (U. S. P.)—FLUID EXTRACT OF APOCYNUM.

SYNONYM: *Fluid extract of Canadian hemp.*

Preparation.—“Apocynum, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 m̄]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix the glycerin with six hundred and fifty cubic centimeters (650 Cc.) [21 fl̄, 470 m̄] of alcohol and two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄] of water, and having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward a mixture of alcohol and water, made in the proportion of six hundred and fifty cubic centimeters (650 Cc.) [21 fl̄, 470 m̄] of alcohol to three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄] of water until the apocynum is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.). In our opinion the glycerin has no value in this preparation, being inferior to alcohol. A better menstruum is a mixture of alcohol 3 parts, water 1 part.

Medical Uses and Dosage.—(See *Apocynum*). Dose, 1 to 20 minims.

EXTRACTUM ARALIE RACEMOSÆ FLUIDUM (N. F.)—FLUID EXTRACT OF ARALIA RACEMOSA.

Preparation.—Formulary number, 140: “From the root of *Aralia racemosa*, Linné (*American spikenard*). Process A (see F. 135). No. 60 powder. Menstruum: Alcohol, 2 volumes; water, 1 volume”—(Nat. Form.).

Medical Uses and Dosage.—(See *Aralia racemosa*). Dose, 10 to 60 minims.

EXTRACTUM ARNICÆ RADICIS (U. S. P.)—EXTRACT OF ARNICA ROOT.

Preparation.—“Arnica root, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lb. av., 3 oz., 120 grs.]; diluted alcohol, a sufficient quantity. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of diluted alcohol, and pack it firmly in a cylindrical percolator; then

add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the arnica root is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate; evaporate the remainder to one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 m̄], at a temperature not exceeding 50° C. (122° F.), mix the residue with the reserved portion, and evaporate, at or below the above mentioned temperature, to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Arnica*). A brown extract of feeble odor and a bitter, acrid taste. Used chiefly in plasters. Dose, 3 to 5 grains.

EXTRACTUM ARNICÆ RADICIS FLUIDUM (U. S. P.)—FLUID

EXTRACT OF ARNICA ROOT.

Preparation.—“Arnica root, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lb. av., 3 oz., 120 grs.]; alcohol, water, each, a sufficient quantity, to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 m̄] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder, and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportion of alcohol and water as before, until the arnica root is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Arnica*). A reddish-brown fluid possessing the bitter, acrid taste of arnica root. Dose, 10 to 30 minims.

Related Preparation.—EXTRACTUM ARNICÆ FLORUM FLUIDUM (N. F.), *Fluid extract of arnica flowers*. *Formulary number*, 141: “From the flower heads of *Arnica montana*, Linneé (*Arnica*). *Process*. 1 (see F. 135). No. 40 powder. *Menstruum*: Diluted alcohol”—(*Nat. Form.*).

EXTRACTUM AROMATICUM.—AROMATIC EXTRACT.

Preparation.—Take of cinnamon, ginger, each, in fine powder, 3 troy ounces; cardamom, free from capsules, nutmeg, each, in fine powder, 1½ troy ounces; sugar, 9 troy ounces; alcohol of sp. gr. 0.817, a sufficient quantity. Mix all the powdered aromatics, put the mixture in a percolator, and gradually add alcohol until the mixture is exhausted; pour the resulting percolate over the sugar, evaporate at a low heat until dry, agitating constantly toward the end of the process.

Medical Uses and Dosage.—This forms a pleasant stimulant and carminative, which may be used in cases of *flatulency*, in *gastric debility*, and to render other medicines more palatable. It answers all the purposes of the “*Aromatic powder*,” now official, and “*Aromatic confection*,” formerly official in the U. S. P. The dose is from 5 to 60 grains. Added to wine it forms a very good *Aromatic wine*.

EXTRACTUM AROMATICUM FLUIDUM (U. S. P.)—AROMATIC

FLUID EXTRACT.

Preparation.—Aromatic powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with three hundred

and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 M] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol until the aromatic powder is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 M] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M].

Description, Medical Uses, and Dosage.—A rich, red-brown fluid, possessing a warm taste and aromatic flavor. Used for flavoring, and, in doses of $\frac{1}{4}$ to 1 fluid drachm, as a carminative.

EXTRACTUM ASOLEPIADIS.—EXTRACT OF ASOLEPIAS.

SYNONYM: *Extract of pleurisy root.*

Preparation.—Exhaust coarsely powdered pleurisy root, 1 pound, with alcohol, water, of each, a sufficient quantity, proceeding in the manner as explained for the preparation of Alcoholic Extracts on page 758 (J. King).

Medical Uses and Dosage.—Alcoholic extract of pleurisy root is expectorant, tonic, laxative, and antispasmodic. It will be found useful in chronic and acute catarrhal coughs, rheumatic affections, dysentery, etc. From its peculiar action upon the ligaments of the uterus, it proves highly beneficial in *prolapsus*, and other displacements of this organ. The dose is from 3 to 10 or 15 grains, 3 times a day.

EXTRACTUM ASOLEPIADIS FLUIDUM (U. S. P.)—FLUID EXTRACT OF ASOLEPIAS.

SYNONYM: *Fluid extract of pleurisy root.*

Preparation.—“*Asclepias*, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 M] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the *asclepias* is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 M] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Asclepias*.) A brown-red fluid. Dose, 5 to 60 minims.

EXTRACTUM ASPIDOSPERMATIS FLUIDUM (U. S. P.)—FLUID EXTRACT OF ASPIDOSPERMA.

SYNONYM: *Fluid extract of quebracho.*

Preparation.—“*Aspidosperma*, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Mix the glycerin with six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 M] of alcohol and three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 M] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 M] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the

percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then a mixture of alcohol and water, made in the proportion of two hundred cubic centimeters (200 Cc.) [6 fl̄, 366 m̄] of alcohol to one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 m̄] of water, until the *Aspidosperma* is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.) to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄].”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Aspidosperma*). Dose, 15 to 60 minims.

EXTRACTUM AURANTII AMARI FLUIDUM (U. S. P.)—FLUID EXTRACT OF BITTER ORANGE PEEL.

Preparation.—“Bitter orange peel, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 m̄] of alcohol with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of water, and, having moistened the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄] of the mixture, pack it moderately in a conical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the orange peel is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄].”—(U. S. P.).

Description, Medical Uses, and Dosage.—When properly prepared from good orange peel this fluid has a yellowish-brown hue, and possesses the pleasant flavor and agreeable bitterness of the crude drug. Used chiefly as a flavoring agent. Dose, 1 fluid drachm.

EXTRACTUM BAPTISLE.—EXTRACT OF BAPTISIA.

SYNONYM: *Extract of wild indigo.*

Preparation.—Exhaust coarsely powdered bark of wild indigo root, 1 pound, with alcohol, water, each, a sufficient quantity, proceeding in the same manner as explained for the preparation of Alcoholic Extracts.

Medical Uses and Dosage.—This extract is antiseptic, with purgative and emetic properties when taken in large doses. It is especially advantageous in *typhoid conditions* of the system, in *malignant ulcerations of the mouth and throat*, in *scarlatina*, and in all cases where there is a tendency to *putrescency or gangrene*. It exerts a powerful stimulant effect on the glandular and nervous systems, and will be found useful in *scrofula*, *obstinate hepatic torpor*, etc. Its virtues are increased by combination with extract of *leptandra*, resin of *podophyllum* or *cimicifuga*. The dose is $\frac{1}{2}$ grain, gradually increased to 1 or 2 grains, and repeated 3 times a day (J. King).

EXTRACTUM BELLADONNÆ FOLIORUM ALCOHOLICUM (U. S. P.) ALCOHOLIC EXTRACT OF BELLADONNA LEAVES.

SYNONYM: *Extractum belladonnæ alcoholicum (Pharm., 1880).*

Preparation.—“Belladonna leaves, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity. Mix two thousand cubic centimeters (2000 Cc.) [67 fl̄, 301 m̄] of alcohol with one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄

252 M.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until three thousand cubic centimeters (3000 Cc.) [101 fl̄, 212 M.] of tincture are obtained, or the belladonna leaves are exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 M.] of the percolate, evaporate the remainder at a temperature not exceeding 50° C. (122° F.), to one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M.], mix the residue with the reserved portion, and evaporate at or below the above-mentioned temperature to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—This extract possesses the odor and taste of belladonna, and is greenish-brown or brownish-green in color. It is used chiefly, locally, to allay *pain* and to control *spasm*. Its internal use is the same as for belladonna. The dose ranges from $\frac{1}{4}$ to $\frac{1}{2}$ grain, 3 times a day.

EXTRACTUM BELLADONNÆ RADICIS FLUIDUM (U. S. P.)—FLUID EXTRACT OF BELLADONNA ROOT.

SYNONYM: *Extractum belladonnæ fluidum* (Pharm., 1880).

Preparation.—"Belladonna root, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]. Mix eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 M.] of alcohol with two hundred cubic centimeters (200 Cc.) [6 fl̄, 366 M.] of water, and, having moistened the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 M.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the belladonna root is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 M.] of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]"—(U. S. P.).

Description, Medical Uses, and Dosage. (See *Belladonna*.) Fluid extract of belladonna root has a reddish-brown color. The dose ranges from $\frac{1}{4}$ to 2 minims.

EXTRACTUM BERBERIDIS AQUIFOLII FLUIDUM.—FLUID EXTRACT OF BERBERIS AQUIFOLIUM.

Preparation.—Take of the root of *Berberis aquifolium*, in moderately fine powder, 16 troy ounces; of a menstruum of alcohol, 3 parts, water, 2 parts (by measure), a sufficient quantity. Moisten the powder with 6 fluid ounces of the menstruum. Cork tightly in a wide-mouthed bottle, and permit the mixture to stand an hour in a warm situation. Then introduce into a cylindrical percolator, 3 inches in diameter, previously prepared for percolation, according to directions given on page 756, and press moderately. Cover the surface of the powder with a circular piece of filtering paper, held in position with a few fragments of glass or marble, and add fresh menstruum until the percolate appears at the exit. Then cork the exit tightly; cover the percolator, and place it in a warm situation. After 24 hours, loosen the cork, and permit the percolate to pass as fast as it will drop, without running in a stream, until 4 fluid ounces are obtained. Again close the exit, macerate 24 hours, and, in a manner like unto the preceding, draw 4 fluid ounces of percolate. Repeat the maceration, and, in like manner, draw a third portion of 4 fluid ounces. Reserve and mix the 3 percolates;

then continue the percolation until 8 fluid ounces are obtained. Evaporate this latter portion until reduced to the measure of 2 fluid ounces, and mix with the reserved 12 fluid ounces. The surface of the powder must be constantly covered with the menstruum from the commencement, and until the end of the process of percolation.

Description, Medical Uses, and Dosage.—(See *Berberis aquifolium*). Fluid extract of *Berberis aquifolium* is of a yellowish-red color, odorless, or nearly so, and very bitter to the taste, and, as thus prepared, represents very nearly the quality of the drug employed, troy ounce to each fluid ounce of the finished extract. Dose, 5 to 20 drops.

EXTRACTUM BERBERIDIS VULGARIS FLUIDUM (N. F.)—FLUID EXTRACT OF BERBERIS VULGARIS.

Preparation.—*Formulary number, 142:* "From the bark of the root of *Berberis vulgaris*, Linné (*Barberry*). *Process A* (see F. 135). No. 60 powder. *Menstruum:* Alcohol, 3 volumes; water, 2 volumes"—(*Nat. Form.*).

Medical Uses and Dosage.—(See *Berberis vulgaris*). Dose, 5 to 30 minims.

EXTRACTUM BOLDO FLUIDUM.—FLUID EXTRACT OF BOLDO.

SYNONYM: *Fluid extract of Peumus boldo.*

Preparation.—Take of boldo leaves, in very fine powder, 16 troy ounces; alcohol, a sufficient quantity. Moisten the boldo with 6 fluid ounces of alcohol. Cork tightly in a wide-mouth bottle, and permit the mixture to stand an hour in a warm situation. Then introduce it into a cylindrical percolator, 3 inches in diameter, previously prepared for percolation, according to directions given on page 756, and press very firmly. Cover the surface of the powder with a circular piece of filtering paper, held in position with a few fragments of glass or marble, and add alcohol until the percolate appears at the exit. Then cork the exit tightly; cover the percolator, and place it in a warm situation. After 24 hours, loosen the cork, and permit the percolate to pass as fast as it will drop, without running in a stream, until 4 fluid ounces are obtained. Again close the exit, macerate 24 hours, and in a manner like unto the preceding, draw 4 fluid ounces of percolate. Repeat the maceration, and, in like manner, draw a third portion of 4 fluid ounces. Reserve, and mix the three percolates; then continue the percolation until 8 fluid ounces are obtained. Evaporate this latter portion until reduced to the measure of 2 fluid ounces, and mix with the reserved 12 fluid ounces. The surface of the powder must be constantly covered with alcohol from the commencement, and until the end of the process of percolation.

Description, Medical Uses, and Dosage.—(See *Boldo*). Fluid extract of boldo is dark-green in color, of a disagreeable wormseed-like odor and taste, and as thus prepared, represents very nearly the quality of drug employed, troy ounce for each fluid ounce of the finished extract. Dose, 5 to 20 minims.

EXTRACTUM BRYONIAE FLUIDUM.—FLUID EXTRACT OF BRYONIA.

Preparation.—Take of bryonia root, in moderately fine powder, 16 troy ounces; alcohol and water, each, a sufficient quantity. Moisten the bryonia with 3 fluid ounces of water, and permit the mixture to stand 1 hour in a well-corked wide-mouth bottle. Then intimately rub it with 6 fluid ounces of alcohol, and allow the mixture to macerate an hour as before. Introduce this, with moderate pressure, into a cylindrical percolator, 3 inches in diameter, that has been previously prepared for percolation, according to directions given on page 756. Cover the surface of the powder with a circular piece of filtering paper, held in position with a few fragments of glass or marble, and add a mixture of alcohol, by measure, 2 parts, until the percolate appears at the exit. Then cork the exit tightly; cover the percolator, and place it in a warm situation. After 24 hours, loosen the

cork, and permit the percolate to pass as fast as it will drop, without running in a stream, until 4 fluid ounces are obtained. Again close the exit, macerate 24 hours, and, in a manner like unto the preceding, draw 4 fluid ounces of percolate. Repeat the maceration, and, in like manner, draw a third portion of 4 fluid ounces. Reserve, and mix the three percolates; then continue the percolation until 8 fluid ounces are obtained. Evaporate this latter until reduced to the measure of 2 fluid ounces, and mix with the reserved 12 fluid ounces. The surface of the powder must be constantly covered with menstruum from the commencement, and until the end of the process of percolation.

Description, Medical Uses, and Dosage.—Fluid extract of bryonia is dark red in color, and, as thus prepared, represents very nearly the quality of the drug employed, troy ounce to each fluid ounce of the finished extract. The preliminary use of water in moistening this drug brings it to a condition which favors the ready permeation of the menstruum. (For uses, see *Bryonia*). Dose, 1 to 2 drops.

EXTRACTUM BUCHU FLUIDUM (U. S. P.)—FLUID EXTRACT OF BUCHU.

Preparation.—"Buchu, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the buchu is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—Fluid extract of buchu has a clear, deep-green color, and the taste and odor of buchu leaves. It is a gently stimulating diuretic, and may be used in *chronic catarrh of the bladder, gravel, morbid irritation of the bladder and urethra*, and other affections of the urinary organs. The dose is from 20 to 60 minims 3 times a day.

Related Preparation.—EXTRACTUM BUCHU FLUIDUM COMPOSITUM (N. F.), *Compound fluid extract of buchu*. *Formulary number*, 144: "Buchu, six hundred and twenty-five grammes (625 Gm.) [1 lb. av., 6 ozs., 20 grs.]; cubeb, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; juniper, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; uva ursi, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]. *Process A* (see F. 135). No. 40 powder. *Menstruum*: Alcohol, 2 volumes; water, 1 volume"—(Nat. Form.).

EXTRACTUM CALAMI FLUIDUM (U. S. P.)—FLUID EXTRACT OF CALAMUS.

Preparation.—"Calamus, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lb. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity, to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol until the calamus is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—This preparation has the characteristic taste and odor of calamus. If made from peeled calamus, it is of a brown-yellow color; if from unpeeled root, it has a deeper hue. Uses same as calamus. Dose, 5 to 20 minims.

EXTRACTUM CALENDULÆ FLUIDUM (N. F.)—FLUID EXTRACT OF CALENDULA.

Preparation.—*Formulary number, 145:* "From the flowering herb of *Calendula officinalis*, Linné (*Marigold*). *Process A* (see F. 135). No. 40 powder. *Menstruum:* Alcohol, 2 volumes; water, 1 volume"—(*Nat. Form.*).

Medical Uses and Dosage.—(See *Calendula*). Dose, 2 to 20 minims.

EXTRACTUM CALUMBÆ.—EXTRACT OF CALUMBA.

SYNONYM: *Extractum columbo.*

Preparation.—"Take of calumba root, cut small, 1 pound (av.); proof spirit, 4 pints (Imp.). Macerate the calumba with 2 pints of the proof spirit for 12 hours, strain and press. Macerate again with the same quantity of proof spirit, strain and press as before. Mix and filter the liquors, recover the spirit by distillation, and evaporate the residue by the heat of a water-bath until the extract is of a suitable consistence for forming pills" (*Br. Pharm.*).

Medical Uses and Dosage.—(See *Calumba*). Dose, 2 to 10 grains.

EXTRACTUM CALUMBÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF CALUMBA.

Preparation.—"Calumba, in No. 20 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 gra.]; alcohol, water, each, a sufficient quantity, to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 m̄] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄] of water, and, having moistened the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the calumba is exhausted. Reserve the first seven hundred cubic centimeters (700 Cc.) [23 fl̄, 321 m̄] of the percolate. Distill off the alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract, dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(*U. S. P.*).

Description, Medical Uses, and Dosage.—(See *Calumba*). An intensely bitter, deep or orange-brown fluid. Dose, 10 to 30 minims.

EXTRACTUM CAMELLIÆ FLUIDUM (N. F.)—FLUID EXTRACT OF CAMELLIA.

Preparation.—*Formulary number, 146:* "From the commercial dried leaves of *Camellia Thea*, Link (*Tea*). *Process B* (see F. 135). No. 40 powder. *Menstruum I:* Alcohol, two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄]; water, six hundred and eighty-five cubic centimeters (685 Cc.) [23 fl̄, 78 m̄]; glycerin, sixty-five cubic centimeters (65 Cc.) [2 fl̄, 95 m̄]. *Menstruum II:* Alcohol, 1 volume; water, 3 volumes. *Note.*—It is recommended that the best quality of commercial black tea, preferably "Formosa Oolong," be employed for this preparation"—(*Nat. Form.*).

Medical Uses and Dosage.—(See *Thea*) Dose, 5 to 60 minims.

EXTRACTUM CANNABIS INDICÆ (U. S. P.)—EXTRACT OF INDIAN CANNABIS.

SYNONYM: *Extract of Indian hemp.*

Preparation.—"Indian cannabis, in No. 20 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity. Moisten the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 M] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the cannabis is exhausted. Distill off the alcohol from the tincture by means of a water-bath, and evaporate the residue in a porcelain capsule, on a water-bath, to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—This forms a dark, dull-green extract, having the well-marked odor of hemp resin, is soluble in strong alcohol, ether, chloroform, olive oil, and oil of turpentine, the latter solution depositing minute, scaly crystals on standing; almost wholly soluble in benzol; not affected by alkalis; and with cold nitric acid, sp. gr. 1.38, it is slowly acted on, evolving red fumes, being converted into an orange-red resinoid substance, about as abundant as the resin treated, and which, when washed with water and dried, resemble minute fragments of gamboge (W. Procter, Jr., *Proc. Amer. Pharm. Assoc.*, 1864, pp. 246-7). Much of the drug, cannabis indica, is moldy, partly decayed, and unfit for use. As a rule, this extract of cannabis is dull in color, and inferior to the extract purified according to the following method, which yields a deep-green, alcohol-soluble preparation. Uses, those of cannabis. Dose, $\frac{1}{4}$ grain, increased gradually until its effects are produced. On account of the variability of the preparation, the dose is not definitely established.

Related Preparation.—The following is Prof. Procter's method of preparing *Purified extract of Indian hemp*: EXTRACTUM CANNABIS PURIFICATUM, *Extract of Indian hemp, purified.*—Take of the green extract of Indian hemp, imported from India, 1½ troy ounces; triturate it thoroughly with alcohol, sp. gr. 0.820, 1½ fluid ounces; and then add to it of the same alcohol, 9 fluid ounces. Let the whole macerate for 36 hours, filter, and, while on the filter, add more alcohol until the extract is thoroughly exhausted. Evaporate the filtrate to dryness in a water-bath, at a temperature not exceeding 65.5° C. (150° F.). The uses are the same as stated under Cannabis. This extract, being purified, and possessing greater uniformity of strength than the ordinary commercial extract, should be administered in somewhat smaller doses. For making chlorodyne, this preparation is to be preferred to the extract made of the herb by the preceding process.

EXTRACTUM CANNABIS INDICÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF INDIAN CANNABIS.

SYNONYM: *Fluid extract of Indian hemp.*

Preparation.—"Indian cannabis, in No. 20 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity, to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Moisten the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 M] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol until the Indian cannabis is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 M] of the percolate. Distill off the alcohol from the remainder by means of a water-bath, and evaporate the residue, in a porcelain capsule, to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See Cannabis). A deep-green fluid. Dose, $\frac{1}{2}$ to 10 minims. In our opinion, a fluid extract made by dissolving a given amount of the purified extract of the preceding formula in official alcohol, is to be preferred to the foregoing.

EXTRACTUM CAPSICI FLUIDUM (U. S. P.)—FLUID EXTRACT OF CAPSICUM.

SYNONYM: *Fluid extract of red pepper.*

Preparation.—"Capsicum, in No. 60 powder, one thousand grains (Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. oz., 391 Ml.]. Moisten the powder with one hundred cubic centimeters (500 Cc.) [16 fl. oz., 435 Ml.] of alcohol, and place in a cylindrical percolator; then add enough alcohol to saturate the powder, and leave a stratum above it. When the liquid begins to drop from the powder, close the lower orifice, and, having closely covered the percolator, macerate for 24 hours. Then allow the percolation to proceed, gradually adding alcohol until the capsicum is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl. oz., 208 Ml.] of the percolate, and evaporate the remainder to dryness; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl. oz., 391 Ml.]"—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a rich, brownish liquid, possessing the characteristic properties of capsicum. It is likely to deposit a brown, flocculent sediment by age, which, however, seems not to impart to the extract any loss of activity. **Dose,** $\frac{1}{2}$ to 2 minims.

EXTRACTUM CASCARÆ SAGRADÆ.—EXTRACT OF CASCARA SAGRADA.

SYNONYM: *Extractum rhamni purshianæ.*

Preparation.—"Take of Cascara sagrada, in No. 40 powder, 1 part; proof spirit, distilled water, of each, a sufficiency. Mix the cascara with an equal part of the spirit, and macerate in a closed vessel for 48 hours; then transfer to a percolator, and when the fluid ceases to pass, continue the percolation with distilled water until 3 pints of liquid have been collected, or the cascara is exhausted. Evaporate the percolated liquid by a water-bath until the extract has acquired a thick consistence"—(Br. Pharm.).

Medical Uses and Dosage.—(See *Rhamnus Purshiana*.) A good cathartic use in pills. **Dose,** 2 to 8 grains.

EXTRACTUM CAULOPHYLLI.—EXTRACT OF CAULOPHYLLUM.

SYNONYM: *Extract of blue cohosh.*

Preparation.—Exhaust coarsely powdered blue cohosh root, 16 parts, with alcohol, water, of each, a sufficient quantity, proceeding in the same manner as explained for the preparation of Alcoholic Extracts (see *Resin of Erythrina*).

Medical Uses and Dosage.—Alcoholic extract of blue cohosh is a tonic and parturient. It may be advantageously combined with extract of iron, in *bilious colic, flatulency, and griping pains* arising from the use of purgatives; with oleoresin of prickly ash bark, alcoholic extracts of *cinna latifolia*, *scutellaria*, in *rheumatic affections*; and with oleoresin of *senecio*, resin of *fuga*, alcoholic extracts of *aletris*, *asclepias*, or high cranberry bark, in *menstrual disorders*. It will be found very useful in *amenorrhœa* and *dysmenorrhœa*; also, with hydrochlorate of berberine an elegant remedy for *deranged conditions of the stomach, dyspepsia*, etc. It has also been found serviceable in *after-pains*. **Dose** is from 1 to 5 grains, 3 times a day (J. King).

EXTRACTUM CAULOPHYLLI FLUIDUM (N. F.)—FLUID EXTRACT OF CAULOPHYLLUM.

Preparation.—Formulary number, 147: "From the rhizome and root of *Caulophyllum thalictroides*, Michaux (Blue cohosh). **Process A** (see F. 135). No. 100 powder. **Menstruum:** Alcohol, 3 volumes; water, 1 volume"—(Nat. Form.).

Medical Uses and Dosage.—(See *Caulophyllum*). **Dose,** 5 to 30 minims.

EXTRACTUM CELASTRI FLUIDUM.—FLUID EXTRACT OF CELASTRUS.

SYNONYM: *Fluid extract of false bittersweet.*

Preparation.—Take of the recently dried bark of the root of false bittersweet, in fine powder, 16 troy ounces; diluted alcohol, a sufficient quantity. Moisten the powdered bark thoroughly with part of the diluted alcohol, and let it stand for 24 hours; then transfer it to a percolator, and gradually add diluted alcohol until 12 fluid ounces have been obtained. Set this aside; then add diluted alcohol until the bark is exhausted; evaporate this to 4 fluid ounces, and add it to the 12 fluid ounces first obtained, so as to make a pint of fluid extract.

Medical Uses and Dosage.—This fluid extract possesses the same virtues as the bark (see *Celastrus*), in doses of from $\frac{1}{2}$ fluid drachm to 1 fluid drachm, 3 times a day.

EXTRACTUM CHIMAPHILÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF CHIMAPHILA.

Preparation.—“Chimaphila, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol until the chimaphila is exhausted. Reserve the first seven hundred cubic centimeters (700 Cc.) [23 fl̄, 321 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Chimaphila*). A deep, brownish-green fluid of a somewhat thick consistence. It is inferior to the infusion as a remedy. Dose, 60 minims, well diluted, 3 or 4 times a day.

EXTRACTUM CHIRATÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF CHIRATA.

Preparation.—“Chirata, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 m̄] of alcohol with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of water, and, having moistened the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄] of the mixture, pack it firmly in a cylindrical percolator: then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the chirata is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 m̄] of the percolate. Distill off the alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a reddish-brown, intensely bitter fluid. Water fully extracts the virtues of chirata, but, as decomposition takes place by age, this is sought to be avoided by the addition of alcohol, which

does not, however, wholly prevent subsequent deposition. This preparation is so little used as to make it a lumberer of the Pharmacopœia. *U. S. P.* *chirata*. Dose, 10 to 30 minims.

EXTRACTUM CIMICIFUGÆ (U. S. P.)—EXTRACT OF CIMICIFUGA

SYNONYM: *Extract of black cohosh.*

Preparation.—"Cimicifuga, in No. 60 powder, one thousand grammes (Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity. Moisten the powder with two hundred and fifty cubic centimeters (250 Cc.) [8 fl. oz.] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the cimicifuga is exhausted. Distill off the alcohol from the tincture by means of a water-bath, and evaporate the residue on a water-bath, to a pilular consistence"—(*U. S. P.*).

Description, Medical Uses, and Dosage.—Extract of black cohosh is black in color, and is representative of the crude drug. It is suggested that a menstruum containing $\frac{1}{2}$ part water, will furnish as reliable a preparation. The extract of black cohosh possesses all the virtues of the root, and in nervous derangements, as *chorea*, *epilepsy*, etc., is much superior to the resin from the root in efficiency. It is decidedly more narcotic and antispasmodic than this resin. It makes extensive and successful use of it in *epilepsy*, *chorea*, *delirium tremens*, (which I combine it with quinine), *nervous excitability*, and many *spasmodic* affections. Persons subject to *cramps* will be speedily and permanently relieved by the employment of this extract combined with the extract of cramp bark. The extract of black cohosh may be used in all instances where the employment of the root is indicated. The dose is from 1 to 5 or 10 grains, 3 times a day.

EXTRACTUM CIMICIFUGÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF CIMICIFUGA

Preparation.—"Cimicifuga, in No. 60 powder, one thousand grammes (Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. oz., 391 Ml.]. Moisten the powder with two hundred and fifty cubic centimeters (250 Cc.) [8 fl. oz., 218 Ml.] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the cimicifuga is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl. oz., 208 Ml.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters [33 fl. oz., 391 Ml.]"—(*U. S. P.*).

Description, Medical Uses, and Dosage.—This preparation has a darkish-brown color like laudanum, is transparent, and possesses the bitter, agreeable taste of the root in a marked degree. Its flavor may be improved by the addition of white sugar, and a small portion of some aromatic essence at the time of taking it. Fluid extract of black cohosh possesses tonic, narcotic, antispasmodic, alterative, and emmenagogue properties. It may be used with advantage in *neuralgia*, *scrofula*, *sypilis*, *amenorrhœa*, *dysmenorrhœa*, *chorea*, and in all cases in which the root is indicated. The dose is from 10 to 60 minims.

EXTRACTUM CINCHONÆ (U. S. P.)—EXTRACT OF CINCHONA

SYNONYM: *Extract of calisaya bark.*

Preparation.—"Cinchona, in No. 60 powder, one thousand grammes (Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, three thousand cubic centimeters

Cc.) [101 fl̄, 212 M]; water, one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]; diluted alcohol, a sufficient quantity. Mix the alcohol and water, and, having moistened the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 M] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then diluted alcohol, until four thousand cubic centimeters (4000 Cc.) [8 O, 7 fl̄, 122 M] of the tincture are obtained, or the cinchona is exhausted. Distill off the alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—If the directions above given are closely followed, and too great a degree of heat avoided, a representative preparation will result. Extract of cinchona has the bitterness of the bark, a red-brown color, and does not wholly dissolve in water. Its tendency to become tough in time may be prevented by incorporating with it while still warm, 10 per cent of glycerin. Its uses are those of cinchona, and the dose is from 10 to 30 grains.

EXTRACTUM CINCHONÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF CINCHONA.

SYNONYMS: *Fluid extract of yellow cinchona bark, Fluid extract of calisaya bark.*

Preparation.—"Cinchona, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, two hundred cubic centimeters (200 Cc.) [6 fl̄, 366 M]; alcohol, water, each, a sufficient quantity, to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Mix the glycerin with eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 M] of alcohol. Moisten the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 M] of the mixture, pack it firmly in a cylindrical percolator, and pour on the remainder of the menstruum. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, and, when the liquid in the percolator has disappeared from the surface, gradually pour on a mixture of alcohol and water, made in the proportion of eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 M] of alcohol to two hundred cubic centimeters (200 Cc.) [6 fl̄, 366 M] of water, and continue the percolation until the cinchona is exhausted. Reserve the first seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 M] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough of a mixture of alcohol and water, using the same proportions as before, to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]"—(U. S. P.).

Description, Medical Uses, and Dosage.—This preparation contains all the alkaloidal principles of cinchona, and has a rich deep red-brown color. It is moderately thin and translucent, and possesses the bitterness and astringency of the bark. Its properties are those of cinchona, and it may be used alone or in combination with other agents. Used chiefly as a tonic in doses of $\frac{1}{2}$ to 1 fluid drachm.

EXTRACTUM COCÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF COCA.

SYNONYMS: *Extractum erythroxylī fluidum (U. S. P., 1880), Fluid extract of erythroxylon.*

Preparation.—"Coca, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity, to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Moisten the powder with four hundred and fifty cubic centimeters (450 Cc.) [15 fl̄, 104 M] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol

to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the coca is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Coca*). Fluid extract of coca is of a deep greenish-brown or olive-brown color. It has the bitterness and astringency of the leaves, as well as the feebly aromatic, tea-like flavor. Its odor is slight. Dose, 10 to 60 minims.

EXTRACTUM COFFEE VIRIDIS FLUIDUM (N. F.)—FLUID EXTRACT OF GREEN COFFEE.

Preparation.—*Formulary number*, 148: "From the commercial, unroasted seeds of *Coffea arabica*, Linné (*Coffee*). *Process B* (see F. 135). No. 20 powder. *Menstruum I*: Alcohol, two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄]; water, six hundred and eighty-five cubic centimeters (685 Cc.) [23 fl̄, 78 m̄]; glycerin, sixty-five cubic centimeters (65 Cc.) [2 fl̄, 95 m̄]. *Menstruum II*: Alcohol, 1 volume; water, 3 volumes. *Note*.—It is recommended that the best quality of either of the commercial varieties known as Java or Mocha coffee be employed for this preparation"—(Nat. Form.).

Medical Uses and Dosage.—(See *Coffea*). Dose, 5 to 60 minims.

EXTRACTUM COFFEE TOSTÆ FLUIDUM (N. F.)—FLUID EXTRACT OF ROASTED COFFEE.

Preparation.—*Formulary number*, 149: "From the commercial roasted seeds of *Coffea arabica*, Linné (*Coffee*). *Process B* (see F. 135). No. 20 powder. *Menstruum I*: Alcohol, two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄]; water, six hundred and eighty-five cubic centimeters (685 Cc.) [23 fl̄, 78 m̄]; glycerin, sixty-five cubic centimeters (65 Cc.) [2 fl̄, 95 m̄]. *Menstruum II*: Alcohol, 1 volume; water, 3 volumes. *Note*.—See the note to the preceding"—(Nat. Form.).

Medical Uses and Dosage.—(See *Coffea*). Dose, 5 to 60 minims.

EXTRACTUM COLCHICI RADICIS (U. S. P.)—EXTRACT OF COLCHICUM ROOT.

SYNONYMS: *Extractum colchici aceticum* (U. S. P., 1870), *Acetic extract of colchicum*.

Preparation.—"Colchicum root, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; acetic acid, three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄]; water, a sufficient quantity. Mix the acetic acid with fifteen hundred cubic centimeters (1500 Cc.) [50 fl̄, 346 m̄] of water, and, having moistened the powder with five hundred cubic centimeters (500 Cc.) [16 fl̄, 435 m̄] of the mixture, pack it moderately in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then water, until the colchicum root is exhausted. Evaporate the percolate in a porcelain vessel, by means of a water-bath, at a temperature not exceeding 80° C. (176° F.), to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a soft extract, bitter to the taste and brown in color. Its solution in water is somewhat turbid. Uses those of colchicum, and employed mostly in pills. Dose, $\frac{1}{4}$ to 2 grains.

EXTRACTUM COLCHICI RADICIS FLUIDUM (U. S. P.)—FLUID EXTRACT OF COLOCHICUM ROOT.

Preparation.—“Colchicum root, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 m̄] of alcohol with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of water, and, having moistened the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the colchicum root is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Colchicum*). Fluid extract of colchicum root has a deep brownish-red color and a bitter taste. Dose, 1 to 8 minims.

EXTRACTUM COLOCHICI SEMINIS FLUIDUM (U. S. P.)—FLUID EXTRACT OF COLOCHICUM SEED

Preparation.—Colchicum seed, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity, to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 m̄] of alcohol with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of water, and, having moistened the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the colchicum seed is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Medical Uses and Dosage.—(See *Colchicum*). Dose, 1 to 8 minims.

EXTRACTUM COLOCYNTHIDIS (U. S. P.)—EXTRACT OF COLOCYNTH.

Preparation.—“Colocynth, dried, and freed from the seeds, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity. Reduce the colocynth to a coarse powder by grinding or bruising, and macerate it in thirty-five hundred cubic centimeters (3500 Cc.) [118 fl̄, 167 m̄] of diluted alcohol for 4 days, with occasional stirring; then express strongly and strain through flannel. Pack the residue, previously broken up with the hands, firmly in a cylindrical percolator, cover it with the strainer, and gradually pour diluted alcohol upon it until the tincture and expressed liquid, mixed together, measure five thousand cubic centimeters (5000 Cc.) [10 O, 9 fl̄, 33 m̄]. Distill off the alcohol from the mixture by means of a water-bath; evaporate the residue to dryness, and reduce the dry mass to powder. Extract of colocynth should be kept in well-stoppered bottles”—(U. S. P.).

Medical Uses and Dosage.—Used chiefly in preparing the compound extract. As water extracts a large amount of mucilaginous and other inert material, the proportion of water should never be greater than that above directed. This extract is laxative and cathartic, according to the dose employed. Dose, from $\frac{1}{2}$ to 2 grains.

EXTRACTUM COLOCYNTHIDIS COMPOSITUM (U. S. P.) COMPOUND EXTRACT OF COLOCYNTH.

Preparation.—“Extract of colocynth, one hundred and sixty grammes (160 Gm.) [5 ozs. av., 282 grs.]; purified aloes, five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; cardamom, in No. 60 powder, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; resin of scammony, in fine powder, one hundred and forty grammes (140 Gm.) [4 ozs. av., 411 grs.]; soap, dried and in coarse powder, one hundred and forty grammes (140 Gm.) [4 ozs. av., 411 grs.]; alcohol, one hundred cubic centimeters (100 Cc.) [3 fl \bar{z} , 183 M]. Heat the aloes, contained in a suitable vessel, on a water-bath, until it is completely melted; then add the alcohol, soap, extract of colocynth, and resin of scammony, and heat the mixture at a temperature not exceeding 120° C. (248° F.), until it is perfectly homogeneous, and a thread taken from the mass becomes brittle when cool. Then withdraw the heat, thoroughly incorporate the cardamom with the mixture, and cover the vessel until the contents are cold. Finally, reduce the product to a fine powder. Compound extract of colocynth should be kept in well-stoppered bottles”—(U. S. P.). This is the standard cathartic of tradition and authority. Devised before the discovery of resin of podophyllum, the expensive drug scammony, was introduced into it. Experience seems to demonstrate that not only may it be economically replaced by this resin, but with advantage to the effectiveness of the resultant extract.

Medical Uses and Dosage.—Compound extract of colocynth is an active cathartic, and may be employed in all cases where catharsis is indicated. From the difficulty with which pure scammony can be obtained in this country, I would suggest as a substitute for it in the above formula, resin of *podophyllum*, in powder, *one-fourth* the amount of scammony resin named, and which, by no means, lessens the value or efficiency of the preparation. If a little good extract of *hyoscyamus* or one part of *capsicum*, or of oil of cloves, be added to the formula, it will tend very much to prevent any griping or other unpleasant action. This compound extract may be especially used in *constipation*, *torpor of the liver*, *headache*, etc., in doses varying from 3 to 20 grains (J. King).

EXTRACTUM CONDURANGO FLUIDUM.—FLUID EXTRACT OF CONDURANGO.

Preparation.—Take of condurango bark, in moderately fine powder, 16 troy ounces; of a menstruum of alcohol, 3 parts; water, 2 parts (by measure), a sufficient quantity. Moisten the condurango with 6 fluid ounces of the menstruum. Cork tightly in a wide-mouth bottle, and permit the mixture to stand an hour in a warm situation. Then introduce it into a cylindrical percolator, 3 inches in diameter, previously prepared for percolation, according to directions given on page 756, and press moderately. Cover the surface of the powder with a circular piece of filtering paper, held in position with a few fragments of glass or marble, and add fresh menstruum until the percolate appears at the exit. Then cork the exit tightly, cover the percolator, and place it in a warm situation. After 24 hours, loosen the cork, and permit the percolate to pass as fast as it will drop, without running in a stream, until 4 fluid ounces are obtained. Again close the exit, macerate 24 hours, and, in a manner like unto the preceding, draw 4 fluid ounces of percolate. Repeat the maceration, and, in a like manner, draw a third portion of 4 fluid ounces. Reserve and mix the 3 percolates, then continue the percolation until 8 fluid ounces are obtained. Evaporate this latter portion until reduced to the measure of 2 fluid ounces, and mix with the reserved 12 fluid ounces. The surface of the powder must be constantly covered with the menstruum from the commencement, and until the end of the process of percolation.

Description, Medical Uses, and Dosage.—(See *Condurango*). Fluid extract of *condurango* is dark, reddish-brown in color, of an aromatic taste, slight odor, and, as thus prepared, represents very nearly the quality of drug employed, troy ounce to each fluid ounce of the finished extract. Dose, 10 to 30 minims.

EXTRACTUM CONII (U. S. P.)—EXTRACT OF CONIUM.

SYNONYMS: *Extractum conii alcoholicum* (U. S. P., 1880), *Alcoholic extract of hemlock fruit*.

Preparation.—"Conium, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; acetic acid, twenty cubic centimeters (20 Cc.) [325 Ml.]; diluted alcohol, a sufficient quantity. Mix the acetic acid with nine hundred and eighty cubic centimeters (980 Cc.) [33 fl. 3, 166 Ml.] of diluted alcohol, and, having moistened the powder with three hundred cubic centimeters (300 Cc.) [10 fl. 3, 69 Ml.] of the mixture, pack it firmly in a cylindrical percolator. Then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until three thousand cubic centimeters (3000 Cc.) [101 fl. 3, 212 Ml.] of tincture are obtained, or until the conium is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl. 3, 208 Ml.] of the percolate, and evaporate the remainder, in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to one hundred cubic centimeters (100 Cc.) [3 fl. 3, 183 Ml.], mix this with the reserved portion, and evaporate, at or below the above-mentioned temperature, to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—This extract was formerly prepared from the leaves, which gave a variable and uncertain product. As now prepared from the seeds, it is the most variable of the class of extracts. The acetic acid is added to fix the coniine, as it is thought to retard the changes which the product is liable to from heat and exposure. This extract is narcotic, and may be used in all cases where its peculiar influence is desired. The dose is from $\frac{1}{8}$ grain to 1, 2, or 3 grains, 2 or 3 times a day.

EXTRACTUM CONII FLUIDUM (U. S. P.)—FLUID EXTRACT OF CONIUM.

SYNONYMS: *Fluid extract of conium seeds*, *Fluid extract of conium fruit*, *Extractum conii fructus fluidum* (U. S. P., 1870).

Preparation.—"Conium, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; acetic acid, twenty cubic centimeters (20 Cc.) [325 Ml.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 Ml.]. Mix the acetic acid with nine hundred and eighty cubic centimeters (980 Cc.) [33 fl. 3, 166 Ml.] of diluted alcohol, and, having moistened the powder with three hundred cubic centimeters (300 Cc.) [10 fl. 3, 69 Ml.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the conium is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl. 3, 208 Ml.] of the percolate, and evaporate the remainder, in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 Ml.]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Conium*). This process is based upon that of Prof. W. Procter, Jr. (*Proc. Amer. Pharm. Assoc.*, 1859, pp. 271-2; see also *Amer. Disp.*, 15th ed., p. 993). Prof. Procter remarks that in each of the drugs (*ergot*, *conium*, *lobelia*) there exists an alkaloid united with an organic

acid, as a salt, which is so unstable in its nature, as to be with each drug decomposed by the ebullition of its solution; this tendency is almost completely controlled by acetic acid, at a temperature below 65.5° C. (150° F.), and a unexceptionable fluid extract is thus obtained. Fluid extract of conium is brownish-green color, and the characteristic odor of conium, which is increased by the addition of caustic potash. It contains the active properties of hemlock in a concentrated form, and may be given in doses of from 3 to 10 minims, according to the effects produced.

EXTRACTUM CONVALLARIÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF CONVALLARIA.

SYNONYM: *Fluid extract of lily of the valley.*

Preparation.—"Convallaria, in No. 60 powder, one thousand grammes (Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 Ml.]. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl. 3, 252 Ml.] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid has dropped from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, continually adding diluted alcohol, until the convallaria is exhausted. Reserve eight hundred cubic centimeters (800 Cc.) [27 fl. 3, 25 Ml.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved percolate, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 Ml.]"—(U. S. P.).

Medical Uses and Dosage.—This represents the virtues of the dried convallaria, but the fresh rhizome is employed in Eclectic medicine. Dose, 1 to 10 minims.

Related Preparation.—EXTRACTUM CONVALLARIÆ FLORUM FLUIDUM (N. F.)—FLUID EXTRACT OF CONVALLARIA FLOWERS.—*Formulary number, 150:* "From the flowers of *Convallaria majalis* (Lily of the valley). *Process A* (see F. 135). No. 40 powder. *Menstruum:* Diluted alcohol (Nat. Form.). This preparation is scarcely known, and might well be dropped.

EXTRACTUM COPTIS FLUIDUM (N. F.)—FLUID EXTRACT OF COPTIS.

Preparation.—*Formulary number, 151:* "From the rhizome and roots of *Coptis trifolia*, Salisbury (Goldthread). *Process A* (see F. 135). No. 40 powder. *Menstruum:* Diluted alcohol"—(Nat. Form.). This preparation is seldom prepared, and possesses no qualities that commend it in any way above hydrastis.

Medical Uses and Dosage.—(See *Coptis*). Dose, 5 to 60 minims.

EXTRACTUM CASTANÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF CASTANEA.

SYNONYM: *Fluid extract of chestnut leaves.*

Preparation.—"Castanea, in No. 30 powder, one thousand grammes (Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl. 3, 183 Ml.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 Ml.]. Pour five thousand cubic centimeters (5000 Cc.) [10 O, 9 fl. 3, 33 Ml.] of boiling water upon the powder, and macerate for 2 hours, then express the liquid, transfer the residue to a percolator, and pour water upon it until the powder is exhausted. Evaporate the liquids, on a water-bath, to two thousand cubic centimeters (2000 Cc.) [66 fl. 3, 301 Ml.], allow this to cool, and add six hundred cubic centimeters (600 Cc.) [18 fl. 3, 138 Ml.] of alcohol. When the insoluble matter has subsided, separate the liquid, filter the remainder, evaporate the united liquids to seven hundred cubic centimeters (700 Cc.) [23 fl. 3, 321 Ml.], allow this to cool, add the glycerine.

enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Castanea*). This fluid extract is powerfully, but agreeably astringent in taste, and has a red-brown color. The boiling water readily extracts the active virtues of the leaves, and the extract is finally preserved by the addition of alcohol and $\frac{1}{4}$ part of glycerin. In our opinion the infusion of the leaves, made fresh, is superior to this or any other pharmaceutical preparation of chestnut leaves. Dose, $\frac{1}{2}$ to 2 fluid drachms.

EXTRACTUM CORNUS.—EXTRACT OF CORNUS.

SYNONYM: *Extract of dogwood.*

Preparation.—Exhaust coarsely powdered dogwood bark with alcohol, water, of each, a sufficient quantity, proceeding in the same manner as explained for the preparation of Alcoholic Extracts, on page 758.

Medical Uses and Dosage.—Extract of dogwood is tonic and antiperiodic and may be successfully used as a substitute for quinine, in many cases. It will be found useful in *dyspepsia*, *debility of the stomach*, and as a tonic in *dropsical affections* after the water has been evacuated. The dose is from 1 to 5 grains, 3 times a day.

EXTRACTUM CORNUS FLUIDUM.—FLUID EXTRACT OF CORNUS.

SYNONYM: *Fluid extract of dogwood.*

Preparation.—Take of dogwood bark, in coarse powder, 16 troy ounces; alcohol, 76 per cent, 4 pints; white sugar, 6 troy ounces; water, a sufficient quantity. Moisten the bark thoroughly with alcohol and let it stand 24 hours; then transfer it to a percolator, and gradually add the rest of the alcohol, returning a little of the first that passes till it runs clear. Reserve, by itself, of the first running, 4 fluid ounces; evaporate the remaining alcoholic tincture that comes through to 4 fluid ounces, and likewise set it aside. To the powder in the percolator add gradually cold water, a sufficient quantity, until the liquid that passes is but slightly impregnated with the properties of the dogwood; evaporate this latter solution to $\frac{1}{2}$ pint, then add the sugar, continue the evaporation until the syrup is reduced to 8 fluid ounces, and while warm, mix in the reserved tincture and extract, and make 1 pint of fluid extract.

Medical Uses and Dosage.—Fluid extract of dogwood is tonic, stimulant, and slightly astringent. It may be used in all cases where tonics are indicated, and will be found beneficial in *female debility*, *leucorrhœa*, etc. The dose is from $\frac{1}{2}$ to 2 fluid drachms.

EXTRACTUM CORYDALIS.—EXTRACT OF CORYDALIS.

SYNONYM: *Extract of turkey corn.*

Preparation.—Exhaust coarsely powdered root of turkey corn, with alcohol, water, each, a sufficient quantity, proceeding in the same manner as explained for the preparation of Alcoholic Extracts, on page 758.

Medical Uses and Dosage.—This extract is tonic and alterative, and may be employed in all cases where tonics are indicated. It is useful in all *scrofulous affections*; and in *syphilitic diseases*, both primary and secondary, it will be found among our most efficient agents. The dose is from 1 to 5 grains, 3 times a day (J. King).

EXTRACTUM CORYDALIS FLUIDUM (N. F.).—FLUID EXTRACT OF CORYDALIS.

Preparation.—*Formulary number, 154:* "From the tubers of *Dicentra canadensis*, De Candolle (*Turkey corn*). *Process A* (see F. 135). No. 60 powder. *Menstruum:* Alcohol, 3 volumes; water, 1 volume"—(Nat. Form.).

Medical Uses and Dosage.—(See *Corydalis*).

EXTRACTUM COTO FLUIDUM.—FLUID EXTRACT OF COTO.

Preparation.—Take of coto bark, in very fine powder, 16 troy ounces; alcohol, a sufficient quantity. Moisten the coto with 6 fluid ounces of alcohol. Cork tightly in a wide-mouth bottle, and permit the mixture to stand an hour in a warm situation. Then introduce it into a cylindrical percolator, 3 inches in diameter, previously prepared for percolation, according to directions given on page 756, and press very firmly. Cover the surface of the powder with a circular piece of filtering paper held in position with a few fragments of glass or marble, and add alcohol until the percolate appears at the exit. Then cork the exit tightly; cover the percolator, and place it in a warm situation. After 24 hours, loosen the cork, and permit the percolate to pass as fast as it will drop, without running in a stream, until 4 fluid ounces are obtained. Again close the exit, macerate 24 hours, and, in a manner like unto the preceding, draw 4 fluid ounces of percolate. Repeat the maceration, and, in like manner, draw a third portion of 4 fluid ounces. Reserve, and mix the three percolates; then continue the percolation until 8 fluid ounces are obtained. Evaporate this latter portion until reduced to the measure of 2 fluid ounces, and mix with the reserved 12 fluid ounces. The surface of the powder must be constantly covered with alcohol from the commencement, and until the end of the process of percolation.

Description, Medical Uses, and Dosage.—Fluid extract of coto is of a reddish color, possesses an aromatic odor and a hot taste, followed by a numbness of the tongue, and, as thus prepared, it represents very nearly the quality of drug employed, troy ounce to each fluid ounce of the finished extract. A mixture of alcohol and water will produce a much darker fluid extract; but alcohol is the best solvent for the characteristic medicinal principles of the drug, and the coloring matter observed in the aqueous extract is undesirable. The addition of water to the menstruum also renders the finished extract more prone to precipitation.

**EXTRACTUM CUBEBAE FLUIDUM (U. S. P.)—FLUID
EXTRACT OF CUBEBA.**

Preparation.—“Cubeba, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with two hundred cubic centimeters (200 Cc.) [6 fl̄, 366 m̄] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the cubeba is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a translucent, dark or olive-green fluid having the taste and odor of cubeba. It contains the resin and most of the essential oil. Formerly the oleoresin, made by means of ether, according to a process of Prof. Procter (*Proc. Amer. Pharm. Assoc.*, 1859, pp. 272–3), was prepared and sold as fluid extract of cubeba. Fluid extract of cubeba possesses the virtues of cubeba, and may be given in the dose of from 10 to 30 minims, in water, hydro-alcoholic solution, emulsion, or in capsules, and repeated 3 times a day.

**EXTRACTUM CUSO FLUIDUM (U. S. P.)—FLUID
EXTRACT OF KOUSSO.**

SYNONYMS: *Extractum brayeræ fluidum* (Pharm., 1880), *Extractum koso fluidum*; *Fluid extract of brayera*.

Preparation.—“Koussou, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity to make one thousand

cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the kousso is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate. Distill off the alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a dark, brown-green fluid possessing a disagreeably bitter, acrid taste. It is a remedy for *tapeworm*, but the large doses necessary contain an objectionable quantity of alcohol. The dose has been stated as $\frac{1}{2}$ fluid drachm to 1 fluid ounce. More than $\frac{1}{2}$ fluid ounce, should not, however, be prescribed.

EXTRACTUM CYPRIPEDEII.—EXTRACT OF CYPRIPEDIUM.

SYNONYM: *Extract of yellow ladies'-slipper.*

Preparation.—Exhaust coarsely powdered yellow ladies'-slipper root, with alcohol, water, each, a sufficient quantity, proceeding in the same manner as explained for the preparation of Alcoholic Extracts, on page 758.

Medical Uses and Dosage.—This extract is tonic and antispasmodic, and may be used to fulfil all the indications of the crude root in *hysteria*, *chorea*, *nervous headache*, and *nervous irritability*. It may be, in many cases, advantageously combined with the alcoholic extract of scullcap. Its dose is from 1 to 5 grains 2 or 3 times a day.

EXTRACTUM CYPRIPEDEII FLUIDUM (U. S. P.)—FLUID EXTRACT OF CYPRIPEDIUM.

Preparation.—“Cypripedium, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the cypripedium is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a deep, reddish-brown fluid fully representing cypripedium. Fluid extract of cypripedium is tonic, nerveine, and antispasmodic, and may be beneficially employed in *chorea*, *hysteria*, *nervous headache*, and all cases of *nervous irritability* and *excitability*. A few drops of oil of anise may be added to it to improve its flavor. The dose is from 10 to 30 minims 3 times a day.

EXTRACTUM DIGITALIS (U. S. P.)—EXTRACT OF DIGITALIS.

SYNONYM: *Extractum digitalis alcoholicum*

Preparation.—“Digitalis, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity. Mix six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 m̄] of alcohol with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of the

mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until three thousand cubic centimeters (3000 Cc.) [101 fl̄, 212 M] of tincture are obtained, or the digitalis is exhausted. Distill off the alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, at a temperature not exceeding 50° C. (122° F.) to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Digitalis*). This is a greenish-brown extract, and, as with conium, an excessive heat must be avoided in its preparation. It has not found much favor among therapeutists. The dose is $\frac{1}{2}$ grain gradually increased to 1 grain. It should be remembered that digitalis acts slowly, and the extract must not be pushed too rapidly.

EXTRACTUM DIGITALIS FLUIDUM (U. S. P.)—FLUID EXTRACT OF DIGITALIS.

Preparation.—"Digitalis, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Mix six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 M] of alcohol with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 M] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 M] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the digitalis is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 M] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract, dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]"—(U. S. P.).

Description, Medical Uses, and Dosage.—This produces a dark, greenish-brown, or greenish-black, fluid extract, which is likely to deposit a sediment on standing. The dose is from $\frac{1}{2}$ to 2 minims.

EXTRACTUM DIOSCOREÆ.—EXTRACT OF DIOSCOREA.

SYNONYM: *Dioscorein*.

Preparation.—Make a saturated tincture of the powdered root of *Dioscorea villosa*, and filter; add the tincture to its weight of water, and carefully distill off the alcohol; the resinoid principle will be left behind in the water, collect, dry, and pulverize it. This is the original formula as named to me by Mr. Wm. S. Merrell, for its preparation, about the time of its introduction to the profession.

History and Description.—The profession is indebted to Mr. Wm. S. Merrell for the preparation and introduction of this agent; it having been first prepared by him in the winter of 1852-3. Dr. T. L. A. Greve states that the article which has been sold for some years past, and is still sold under the name of *Dioscorein*, is the alcoholic extract of the root, dried and powdered (King). This statement of Dr. Greve is in accordance with our views, and we believe that the term *Dioscorein* is improper. This preparation and a few others of similar composition are retained in the class of extracts which they occupied in preceding editions of this publication. (See remarks on resinoids and concentrations under *Resina Podophylli*).

Medical Uses and Dosage.—Extract of dioscorea possesses the properties of the crude root in an eminent degree, and is undoubtedly as much a specific in *bilious colic*, as quinine is in intermittents. In a severe case of bilious colic, pro-

nounced past hope by several physicians, 4 grains rubbed up with a tablespoonful of brandy afforded prompt relief, and a repetition of the dose, in about 20 minutes from the time of taking the first, effected a cure. In ordinary cases, 1 or 2 grains of this extract may be administered every 5, 10, or 20 minutes, according to the urgency of the case. In *flatulence, borborygmi*, etc., it may be advantageously combined with ginger, extract of aletris, or of asclepias; in many forms of *uterine disease* its union with resin of black cohosh, oleoresin of senecio, resin of blue cohosh, etc., will prove very useful; and it may be combined with the extract of *Cornus sericea*, to overcome the *nausea and vomiting of pregnant females*. In *cramp of the stomach*, or *painful spasmodic affections of the bowels*, a pill or powder composed of equal parts of extract of dioscorea, resin of blue cohosh, and extract of high cranberry bark, will be found a remedy of great value, as well as in *after-pains*: the mixture should be given in 3 or 4-grain doses, and repeated every half hour or hour. It is strictly an American remedy, of great value. Dose, from 1 to 4 grains, repeated as circumstances require (J. King).

EXTRACTUM DULCAMARÆ.—EXTRACT OF DULCAMARA.

SYNONYM: *Extract of bitter-sweet.*

Preparation.—Exhaust the bark of the root and twigs of bitter-sweet, coarsely powdered, with alcohol, water, each, a sufficient quantity, proceeding in the same manner as explained for the preparation of Alcoholic Extracts, on page 758.

Medical Uses and Dosage.—The extract of bitter-sweet possesses the active properties of the plant, and may be beneficially employed in *scrofula, syphilis, cutaneous diseases*, and wherever the plant is indicated. The dose is from 2 to 10 or 20 grains, 3 times a day.

EXTRACTUM DULCAMARÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF DULCAMARA.

SYNONYM: *Fluid extract of bitter-sweet.*

Preparation.—“Dulcamara, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder, and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the dulcamara is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Dulcamara*). A thickish, deep-brown fluid, representing the virtues of bitter-sweet. Dose, 10 to 60 minims, well diluted with water.

EXTRACTUM EPIGÆÆ FLUIDUM.—FLUID EXTRACT OF EPIGÆÆ.

SYNONYM: *Fluid extract of trailing arbutus.*

Preparation.—Take of the recently dried leaves of *Epigæa repens*, in coarse powder, 16 troy ounces; alcohol, a sufficient quantity; diluted alcohol, a sufficient quantity. Moisten the leaves thoroughly with some of the alcohol, and let it stand for 24 hours; then transfer to a percolator, and gradually add the rest of the alcohol, returning a little of the first that passes, until it runs clear. Reserve, by itself, of the first running, 12 fluid ounces; then add gradually a sufficient quantity of diluted alcohol, until the liquid that passes is but slightly impregnated

with the taste of the leaves; evaporate this latter solution to 4 fluid ounces, then mix in the reserved tincture and make 1 pint of fluid extract. This fluid extract is subject to disintegration, the product being a gelatinous pectin-like magma or mush.

Medical Uses and Dosage.—The fluid extract of trailing arbutus possesses diuretic and astringent properties, and will be found superior to the preparations of *uva ursi*, *buchu*, etc., in *gravel*, and various other disorders of the urinary organs. It may likewise be used in *chronic diarrhœa* and *summer complaint*. The dose is 1 fluid drachm, 3 or 4 times a day (J. King).

EXTRACTUM ERGOTÆ (U. S. P.).—EXTRACT OF ERGOT.

SYNONYMS: *Ergotin*, *Extractum hæmostaticum*.

Preparation.—“Fluid extract of ergot, one hundred and fifty cubic centimeters (150 Cc.) [5 fl̄3, 35 M]. Evaporate the fluid extract of ergot in a porcelain capsule, by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), constantly stirring, until it is reduced to a pilular consistence”—(U. S. P.).

The *British Pharmacopœia* process is based on Bonjean's. It consists in evaporating to a syrupy consistence 4 fluid ounces of liquid ergot (prepared chiefly with water), adding 4 fluid ounces of rectified spirit, filtering, and evaporating to a soft extract. This corresponds with *Bonjean's Ergotin*.

Description, Medical Uses, and Dosage.—(See *Ergota*). The U. S. P. process originated with Dr. Edward R. Squibb. The product is essentially that known as *Ergotin*. It is a pale-brown, or reddish-brown extract, wholly soluble in diluted alcohol, insoluble in cold alcohol, and dissolves in water, with the exception of a slight residue, yielding a garnet-red solution. Dose, 3 to 20 grains. It may be given hypodermatically by dissolving 5 parts in 7 parts each of water and glycerin, and filtering the solution.

EXTRACTUM ERGOTÆ FLUIDUM (U. S. P.).—FLUID EXTRACT OF ERGOT.

Preparation.—“Ergot, recently ground and in No. 60 powder, one thousand grammes (1000 Gm) [2 lbs. av., 3 ozs., 120 grs.]; acetic acid twenty cubic centimeters (20 Cc.) [325 M]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M]. Mix the acetic acid with nine hundred and eighty cubic centimeters (980 Cc.) [33 fl̄3, 66 M] of diluted alcohol, and having moistened the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄3, 69 M] of the mixture, pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the ergot is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄3, 356 M] of the percolate, and evaporate the remainder, in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M]”—(U. S. P.).

Description, Medical Uses, and Dosage.—This process gives a clear fluid, of a dark-brown color, somewhat red, possessing a taste like ergot, and developing the peculiar fishy smell of trimethylamine, when liquor potassæ is added to it. This process is essentially that of Prof. W. Procter, Jr., who recommended the use of an acid to fix the alkaloidal principles. Prof. Procter suggested another process wherein ether was employed, but this was subsequently discarded. The fluid extract may be used as a substitute for ergot in all cases. It is pleasant to the taste, is always ready for use, requires a small dose, and acts promptly without nausea. The dose is from $\frac{1}{2}$ to 4 fluid drachms. A fluid drachm is about equal to 2 doses of powdered ergot.

Related Preparation.—**FLUID ERGOT.** Prof. C. S. Hallberg commends the following fluid ergot: "Upon the investigations of Dragendorff, Podwissotzky, Blumberg, and others, having been made public, new processes were adopted for preparations that would conform to these theories. The writer constructed a formula for a preparation termed fluid ergot, in contradistinction to the official fluid extract. As this article has proved, during several years increasing use, its superiority over the ordinary fluid extract, and clinical experience sustained the views held in regard to it on theoretical grounds, the process for its preparation might be of interest. The powdered, purified ergot, prepared as above, is digested with twice its weight of water at 65.5° C. (150° F.), for 24 hours and expressed, the residue is again macerated in warm water for 12 hours. After settling, the expressed liquids are strained and evaporated separately, when both together measure one-half as much as the ergot employed. They are mixed and sufficient alcohol added to make the liquid of 25 per cent alcoholic strength, or one-third as much as the aqueous solution. After standing, the liquid is filtered and the gummy residue washed with so much 25 per cent alcohol as to make the filtered liquid measure three-fourths, or 75 per cent of the amount of the crude drug employed (volume for weight). To this glycerin is added to make the finished preparation represent the amount of crude ergot originally used (pint for pound). As will be seen, this preparation contains 18 per cent alcohol, rendering it unobjectionable for hypodermatic use. Fluid ergot is an opalescent, amber-colored liquid, possessing a peculiar musty odor. It remains pretty clear unless exposed for a long time to the light or atmosphere. It should, therefore, be kept in small, well-filled bottles in a cool, dark place" (*Amer. Jour. Pharm.*, 1883, p. 11).

EXTRACTUM ERIODICTYI FLUIDUM (U. S. P.)—FLUID EXTRACT OF ERIODICTYON.

SYNONYM: *Fluid extract of yerba santa.*

Preparation.—"Eriodictyon, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 8 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Mix eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 M̄] of alcohol with two hundred cubic centimeters (200 Cc.) [6 fl̄, 366 M̄] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 M̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the eriodictyon is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 M̄] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]"—(*U. S. P.*). According to our experience, this preparation should be made with official alcohol. The characteristic constituents of the drug are resinous and incompatible with water. This fluid extract was introduced by Parke, Davis & Co., and it was through their efforts that it attained its present popularity.

Description, Medical Uses, and Dosage.—(See *Eriodictyon*). The menstruum here employed fully extracts the virtues of yerba santa. Fluid extract of eriodictyon is dark brownish-green in color, and possesses the exact odor and taste of the plant, and, if made with alcohol 0.820, represents very nearly the quality of drug employed, troy ounce to each fluid ounce of the finished extract. It may be used to conceal the bitter taste of quinine. The dose ranges from 10 to 60 minims.

EXTRACTUM EUCALYPTI FLUIDUM (U. S. P.)—FLUID EXTRACT OF EUCALYPTUS.

Preparation.—"Eucalyptus, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lb. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 M̄] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 M̄] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 M̄] of the mixture, pack it firmly in a cylindrical percolator; then add

enough menstruum to saturate the powder, and leave a stratum above it; when the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the eucalyptus is exhausted. Reserve the first three hundred cubic centimeters (900 Cc.) [30 fl \bar{z} , 208 M.] of the percolate, and macerate the remainder to a soft extract; dissolve this in the reserved percolate, add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl \bar{z} , 391 M.]—(U. S. P.). We prefer the following:

“Take of eucalyptus leaves, in moderately fine powder, 16 troy ounces; alcohol, a sufficient quantity. Moisten the eucalyptus with 6 fluid ounces of alcohol. Cork tightly in a wide-mouth bottle, and permit the mixture to stand in a warm situation. Then introduce it into a cylindrical percolator, 3 inches in diameter, previously prepared for percolation, according to directions on page 756, and press very firmly. Cover the surface of the powder with a piece of filtering paper, held in position with a few fragments of glass, and add alcohol until the percolate appears at the exit. Then cork the percolator tightly; cover the percolator, and place it in a warm situation. After loosening the cork, and permit the percolate to pass as fast as it will drop, running in a stream, until 4 fluid ounces are obtained. Again cork the percolator, macerate 24 hours, and in a manner like unto the preceding, draw 3 fluid ounces of percolate. Repeat the maceration, and, in like manner, draw a third of 3 fluid ounces. Lastly, mix the 3 percolates. The surface of the powder must be constantly covered with alcohol from the commencement, and until the end of the process of percolation.”

Description, Medical Uses, and Dosage.—(See *Eucalyptus*). The color of eucalyptus is dark brownish-green, or green, in color, and possesses a strong odor of the leaves, and, as thus prepared, represents very nearly the strength of drug employed, troy ounce to each fluid ounce of the finished extract. In experience this preparation should be made with alcohol. Water is not in proper proportion to the amount present. We, therefore, supplement the above formula long established in our hands and published in the supplement to the last edition of this Dispensatory. Dose, 1 to 10 minims.

EXTRACTUM EUONYMI (U. S. P.).—EXTRACT OF EUONYMUS

SYNONYM: *Extract of wahoo.*

Preparation.—“Euonymus, in No. 80 powder, one thousand grains [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity. Six hundred cubic centimeters (600 Cc.) [20 fl \bar{z} , 138 M.] of alcohol with three hundred cubic centimeters (300 Cc.) [10 fl \bar{z} , 69 M.] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl \bar{z} , 252 M.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until three thousand cubic centimeters (3000 Cc.) [101 fl \bar{z} , 221 M.] of tincture are obtained or the euonymus is exhausted. Distill off the alcohol from the tincture by means of a water-bath, and having placed the residue in a glass capsule, evaporate it, on a water-bath, to a pilular consistence.”

Description, Medical Uses, and Dosage.—(See *Euonymus*). A yellowish-brown extract, the dose of which is from 1 to 5 grains.

EXTRACTUM EUPATORII.—EXTRACT OF EUPATORIUM

SYNONYM: *Extract of boneset.*

Preparation.—Exhaust the tops and leaves of boneset, bruised, with a sufficient quantity, proceeding in the same manner as explained for the preparation of Aqueous Extracts, on page 758.

Medical Uses and Dosage.—Extract of boneset is tonic and aperient, and may be given with advantage in convalescence from exhausting diseases, *intermittent fever, dyspepsia, debility of the digestive organs, and general debility*. The dose is from 1 to 10 grains 2 or 3 times a day.

EXTRACTUM EUPATORII FLUIDUM (U. S. P.)—FLUID EXTRACT OF EUPATORIUM.

SYNONYM: *Fluid extract of boneset.*

Preparation.—“Eupatorium, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the eupatorium is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄].”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Eupatorium*). This is a dark green-brown or brownish-red liquid representative of the herb. Dose, from 10 to 60 minims.

EXTRACTUM FERRI POMATUM (N. F.)—FERRATED EXTRACT OF APPLES.

SYNONYMS: *Ferri malas crudus, Crude malate of iron.*

Preparation.—*Formulary number, 156:* “Iron, in the form of fine, bright wire, and cut, twenty grammes (20 Gm.) [309 grs.]; ripe sour apples, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; water, a sufficient quantity. Convert the sour apples into a homogeneous pulp by pounding or grinding, and express the liquid portion. Then mix the latter with the iron in an enameled or porcelain vessel, macerate for 48 hours, and then apply the heat of a water-bath until no more bubbles of gas are given off, adding a little water from time to time to make up any loss by evaporation. Dilute the liquid with water to make it weigh one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.], and set it aside for a few days. Then filter, and evaporate the filtrate in the before-mentioned vessel, to a thick extract, which should be greenish-black, and should yield a clear solution with water. *Note.*—This preparation is inserted here with the title under which it is contained in the *German Pharmacopœia*. In some others it is called more correctly, *Extractum pomi (or pomorum) ferratum*”—(Nat. Form.).

Medical Uses and Dosage.—The uses and doses of this preparation are similar to those of citrate of iron and other ferruginous salts prepared with the common organic acids. It is a relic of European medieval medicine.

EXTRACTUM FRANGULÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF FRANGULA.

Preparation.—“Frangula, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix five hundred cubic centimeters (500 Cc.) [16 fl̄, 435 m̄] of alcohol with eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of water, and, having moistened the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid

begins to drop from the percolator, close the lower orifice, and, having covered the percolator, macerate for 48 hours. Then allow the percolate to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the frangula is exhausted. Reserve the first eight cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Frangula*). This preparation has a deep brownish-red color, and to the taste is both sweetish and bitter, an uncertain laxative. Dose, from 10 to 30 minims.

EXTRACTUM FUCI FLUIDUM (N. F.)—FLUID

EXTRACT OF FUCUS.

Preparation.—Formulary number, 157: “From the thallus of *Fucus* Linné (*Bladder-wrack*). Process A (see F. 135). No. 40 powder. Menstruum, 3 volumes; water, 1 volume”—(Nat. Form.).

Medical Uses and Dosage.—(See *Fucus*). Dose, 5 to 15 minims.

EXTRACTUM GALANGÆ FLUIDUM.—FLUID

EXTRACT OF GALANGAL.

Preparation.—Take of galangal root in fine powder, 16 troy ounces (454 gms.), a sufficient quantity. Moisten the galangal with 6 fluid ounces of alcohol, Cork tightly in a wide-mouth bottle, and permit the mixture to stand in a warm situation. Then introduce it into a cylindrical percolator, 31 centimeters in diameter, previously prepared for percolation, according to directions on page 756, and press very firmly. Cover the surface of the powder with a circular piece of filtering paper, held in position with a few fragments of marble, and add alcohol until the percolate appears at the exit. Then close the exit tightly; cover the percolator, and place it in a warm situation. After 24 hours loosen the cork, and permit the percolate to pass as fast as it will drop, running in a stream, until 4 fluid ounces are obtained. Again close the percolator, macerate 24 hours, and, in a manner like unto the preceding, draw 4 fluid ounces of percolate. Repeat the maceration, and, in like manner, draw a third portion of 4 fluid ounces. Reserve and mix the 3 percolates; then continue the percolation until 8 fluid ounces are obtained. Evaporate this latter portion until reduced to the measure of 2 fluid ounces, and mix with the reserved 12 fluid ounces. The surface of the powder must be constantly covered with alcohol from the commencement, and until the end of the process of percolation.

Description, Medical Uses, and Dosage.—Fluid extract of galangal has a reddish color, and possesses the exact odor and taste of the drug. It should be black, or thick, and if such is the case with any specimen, it may be inferred that the menstruum used was a mixture of alcohol and water, instead of alcohol alone. Alcohol freely extracts all the sensible properties of galangal, and the mixture of alcohol and glycerin is objectionable. (For uses, see *Galanga*). Dose, 5 to 30 minims.

EXTRACTUM GELSEMI FLUIDUM (U. S. P.)—FLUID

EXTRACT OF GELSEMIUM.

Preparation.—“Gelsemium, in No. 60 powder, one thousand grains (Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the per-

macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the gelsemium is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 M.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Gelsemium*). This fluid has a deep reddish-brown color and the bitter taste and characteristic odor of gelsemium. Eclectic physicians have no confidence in this or any other preparation made of dry gelsemium root. This, too, notwithstanding the assertions of some who claim that the alkaloid *gelsemine* dominates the drug, and is identical in both the fresh and the dry root. Dose, 1 to 5 minims.

EXTRACTUM GENTIANÆ (U. S. P.)—EXTRACT OF GENTIAN.

Preparation.—“Gentian, in No. 20 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; water, a sufficient quantity. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 M.] of water, and let it macerate for 24 hours; then pack it in a conical percolator, and gradually pour water upon it until the infusion passes but slightly imbued with the properties of the gentian. Reduce the liquid to three-fourths of its bulk by boiling, and strain; then, by means of a water-bath, evaporate to a pilular consistence”—(U. S. P.).

Description, Medical Uses, and Dosage.—Extract of gentian is a tenacious, shining, dark-brown or blackish product, very bitter to taste, but pleasant in odor. The principles are extracted by cold water, while the starch and pectin remain in the powder. By subsequent boiling the albuminous matter is separated. This extract is a tonic, and may be used wherever this indication is present, either alone or in conjunction with other tonics. The dose is from 1 to 10 grains.

EXTRACTUM GENTIANÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF GENTIAN.

Preparation.—“Gentian, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]. Moisten the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 M.] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the gentian is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 M.] of the percolate. Distill off the alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]—(U. S. P.).

Description, Medical Uses, and Dosage.—This extract has a dark reddish-brown color, is translucent and free from sediment, and transparent in thin strata. It possesses the taste and odor of gentian. Tonic, and may be given in doses of from $\frac{1}{2}$ to 1 fluid drachm, which represent $\frac{1}{2}$ to 1 drachm of gentian root. It may be variously combined with other agents to meet particular indications. For instance, should an aperient tonic, with antacid properties be desired, the following form may be used: Take of fluid extract of gentian, 2 fluid ounces; fluid extract of rhubarb, 2 fluid drachms; bicarbonate of potassium, 1 drachm; tincture of ginger, 2 fluid drachms. Mix. One fluid drachm of this mixture will be equal to about 40 grains of gentian, 6 of rhubarb, and 3 of bicarbonate of potassium. If a chalybeate tonic is desired, the following may be employed: Take of citrate of iron and quinine, 1 drachm; water, 6 fluid drachms; dissolve,

and add fluid extract of gentian, 2 fluid ounces. A fluid drachm of this mixture will represent about 45 grains of gentian, and 3 grains of citrate of iron and quinine (Wm. Procter, Jr.). Dose, 1 to 10 grains.

EXTRACTUM GENTIANÆ FLUIDUM COMPOSITUM. COMPOUND FLUID EXTRACT OF GENTIAN

Preparation.—Take of gentian, in coarse powder, 16 troy ounces; bitter orange peel, coriander seeds, of each, in coarse powder, 4 troy ounces; water, alcohol, each, a sufficient quantity. Macerate the gentian in 2½ pints of water for 12 hours, and introduce it into a percolator; allow the infusion to pass slowly, adding water at intervals until 5 pints of the liquid have passed. Evaporate this to 10 fluid ounces. Macerate the orange peel and coriander seeds in a mixture of 8 fluid ounces of alcohol, and 4 fluid ounces of water for 12 hours; introduce them into a percolator, and add gradually a sufficient quantity of diluted alcohol to displace 12 fluid ounces of tincture. Evaporate this to 6 fluid ounces by a gentle heat, 48.8° C. (120° F.), add it to the solution of gentian while hot, and strain. When finished, the fluid extract should measure a pint (Wm. Procter, Jr.). This formula can be simplified to advantage by mixing the powders and percolating in the usual manner.

Description, Medical Uses, and Dosage.—The compound fluid extract of gentian is a colored, thin, syrupy liquid. In the preparation of it I should prefer prickly ash berries to the coriander, both on account of their flavor and well-known influence on mucous tissues. Tonic and carminative, and may be given in doses of from ½ to 1 fluid drachm (J. King).

EXTRACTUM GERANIIL.—EXTRACT OF GERANIUM.

SYNONYM: *Geraniin*.

Preparation and History.—This article was formerly obtained by making a saturated tincture of the root of *Geranium maculatum*, filtering, distilling off a part of the alcohol, adding water to the residue, and evaporating to dryness. Many manufacturers have preferred to make it by evaporating an aqueous decoction of the root to dryness. Dr. T. L. A. Greve has given me the following statement: "Formerly, the dried and powdered resin of *Geranium maculatum* was sold under the name of *geraniin*, but was found to be nearly inert; the dried alcoholic extract was then substituted for it under the same name. By the ordinary mode of desiccating this extract, the red tannin, upon which the activity of the root principally, if not exclusively, depends, is almost wholly decomposed, and the resulting '*geraniin*' is quite worthless. A very good preparation may, however, be obtained, by evaporating a saturated tincture of the root to the consistence of thin syrup, then spreading this on glass plates with a brush, and when dry scraping off with a knife. The *geraniin* thus formed is in thin scales, very astringent, and possesses in a great degree, the active properties of the root." This latter is the article now used by the profession (J. King).

This is especially an American remedy. It was first prepared by Mr. Wm. S. Merrell, of Cincinnati, according to the first formula given above, who introduced it to the profession under the name of *Geraniin*; it was a black substance, forming a dark-brown glistening powder of a faint odor, somewhat like that of molasses, and an astringent, acidulous taste, leaving a flavor in the mouth somewhat resembling that of good green tea. Like many other concentrated agents, the name selected for it was entirely inappropriate (see *Concentrations*).

Medical Uses and Dosage.—Extract of geranium is a powerful astringent, and, unlike tannic acid in its action, does not cause a dryness of the mucous surfaces with which it comes in contact, but produces its therapeutical influence upon them with the continuance of their natural moisture. On this account and in connection with its not unpleasant taste, it may be substituted for tannic acid in many of the diseases in which this acid is employed. It may be employed in all instances where astringents are indicated. It has been found a superior

article, both in the first and second stages of *dysenteric diarrhœa*, *diarrhœa*, and *cholera morbus*. Equal parts of extracts of geranium and dioscorea, and resin of blue cohosh, will be found a valuable mixture in *diarrhœa* and *cholera morbus*, when much pain and flatulency are present; the mixture may be given in 6-grain doses to an adult, every 15 or 20 minutes, or as often as the urgency of the case may require. Extract of geranium will be found efficient in *hemorrhages*, *hematuria*, *menorrhagia*, *leucorrhœa*, *gleet*, *diabetes*, etc. In *colliquative diarrhœa* it answers an excellent purpose, either alone, or in combination with quinine. Externally, it may be applied to *ulcers*, and combined with alum and gum Arabic, it forms an excellent application to *bleeding wounds* and in *epistaxis*. Dose of the extract, from 1 to 5 grains or more, repeated as required; it may be given in syrup, molasses, gruel, water, or port wine.

EXTRACTUM GERANII FLUIDUM (U. S. P.)—FLUID EXTRACT OF GERANIUM.

Preparation.—"Geranium, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M̄]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Mix the glycerin with nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 M̄] of diluted alcohol, and, having moistened the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 M̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards diluted alcohol, until the geranium is exhausted. Reserve the first seven hundred cubic centimeters (700 Cc.) [23 fl̄, 321 M̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Geranium*). This is a deep reddish-brown fluid, with a powerfully astringent taste and but very little odor. It is subject to gelatinization in common with other preparations containing the so-called "red tannates," and it is not uncommon to find the extract change to a brown magma or mush. Dose, $\frac{1}{2}$ to 2 fluid drachms.

EXTRACTUM GLYCYRRHIZÆ (U. S. P.)—EXTRACT OF GLYCYRRHIZA.

SYNONYM: *Extract of liquorice.*

"The commercial extract of the root of *Glycyrrhiza glabra*, Linné (*Nat. Ord.*—*Leguminosæ*)"—(U. S. P.).

Source, History, and Description.—The black cylindrical sticks met with in commerce are an extract of liquorice root (*Extractum Glycyrrhizæ*), which is prepared in some of the southern European countries; they are in the form of hard, black cylinders, which are prepared by inspissating the decoction in copper kettles, till the mass is thick enough to become firm on cooling. Water slowly dissolves from $\frac{1}{2}$ to $\frac{1}{4}$ of it, alcohol only about $\frac{1}{4}$, and acquires an acrid taste, while the residuum is purely sweet, and entirely soluble in water.

The impure extract is in slightly compressed and cylindrical sticks, about 6 inches long, and from 9 to 12 lines in diameter, being enveloped in sweet bay leaves. The best kind is dark brownish-black, smooth, shining, brittle when cold, tough and flexible when warm, very sweet and soluble in water. It should be freed from impurities for internal use.

The U. S. P. describes extract of glycyrrhiza: "In flattened, cylindrical rolls, from 15 to 18 Cm. (6 to 7 inches) long, and from 15 to 30 Mm. ($\frac{1}{2}$ to $1\frac{1}{4}$ inch) thick; of a glossy black color. It breaks with a sharp, conchoidal, shining fracture, and

has a very sweet, peculiar taste. Not less than 60 per cent of it should be in cold water"—(U. S. P.). To purify liquorice, the crude extract is dissolved in water without boiling, the solution strained, and evaporated to the proper consistence. (See purified extract of liquorice.) If the water be boiled during the purification, much of the impurity may be taken up, which is not desirable. Large amounts of extract of liquorice, in the form of mass extract, are imported from the country for the use of tobaccoconists, who employ it to sweeten plug chewing tobacco.

EXTRACTUM GLYCYRRHIZÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF GLYCYRRHIZA.

SYNONYM: *Fluid extract of liquorice root.*

Preparation.—"Glycyrrhiza, in No. 40 powder, one thousand grammes (Gm.) [2 lbs. av., 3 ozs., 120 grs.]; ammonia water, fifty cubic centimeters [1 fl. 3, 332 M]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]. Mix the ammonia water with three hundred cubic centimeters (300 Cc.) [10 fl. 3, 69 M] of alcohol and six hundred and fifty cubic centimeters (650 Cc.) [21 fl. 3, 470 M] of water, and, having moistened the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl. 3, 332 M] of the mixture, pack it firmly in a cylindrical glass percolator; then add the menstruum to saturate the powder and leave a stratum above it. When it begins to drop from the percolator, close the lower orifice, and having covered the percolator, macerate for 48 hours. Then allow the percolation to proceed gradually adding, first, the remainder of the menstruum, and then a mixture of alcohol and water, made in the proportion of three hundred cubic centimeters (300 Cc.) [10 fl. 3, 69 M] of alcohol and six hundred and fifty cubic centimeters (650 Cc.) [21 fl. 3, 470 M] of water, until the glycyrrhiza is exhausted. Then, from the first seven hundred and fifty cubic centimeters (750 Cc.) [25 fl. 3, 111 M] of the percolate, and evaporate the remainder to a soft extract; dissolve the reserved portion, and add enough of the mixture of alcohol and water to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M]"—(U. S. P.).

Description and Medical Uses.—(See *Glycyrrhiza*). Unlike the preparation of the U. S. P., 1880, this fluid extract contains no glycerin, but some alcohol which renders the glycyrrhizin soluble, making the preparation sweeter and stronger. No ammonia is contained in the *Liquid extract of liquorice* (*Extractum Glycyrrhizæ Liquidum*) of the *British Pharmacopæia*. Fluid extract of glycyrrhiza is intended to facilitate the dispensing of extract of liquorice in cough mixtures and for concealing the bitter taste of quinine and quinine mixtures, and other unpleasantly bitter medicines. By adding fluid extract of liquorice to simple syrup (7 parts), a *syrup of liquorice* may be prepared, useful in the various prescribings of quinine. It must be remembered that mixtures of glycyrrhiza and liquorice produce unsightly precipitates, which must not be filtered. The extract of liquorice occasionally deposits its glycyrrhizin as a brown precipitate. When this occurs the addition of a small amount of ammonia water will dissolve it.

EXTRACTUM GLYCYRRHIZÆ PURUM (U. S. P.)—PURE EXTRACT OF GLYCYRRHIZA.

SYNONYMS: *Pure extract of liquorice, Extractum glycyrrhizæ depuratum, liquoritiz depuratus.*

Preparation.—"Glycyrrhiza, in No. 20 powder, one thousand grammes (Gm.) [2 lbs. av., 3 ozs., 120 grs.]; ammonia water, one hundred and fifty cubic centimeters (150 Cc.) [5 fl. 3, 35 M]; distilled water, a sufficient quantity to make the ammonia water with three thousand cubic centimeters (3000 Cc.) [100 fl. 3, 212 M] of distilled water, and, having moistened the powder with one hundred cubic centimeters (100 Cc.) [3 fl. 3, 391 M] of the menstruum, let it macerate for 24 hours. Then pack it moderately in a cylindrical glass percolator, and gradually pour upon it, first, the remainder of the menstruum, and then distilled

until the glycyrrhiza is exhausted. Lastly, evaporate the infusion, by means of a water-bath, to a pilular consistence"—(U. S. P.).

Description and Medical Uses.—(See *Glycyrrhiza*). This is a brown extract, possessing a pleasant sweet taste. It mixes clear with water. The object of the ammonia is to render the glycyrrhizin soluble. Care must be taken in its preparation, lest too great a heat should impart to it an empyreumatic flavor. It is used as a protective demulcent and lenitive in *laryngo-broncho-pulmonic affections*, but chiefly as an adjuvant in various mixtures, and to disguise the bitterness of quinine, with which it forms an insoluble compound. All mixtures of quinine and liquorice should be given in substance, never filtered.

Related Preparation.—EXTRACTUM GLYCYRRHIZÆ DEPURATUM (N. F.), *Purified extract of glycyrrhiza*, *Purified extract of liquorice*.—Formulary number, 158: "Extract of glycyrrhiza, in sticks; water, each, a sufficient quantity. Put a layer of well-washed rye-straw over the bottom of a keg or other suitable tall vessel. Then put a single layer of sticks of extract of glycyrrhiza, broken into coarse pieces, over it. Continue to put in alternate layers of straw and extract of glycyrrhiza until the vessel is full, or the whole of the extract has been disposed of. Fill the vessel with cold water, and allow it to remain for 3 days. Then draw off the solution which has formed, by means of a faucet, or siphon, or otherwise, refill the vessel with cold water, and proceed as before. Mix the several solutions obtained, allow any suspended matter to subside, decant the clear solution, and strain the remainder without pressure. Finally evaporate the liquid on a water-bath to the consistence of a pilular extract. *Note.*—Purified extract of glycyrrhiza should not be confounded with the official pure extract of glycyrrhiza (*Extractum Glycyrrhizæ Purum*)"—(Nat. Form.). See above.

EXTRACTUM GOSSYPHII.—EXTRACT OF GOSSYPIUM.

SYNONYM: *Extract of cotton-root bark.*

Preparation.—Exhaust the recent inner bark of the root of the cotton plant, in small pieces, with water, a sufficient quantity, proceeding in the same manner as explained for the preparation of Aqueous Extracts, on page 758. The pilular extract should be placed in small jars, and kept well covered, to prevent, as much as possible, any loss of its virtues. Unless made of the recent root it will be inert, and even then it is a question as to whether the heat of concentration does not materially affect the product.

Medical Uses and Dosage.—Extract of cotton-root bark is emmenagogue and abortifacient. It will be found useful in *amenorrhœa* and *dysmenorrhœa*, combined with belladonna and quinine. The dose is from 1 to 5 or 10 grains, 3 times a day (J. King).

EXTRACTUM GOSSYPHII RADICIS FLUIDUM (N. F.)—FLUID EXTRACT OF COTTON-ROOT BARK.

Preparation.—"Cotton-root bark, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, two hundred and fifty cubic centimeters (250 Cc.) [8 flz, 218 M]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 flz, 391 M]. Mix the glycerin with seven hundred and fifty cubic centimeters (750 Cc.) [25 flz, 173 M] of alcohol, and, having moistened the powder with five hundred cubic centimeters (500 Cc.) [16 flz, 435 M] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then alcohol, until the cotton-root bark is exhausted. Reserve the first seven hundred cubic centimeters (700 Cc.) [23 flz, 321 M] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 flz, 391 M]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Gossypium*). This preparation is a bright-red fluid. It should be prepared from the recently dried root bark. Dose, $\frac{1}{2}$ to 1 fluid drachm.

Gossypium fluid extract is typical of those red-tannin liquids that disintegrate spontaneously. The product is a brown magma and a watery serum. No

explanation has been given for this change, which occurs without warning, and which may affect only a few bottles in a batch.

EXTRACTUM GRINDELIAE FLUIDUM (U. S. P.)—FLUID EXTRACT OF GRINDELIA.

Preparation.—"Grindelia, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 oz., 120 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M̄]. Moisten the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄3, 69 M̄] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol until the grindelia is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄3, 356 M̄] of the percolate. Distill off the alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Grindelia*). This well represents the virtues of grindelia, the activity of which probably depends upon its resin and essential oil, alcohol being, therefore, the proper menstruum. It is a dark brown-green fluid, having the characteristic odor of the plant, and does not mix well with water owing to the abundance of resinous material present, which separates when so treated. This fluid extract was originated by Parke, Davis & Co., of Detroit, to whom belongs the credit of its introduction. Dose, 10 to 60 minims.

EXTRACTUM GUARANÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF GUARANA.

Preparation.—"Guarana, in No. 80 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M̄]. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄3, 173 M̄] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄3, 218 M̄] of water, and, having moistened the powder with two hundred cubic centimeters (200 Cc.) [6 fl̄3, 366 M̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the guarana is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄3, 25 M̄] of the percolate. Distill off the alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Guarana*). This is a dark reddish-brown fluid, of an astringent bitter taste. If too little alcohol be used in the menstruum, as in former processes, a heavy precipitate falls. Glycerin, in our opinion, is desirable as a part of the menstruum, both as a solvent and as a preventive of precipitation. Dose, from 20 to 60 minims.

EXTRACTUM HAMAMELIDIS FLUIDUM (U. S. P.)—FLUID EXTRACT OF HAMAMELIS.

Preparation.—"Hamamelis, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl̄3, 183 M̄]; alcohol, water, each a sufficient quantity. Mix the glycerin

with five hundred cubic centimeters (500 Cc.) [16 fl̄, 435 M] of alcohol, and eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 M] of water, and, having moistened the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 M] of the mixture, pack it firmly in a conical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then a mixture of alcohol and water, made in the proportion of five hundred cubic centimeters (500 Cc.) [16 fl̄, 435 M] of alcohol to eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 M] of water, until the hamamelis is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 M] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M].—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Hamamelis*). This fluid has a deep red-brown color, and the bitter and astringent taste of witch-hazel leaves. This fluid extract fully represents the virtues of hamamelis and may be employed to fulfil the indications for that drug, particularly where the action of an astringent is desired. It should not be confounded with *Aqua Hamamelidis*, which is often called extract of witch-hazel. Dose, from 10 to 30 minims.

EXTRACTUM HÆMATOXYLI (U. S. P.)—EXTRACT OF HÆMATOXYLON.

SYNONYMS: *Extract of logwood, Extractum ligni campechiani.*

Preparation.—“Hæmatoxylon, rasped, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; water, ten thousand cubic centimeters (10,000 Cc.) [338 fl̄, 66 M]. Macerate the hæmatoxylon with the water for 48 hours. Then boil (avoiding the use of metallic vessels) until one-half of the water has evaporated; strain the decoction while hot, and evaporate to dryness”—(U. S. P.).

Description, Medical Uses, and Dosage.—The above process should not be carried on in an iron vessel, on account of the astringent principle present. Extract of logwood should be a dry, non-hygroscopic, fragile, pulverulent mass, of a ruby-red color and a sweet taste, followed by astringency. Brande states that 20 pounds of the extract may be obtained from a hundred-weight of the rasped wood. The usual yield, however, is about 12 per cent. Old extract becomes very hard, frequently passing through the bowels undissolved when given in pills, and should, therefore, not be used in their preparation, but only in solutions. It forms a nearly clear, ruby-red solution in water. It is largely prepared where logwood is indigenous, and is much used in the arts.

Extract of logwood is astringent and tonic, and will be found useful in *diarrhœa*, *dysenteric diarrhœa*, relaxed conditions of the bowels succeeding *cholera infantum*, and in *chronic laryngitis* or *bronchitis* accompanied with considerable mucous expectoration. The dose is from 5 to 30 grains, 2 or 3 times a day. In 3 cases of *chronic diarrhœa*, with mucous, bloody, and purulent discharges of the bowels, from ulceration of the colon, Prof. A. J. Howe, M. D., succeeded in arresting the abnormal evacuations, when several approved remedies had been tried in vain, by means of a strong solution of extract of logwood. About 2 ounces of the extract were dissolved in a pint of warm water, of which, when cold, a tablespoonful was given for a dose, repeating it every 3 hours.

EXTRACTUM HUMULI FLUIDUM (N. F.)—FLUID EXTRACT OF HOPS.

Preparation.—*Formulary number, 160:* “From the strobiles of *Humulus Lupulus*, Linné (*Hops*). *Process A* (see F. 135). No. 20 powder. *Menstruum:* Alcohol, 5 volumes; water, 3 volumes”—(*Nat. Form.*).

Medical Uses and Dosage.—(See *Humulus*). Dose, 10 to 60 minims.

EXTRACTUM HYDRANGÆ FLUIDUM (N. F.)—FLUID EXTRACT OF HYDRANGÆ.

Preparation.—*Formulary number, 161:* “From the root of *Hydrangæa arborescens*, Linné (*Seven barks*). *Process A* (see F. 135). No. 60 powder. *Menstruum:* Alcohol, 3 volumes; water, 2 volumes”—(*Nat. Form.*).

Medical Uses and Dosage.—(See *Hydrangæa*). Valuable in irritable conditions of the urethra and bladder, from the presence of stone or gravel, etc., and to change the character of lithic urine. The dose is from $\frac{1}{4}$ to 1 fluid drachm.

EXTRACTUM HYDRASTIS.—EXTRACT OF HYDRASTIS.

SYNONYM: *Extract of golden seal.*

Preparation.—Mix powdered golden-seal root with enough diluted alcohol to thoroughly moisten it; in 24 hours put the whole into a percolator, and exhaust with diluted alcohol. Distill the alcohol from this filtered tincture, and evaporate the remainder to the consistence of an extract.

Medical Uses and Dosage.—This extract possesses all the tonic virtues of the root, and may be used in all cases where it is indicated. In many instances it will be preferable to the hydrochlorate of berberine, on account of the insolubility of the latter. The dose is from 2 to 5 grains, 3 times a day (J. King).

EXTRACTUM HYDRASTIS FLUIDUM (U. S. P.)—FLUID EXTRACT OF HYDRASTIS.

Preparation.—“Hydrastis, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lb. av., 3 ozs., 120 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl̄3, 183 Ml]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 Ml]. Mix the glycerin with six hundred cubic centimeters (600 Cc.) [20 fl̄3, 138 Ml] of alcohol, and three hundred cubic centimeters (300 Cc.) [10 fl̄3, 69 Ml] of water, and, having moistened the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄3, 69 Ml] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then a mixture of alcohol and water, made in the proportion of six hundred cubic centimeters (600 Cc.) [20 fl̄3, 138 Ml] of alcohol to three hundred cubic centimeters (300 Cc.) [10 fl̄3, 69 Ml] of water, until the hydrastis is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄3, 356 Ml] of the percolate. Distill off the alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 Ml]”—(*U. S. P.*).

Description, Medical Uses, and Dosage.—(See *Hydrastis*). This preparation has a dark brownish-yellow color, and the characteristic and bitter taste of golden seal. The glycerin has no value that we can discover, and might well be replaced with advantage by a like volume of alcohol. Dose, 10 to 60 minims.

EXTRACTUM HYOSCYAMI (U. S. P.)—EXTRACT OF HYOSCYAMUS.

SYNONYMS: *Extractum hyoscyami alcoholicum, Extract of henbane.*

Preparation.—“Hyoscyamus, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, two thousand cubic centimeters (2000 Cc.) [67 fl̄3, 301 Ml]; water, one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 Ml]; diluted alcohol, a sufficient quantity. Mix the alcohol and water,

and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 M.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then diluted alcohol, until three thousand cubic centimeters (3000 Cc.) [101 fl̄, 212 M.] of the tincture are obtained, or the hyoscyamus is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 M.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M.]; mix this with the reserved portion, and evaporate, at or below the before-mentioned temperature, to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Hyoscyamus*). This extract has a greenish-brown or olive color, with the heavy narcotic odor of henbane. Old extracts of hyoscyamus exhibit crystals, which are said to be those of potassium nitrate and sodium chloride. Even the official extract is not considered a first-class therapeutical agent. It contains, in a measure, the medicinal virtues of the henbane, and may be administered whenever this drug is indicated. The dose is from $\frac{1}{4}$ to 2 or 3 grains, 3 times a day. The smallest dose must first be given, and the quantity gradually increased until the desired influence is experienced.

EXTRACTUM HYOSCYAMI FLUIDUM (U. S. P.)—FLUID EXTRACT OF HYOSCYAMUS.

Preparation.—"Hyoscyamus, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 8 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]. Mix two thousand cubic centimeters (2000 Cc.) [67 fl̄, 301 M.] of alcohol with one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 M.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the hyoscyamus is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 M.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]"—(U. S. P.).

Description, Medical Uses, and Dosage.—This forms an elegant and durable preparation of hyoscyamus. In percolation the fluid should be allowed to pass very slowly, that thorough exhaustion of the leaves may take place. It has a very deep greenish-brown hue, and the narcotic odor of henbane. This extract possesses all the virtues of hyoscyamus, and may be given wherever the influence of the plant is desired. The dose is 5 minims, increased cautiously to 30 minims, or until the desired action is obtained.

EXTRACTUM IGNATIÆ AMARÆ.—EXTRACT OF IGNATIA.

SYNONYM: *Extract of St. Ignatius' bean.*

Preparation.—Take of St. Ignatius' beans, 1 pound, bruise them in an iron or brass mortar until reduced to small fragments or very coarse powder; moisten them with water in a covered vessel, and apply heat until the tissues of the pieces become soft, and can be bruised into a pulpy mass. Mix this mass with alcohol, 0.820, twice its bulk, and macerate in a close vessel and in a warm place for 24 hours, then place in a percolator, and add alcohol until 10 or 12 pints of tincture have been obtained. Distill off the alcohol, heat the residue in a water-bath until

reduced to the consistence of a soft extract. About 10 per cent of a brown extract will be thus obtained, of a peculiar heavy odor, and an intensely bitter taste.

Medical Uses and Dosage.—(See *Ignatia*). Analogous to those of *nux vomica*, but probably more efficient in *nervous diseases*, *headaches*, etc. The dose is about $\frac{1}{2}$ grain, 2 or 3 times a day. It is an active and dangerous preparation, and must be used with care (W. Procter, Jr.).

EXTRACTUM IPECACUANHÆ FLUIDUM (U. S. P.)—FLUID

EXTRACT OF IPECAC.

Preparation.—“Ipecac, in No. 80 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 m̄] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄] of water, and, having moistened the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the ipecac is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Ipecacuanha*). This is a thin and transparent, deep reddish-brown fluid, with the bitterish, subacid, nauseous flavor and taste of ipecac. In the preceding revisions of the U. S. P., this fluid extract was made by a process so different as to necessitate special mention. Then the oleoresins were precipitated by water from the evaporated percolate, which was afterward alcoholated enough to preserve it. Acetic acid was also employed. By this method a fluid extract was obtained, capable of mixing with water or syrup in all proportions, the product being clear. The present U. S. P. process produces a fluid that neither has the odor of acetic acid, nor is it capable of making a clear syrup by direct admixture with simple syrup (see formula for making syrup of ipecac). Dose, as expectorant, 1 to 5 minims; as an emetic, 15 to 30 minims.

EXTRACTUM IRIDIS (U. S. P.)—EXTRACT OF IRIS.

SYNONYM: *Extract of blue flag.*

Preparation.—“Iris, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until three thousand cubic centimeters (3000 Cc.) [101 fl̄, 212 m̄] of tincture are obtained, or the iris is exhausted. Distill off the alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence”—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a dark-brown extract possessing the odor and taste of the drug. The alcoholic extract of blue flag is a valuable cathartic and alterative. In doses of from 1 to 5 grains or more, it will be found a useful purgative in cases of *obstinate constipation*, *hepatic torpor*, *indigestion*, *amenorrhœa*, etc. As a laxative the dose should be smaller. In larger doses it will produce hydragogue results, and may be given with advantage in *chronic pulmonary affections*, *dropsy*, *worms*, etc. In doses to fall short of catharsis, it

becomes a valuable alterative, and will be found especially useful in *rheumatic diseases, scrofula, syphilis*, etc., and will frequently cause pyalism. A few grains of ginger or capsicum will prevent any harshness of action. As an alterative, the dose is from $\frac{1}{4}$ to 1 grain 3 times a day (J. King).

EXTRACTUM IRIDIS FLUIDUM (U. S. P.)—FLUID EXTRACT OF IRIS.

SYNONYM: *Fluid extract of blue flag.*

Preparation.—"Iris, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lb. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 M̄] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol until the iris is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 M̄] of the percolate. Distill off the alcohol from the remainder by means of a water-bath, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—A dark red-brown fluid. When mixed with water a copious precipitate results; even a few drops impart an opalescence to much water. This fluid extract is subject to disintegration in a similar way to that of gossypium, although the change is not as frequent. The result, when alteration occurs, is a copious brown magma, that sometimes is abundant enough to render the liquid thick like mush. This fluid extract holds the virtues of blue flag in a concentrated state, and may be used in *syphilis, dropsy, scrofula*, and all diseases in which the crude article is indicated. The dose is from a fraction of a drop to 20 drops.

EXTRACTUM JALAPÆ (U. S. P.)—EXTRACT OF JALAP.

Preparation.—"Jalap, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity. Moisten the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 M̄] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol until the jalap is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 308 M̄] of the percolate. Distill off the alcohol from the remainder by means of a water-bath, and add the residue to the reserved portion, and evaporate to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—The use of water in the preparation of this extract has been abandoned, since it was learned that it extracted none of the active constituents of the drugs. Moreover, it increased the bulk by dissolving inert matter, and rendered the extract more liable to become hygroscopic, and consequently to harden. Extract of jalap is a deep-brown, tenacious extract. It is cathartic in doses of from 10 to 20 grains, but is seldom used alone, being generally added to pills to increase their laxative or cathartic effect.

EXTRACTUM JALAPÆ FLUIDUM (N. F.)—FLUID EXTRACT OF JALAP.

Preparation.—*Formulary number, 162:* "From the tuberous root of *Ezogonium Purga*, Bentham (*Jalap*). *Process A* (see F. 135). No. 60 powder. *Menstruum:* Alcohol"—(Nat. Form.).

Like the preparations of other resinous drugs this fluid extract precipitates copiously, when mixed with water, and such mixtures must be well shaken before administration.

Medical Uses and Dosage.—(See *Jalapa*). Dose, 10 to 60 minima.

EXTRACTUM JUGLANDIS (U. S. P.)—EXTRACT OF JUGLANS.

SYNONYM: *Extract of butternut.*

Preparation.—"Juglans, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl. 3, 252 M.] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until three thousand cubic centimeters (3000 Cc.) [101 fl. 3, 212 M.] of tincture are obtained, or the juglans is exhausted. Distill off the alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—Diluted alcohol, as shown by B. F. Moise, Jr. (*Amer. Jour. Pharm.*, 1881, p. 153), is the best menstruum for butternut extract. This is of a dark or reddish-brown color, a caramel-like odor, and a bitterish, somewhat astringent taste. In preparing the extract, the bark of the root should be collected between April and July, and used while fresh. It is used chiefly as a gentle cathartic, acting upon the bowels without disposing them to subsequent constipation. The dose is from 10 to 30 grains.

EXTRACTUM JUGLANDIS FLUIDUM (N. F.)—FLUID EXTRACT OF JUGLANS.

Preparation.—Formulary number, 163: "From the inner bark of the root of *Juglans cinerea*, Linné (*Butternut*). Process A (see F. 135). No. 40 powder. Menstruum: Diluted alcohol"—(Nat. Form.).

Medical Uses and Dosage.—(See *Juglans*). Dose, 10 to 60 minima.

EXTRACTUM JUNIPERI FLUIDUM (N. F.)—FLUID EXTRACT OF JUNIPER.

Preparation.—Formulary number, 164: "From the fruit of *Juniperus communis*, Linné (*Juniper*). Process A (see F. 135). No. 10 powder. Menstruum: Diluted alcohol"—(Nat. Form.).

Medical Uses and Dosage.—(See *Juniperus*). Dose, 5 to 60 minima.

EXTRACTUM KRAMERIE (U. S. P.)—EXTRACT OF KRAMERIA.

SYNONYM: *Extract of rhatany.*

Preparation.—"Krameria, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; water, a sufficient quantity. Moisten the powder with three hundred cubic centimeters (300 Cc.) [10 fl. 3, 69 M.] of water, pack it in a conical glass percolator, and gradually pour water upon it, until the infusion passes but slightly imbued with the astringency of the krameria. Heat the liquid to the boiling point, strain, and evaporate the strained liquid, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), to dryness"—(U. S. P.).

Description, Medical Uses, and Dosage.—Good extract of rhatany is of a dark-red color, somewhat glossy, non-hygroscopic, faintly odorous, powerfully astringent, and almost wholly dissolved by water. Its evaporation should be performed quickly (or else in vacuo), as the atmosphere speedily oxidizes its active

principles, impairing them, and rendering them more or less insoluble. The bark of the root furnishes the greatest amount of extract, and that prepared with water is superior to that made with alcohol. For some purposes a soft extract is prepared by stopping the evaporation at the proper time. Much of the extract of rhatany found in commerce is of an inferior quality. It does not keep well, becoming brittle and hard by age, even in close containers. Extract of rhatany may be used whenever an astringent is required; in some cases it will be found preferable to any other agent of this class. The soft extract may be advantageously used as a local application to *ulcers, hemorrhoids, and fissures of the anus*. The dose is from 5 to 20 grains, 3 or 4 times a day.

EXTRACTUM KRAMERIÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF KRAMERIA.

SYNONYM: *Fluid extract of rhatany.*

Preparation.—"Krameria, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 m̄]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix the glycerin with nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of diluted alcohol, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards diluted alcohol, until the krameria is exhausted. Reserve the first seven hundred cubic centimeters (700 Cc.) [23 fl̄, 321 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Krameria*). A deep brown-red, decidedly astringent fluid. It may be used where the amount of alcohol contained in the tincture is objectionable, and besides, possesses greater astringency than the latter preparation. It is prone to disintegrate, behaving like other red-tannate fluids (see *Fluid Extract of Gossypium*). Dose, 10 to 60 minims.

EXTRACTUM LACTUCARI FLUIDUM (N. F.)—FLUID EXTRACT OF LACTUCARIUM.

Preparation.—*Formulary number, 166:* "Lactucarium, in coarse powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; ether, one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl̄, 109 m̄]; alcohol, water, each, a sufficient quantity. Add the lactucarium to the ether contained in a tared flask having the capacity of six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 m̄], and let it macerate for 24 hours; then add three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of water, and shake the mixture well. Fit a bent glass tube into the neck of the flask, and, having immersed the flask in hot water, recover the ether by distillation. When all the ether has distilled over, remove the tube, and, after thoroughly shaking the contents of the flask, continue the heat for $\frac{1}{2}$ hour. Let the mixture cool, add one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.] of alcohol, and enough water to make the whole mixture weigh five hundred grammes (500 Gm.) [1 lb. av., 1 oz., 279 grs.]; after maceration for 24 hours, with occasional agitation, express and filter the liquid. Return the dregs to the flask and macerate them with two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.] of a mixture of alcohol and water made in the proportion of 1 part of alcohol to 3 parts of water; repeat the maceration 2 or 3 times, successively, with fresh portions of the mixture, until the dregs are tasteless, or nearly so. Mix and filter the liquids thus obtained, and concentrate them, by means of a water-bath (the first expressed

liquid by itself), until the combined weight of the liquids is sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]; mix the liquids, add forty grammes (40 Gm.) [1 oz., av., 180 grs.] of alcohol, and let the mixture cool in the evaporating vessel, stirring the mixture frequently, and during the intervals keeping the vessel well covered. When cool, add enough alcohol to make the mixture weigh one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; transfer the liquid to a flask, and add enough water to make the mixture measure one hundred cubic centimeters (100 Cc.) [3 fl̄3, 183 M], using the water so required to rinse the evaporating vessel. Shake the mixture occasionally, during several hours (and frequently, if a portion of the precipitate is found to be tenacious), and, when a uniform mixture results, set it aside for 24 hours, so that any precipitate formed may subside. Decant the clear liquid, transfer the precipitate to a filter, and, after thoroughly draining it into the decanted liquid, wash it with a mixture of alcohol and water made in the proportion of 3 parts of alcohol to 4 parts of water, until the washings pass tasteless. Concentrate the washings, by evaporation, to a syrupy consistence, mix with the decanted liquid, and add enough of the last-named mixture of alcohol and water to make the whole measure one hundred cubic centimeters (100 Cc.) [3 fl̄3, 183 M]. Lastly, after 24 hours, having meanwhile shaken the fluid extract occasionally, filter it through paper" (*Nat. Form.*).

Medical Uses and Dosage.—(See *Lactucarium*). Dose, 1 to 5 grains.

Related Preparation.—EXTRACTUM LACTUCÆ (*Br.*), *Extract of lettuce*, *Extractum lactuce virosæ*, *Thridacium*. The British official preparation is merely the inspissated juice of *Lactuca virosa*. Feebly hypnotic. Dose, 5 grains.

EXTRACTUM LAPPÆ.—EXTRACT OF LAPPA.

SYNONYM: *Extract of burdock.*

Preparation.—Exhaust burdock root, coarsely powdered, or in pieces, with water, a sufficient quantity, proceeding in the same manner as explained for the preparation of Aqueous Extracts, on page 758.

Medical Uses and Dosage.—Extract of burdock is principally used as an alterative, in *scrofula*, *syphilis*, *cutaneous affections*, etc. Dose, from 5 to 20 grains, 3 times a day.

EXTRACTUM LAPPÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF LAPPA.

SYNONYM: *Fluid extract of burdock.*

Preparation.—"Lappa, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M]. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄3, 252 M] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the lappa is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄3, 25 M] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M]" (*U. S. P.*).

Description, Medical Uses, and Dosage.—(See *Lappa*). A dark brown-red fluid. Dose, $\frac{1}{4}$ to 2 fluid drachms.

EXTRACTUM LEONURI.—EXTRACT OF LEONURUS.

SYNONYM: *Extract of motherwort.*

Preparation.—Exhaust the recently dried herb of *Leonurus cardiaca*, in coarse powder, with alcohol, water, each, a sufficient quantity, proceeding in the same manner as explained for the preparation of Alcoholic Extracts, on page 758 (*J. King*).

Medical Uses and Dosage.—Extract of motherwort is emmenagogue, nervine, and antispasmodic, and may be used with advantage in all forms of disease in which the cold infusion of the herb is recommended. The dose is from 3 to 6 grains, every 2 or 4 hours. It may be advantageously combined with the extracts of *asclepias*, black cohosh, nerve root, cramp bark, scullcap, etc.

EXTRACTUM LEPTANDRÆ (U. S. P.)—EXTRACT OF LEPTANDRA.

Preparation.—"Leptandra, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl. 3, 173 M.] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl. 3, 218 M.] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl. 3, 252 M.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the leptandra is exhausted. Distill off the alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence"—(U. S. P.).

Description and History.—This is a blackish-brown extract, partially dissolving in water, a deep-brown, bitter solution resulting. (For remarks concerning *Leptandrin* and *Extract of Leptandra*, see *Leptandra*).

Medical Uses and Dosage.—Extract of leptandra is a powerful cholagogue, with but slight laxative influence; except given in very large doses its cathartic powers are but very feeble. It is one of the most efficient and important agents among those of American origin, being the only known medicine that efficiently stimulates and corrects the hepatic secretions and functional derangements of the liver, without debilitating the system by copious alvine evacuations. It may be safely and efficiently employed in the treatment of *diarrhœa*, *cholera infantum*, some forms of *dyspepsia*, *typhoid fever*, and all diseases connected with biliary derangements. Combined with resin of podophyllum it is a prompt and effectual remedy in *epidemic dysentery*, often effecting a permanent cure in from 12 to 18 hours; in dysentery, with irritable bowels, it may be used alone with advantage, or combined with camphor, as in such cases its union with resin of podophyllum is contraindicated. In *intermittents* it renders the action of quinine, when united with it, more certain, and prevents the liability to a return of the disease, at least for the season, and is likewise highly beneficial in *infantile remittent fever*, and in periodic diseases generally, of an obstinate character, in which quinine alone seems to produce little or no result. It may also be used in many other combinations with much advantage, as with hydrochlorate of berberine, or dried ox-gall, in some *dyspeptic affections*, *jaundice*, *piles*, etc., or with oleoresin of blue flag, extract of wild indigo, extract of poke, extract of turkey corn, resin of blue cohosh, and other active principles, in various forms of disease. Dose of extract of leptandra, from $\frac{1}{2}$ to 5, 6, or 7 grains, every 3 or 4 hours, according to the action or effect desired. Some practitioners neglect the use of this agent, because it does not act so powerfully as resin of podophyllum, and hence lose the influence of a very important remedy in functional derangements of the liver, and other organs essential to digestion. The above remarks refer to both the ordinary extract and the dried extract, heretofore known as "*Leptandrin*" (King). In relation to the dried extract (*leptandrin*) Prof. Hill observes, and which observations will apply with equal force to the ordinary extract:

"This is not, strictly speaking, a cathartic. It is aperient, alterative, and tonic. Its effects on the liver are peculiar. In cases of children afflicted with *summer complaint*, where there is evidently a lack of the proper biliary secretion, but where, owing to the already irritated condition of the bowels, the ordinary medicines for arousing the liver are inadmissible, this article seems to be the very thing needed. While it acts freely upon the liver, instead of purging, it seems

only to change the discharges from the light and watery or slimy condition, to a darker and apparently bilious state, rendering them more and more consistent, until they become perfectly natural, without having been arrested entirely, or at any time aggravated. It at the same time seems to act as a tonic, restoring the tone of the stomach and increasing the strength and activity of digestion. It is a most valuable remedy in *dyspepsia*.

"The dose is from $\frac{1}{4}$ to 1 grain every 1 or 2 hours in acute cases, and from 1 to 2 grains, 3 times a day, in chronic cases. It is valuable to combine with resin of podophyllum as a remedy in *dyspepsia* and *chronic hepatitis*.

"In the *epidemic dysentery*, which has prevailed for the past two seasons in many parts of our country, this article has been of great service. It was usually given with the best success after evacuating the bowels freely, with a combination of resin of podophyllum and dried extract of leptandra or rhubarb. (I have omitted the old incorrect names of *leptandrin* and *podophyllin*, in the original, and substituted the correct ones [King]). For this purpose, give from $\frac{1}{4}$ to 1 grain every hour, gradually lengthening the intervals as the discharges become darker. Though it may not be applicable in all cases of dysentery, it is doubtless one of the most useful articles in this dangerous disease."

In *cholera infantum*, a disease which sometimes sets at defiance all the skill of the physician, Prof. King met with excellent success with the following combination: Take of dried extract of leptandra, 6 grains; quinine, 3 grains; camphor, $1\frac{1}{2}$ grains; ipecacuanha, $\frac{1}{2}$ grain. Mix and divide into 12 powders of which 1 may be given every 2 or 3 hours, and its use continued thus for several days. Its action at first is to increase the alvine passages and apparently augment the disease, but in a few days the character of the evacuations changes, they become more and more normal, as well as more regular in their appearance; after which, 1 or 2 powders per day for a week, will render the cure permanent. This powder, in large doses for adults, will be found very efficient in painful *diarrhœa* and *dysentery*, as well as in severe pains depending upon *intestinal irritation*. The following has also been of advantage in *cholera infantum*: Triturate together, charcoal 1 drachm, with dried extract of leptandra 3 grains, and divide into 12 powders, of which 1 powder is to be given every 2 or 3 hours until the evacuations become more natural, after which, give 1 or 2 powders a day for a few days.

Extract of leptandra will be found to act with more certainty when it is given in a soluble form, as in tincture, weak solution of potassa, etc. Like hydrochlorate of berberine, and other concentrated preparations which are insoluble in water, it frequently passes through the alimentary canal unchanged, when given in the form of powder.

EXTRACTUM LEPTANDRÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF LEPTANDRA.

Preparation.—"Leptandra, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 m̄] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before until the leptandra is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Leptandra*). This is a dark, reddish-brown, very bitter fluid. It is laxative, cholagogue, and tonic, and may

be advantageously substituted for the root in all cases. The dose is from 10 to 60 minims, 1, 2, or 3 times a day. As a laxative, it is preferable to the extract, when dried.

EXTRACTUM LOBELIÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF LOBELIA.

Preparation.—"Lobelia, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the lobelia is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 m̄] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a dark greenish-brown fluid exhibiting the acrid and nauseating properties of lobelia. It may be used wherever lobelia is indicated. The dose is from 5 minims to 1 fluid drachm, according to the effect required, and which are equivalent to 5 grains to 1 drachm of the powder.

EXTRACTUM LOBELIÆ FLUIDUM COMPOSITUM.—COMPOUND FLUID EXTRACT OF LOBELIA.

Preparation.—Take of recently dried bloodroot, skunk-cabbage root, and lobelia seed and leaves, each, coarsely powdered, 4 troy ounces; alcohol, diluted alcohol, each, a sufficient quantity. Moisten the powders mixed together, with sufficient alcohol, and let them stand for 24 hours; then transfer the mixture to a percolator, and gradually add alcohol, returning a little of the first that passes, until it runs clear. Reserve, by itself, of the first or strongest percolate, 12 fluid ounces; then pour diluted alcohol on the residuum in the percolator, until the liquid that comes through has very little of the color or taste of the medicine; evaporate this latter solution to 4 fluid ounces by a heat considerably below the boiling point, and while warm mix in the reserved tincture, and make 1 pint of fluid extract.

Medical Uses and Dosage.—This fluid extract is emetic, expectorant, and antispasmodic, and may be used as a substitute for the acetated tincture of bloodroot; A fluid drachm of the extract is equivalent to about 1 drachm of the powder; the dose is from 10 to 60 minims, according to the desired effect (E. S. Wayne).

EXTRACTUM LUPULINI.—EXTRACT OF LUPULIN.

Preparation.—Take of commercial lupulin, 4 ounces; alcohol, 8 fluid ounces. Place the lupulin loosely in a percolator, cover with alcohol, and allow it to stand an hour. Then gradually add alcohol until 2 pints of filtered liquor are obtained, or the drug is practically exhausted. Distill or evaporate off the alcohol, reducing the residue to the consistence of a soft extract. The above extract contains the medicinal principles of the lupulin unimpaired, is of uniform strength, and is in a form convenient for pills. Commercial lupulin yields about 40 grains of extract to 1 drachm of the grains.

Medical Uses and Dosage.—(See *Lupulinum*). This extract possesses the active properties of the hops in an eminent degree, and may be used in all cases where lupulin is admissible. The dose is from 2 to 10 grains, 3 times a day.

EXTRACTUM LUPULINI FLUIDUM (U. S. P.)—FLUID EXTRACT OF LUPULIN.

Preparation.—"Lupulin, one thousand grammes (1000 Gm.) [2 lbs. av., 3 oz., 120 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Moisten the lupulin with two hundred cubic centimeters (200 Cc.) [6 fl̄, 366 M] of alcohol, and pack it firmly in a cylindrical percolator. Then add enough alcohol to saturate the lupulin and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the lupulin is exhausted. Reserve the first seven hundred cubic centimeters (700 Cc.) [23 fl̄, 321 M] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Lupulinum*). A dark reddish-brown fluid, possessing the taste and odor of hops. Owing to its resinous nature, it can not be mixed with aqueous preparations without the presence of some emulsifying medium. Robbins suggests that lupulin be packed unmoistened to avoid the formation of a mass which is percolated with difficulty. This fluid extract may be used wherever lupulin is indicated; 1 fluid drachm is equivalent to 1 drachm of lupulin, so the dose can be readily proportioned. It may be advantageously combined, at times, with fluid extract of scutellaria, wild cherry, or valerian, etc.

EXTRACTUM MALTI.—EXTRACT OF MALT.

Preparation.—Take of fresh barley malt any desired amount, water, a sufficient quantity; heat the water to a temperature of from 37.7° to 65.5° C. (100° to 150° F.), and moisten the malt with a portion of it. Pack the moistened malt loosely, in a cylindrical percolator of suitable size, and then add more of the water, at the same temperature, until the percolate appears at the exit. Now close the exit with a cork, and allow the whole to macerate, in a warm place, for from 3 to 6 hours. At the expiration of this time, open the exit, and allow the percolation to proceed, adding fresh supplies of heated water, until the percolate has yielded, in weight, an amount equal to twice that of the malt employed. Lastly, evaporate at a temperature ranging from 80° to 94° C. (about 180° to 200° F.), with constant stirring to the consistence of a soft extract. The only full-strength, diastase-bearing extract of malt is made by means of a vacuum apparatus.

Description.—In the preceding process, if the operation of the percolation be neglected, or if the percolate be allowed to stand a short time previous to evaporation, fermentation will speedily ensue, and the resulting extract will have an acid, disagreeable taste. If the temperature be permitted to rise above the boiling point of water after the extract has become somewhat concentrated, a burnt flavor will be imparted to it. The diastase is destroyed at a less temperature. Extract of malt is a translucent, reddish-brown, adhesive substance, of an agreeable, somewhat sweetish, but not positively saccharine taste. An infusion of pure malt has the correct flavor peculiar to fresh malt, and evaporation does not appreciably increase its sweetness; therefore, should any extract of malt have a decidedly syrup-like taste, it may be suspected that some sweetish substance has been added to it, either to overcome the effects of fermentation or to increase the consistence of the extract without the proper evaporation. Glucose appears to be peculiarly adapted for these purposes, and, if the fermentation be not excessive, the addition of this substance will accomplish both objects. This is, probably the only adulterant that will be found.

Medical Uses and Dosage.—This article was introduced into this country from Germany, where it had been used for some time as a tonic and nutrient in *anorexia*, *chronic bronchitis*, *phthisis*, *asthma*, *dyspepsia*, convalescence from exhausting maladies, and in all diseases accompanied by general debility, and impairment of the vital powers; its beneficial effects in these diseases appear to be due

to the diastase and the nutritive principles entering into its composition. It forms an excellent substitute for malt liquors in those cases where even a gentle stimulant is contraindicated. At the present time our manufacturers have thrown many malt preparations upon the market into which iron, cod-liver oil, pepsin, quinine, iodides, etc., enter, and apparently without regard to the compatibilities or incompatibilities of the articles thus thrown together; and it is doubtful whether such mixtures exert as beneficial results in the diseases for which they are recommended, as would ensue were the drugs taken separately and alternately, with the malt extract. The dose of extract of malt is from 1 to 4 fluid drachms in milk, or in soup, repeating it 3 times a day.

Related Preparations.—**MALTINE.** This is a specialty of the Maltine Manufacturing Company of New York City. It is recommended as a palatable, stable and uniform extract of malt of high diastatic power, differing from other malt extracts in containing in addition to the virtues of malted barley the nutritive principles of wheat and oats.

Maltine Plain, is used extensively as a digestant, nutrient, adjunct infant food, galactagogue, and vehicle. The following maltine preparations are also in common use: (1) *Maltine with Cod-liver Oil*; (2) *Maltine with Pepsin and Pancreatin*; (3) *Maltine with Hypophosphites*—lime, soda, iron; (4) *Malto-Yerbine*, containing active principles of *Yerba Santa*; (5) *Maltine Ferrated*—iron pyrophosphate; (6) *Maltine with Phosphate of Iron, Quinia and Strychnia*; (7) *Maltine with Peptones*—beef; (8) *Maltine with Wine of Pepsin*; (9) *Maltine with Coca Wine*; (10) *Maltine with Cascara Sagrada*.

EXTRACTUM MALTI COMPOSITUM.—COMPOUND

EXTRACT OF MALT.

SYNONYM: *Extract of malt and hops.*

Preparation.—To 1 part of fresh hops, ground, add 9 parts of malt (1 in 10), and make an extract in the same manner as directed for the simple extract of malt. The odor of the hops is not observed in this preparation owing to the subsequent evaporation, but the bitter taste remains quite distinct. There are many mixtures at present upon the market that contain a greater or lesser amount of extract of malt, but it is not in accordance with our purpose to describe them.

Medical Uses and Dosage.—This preparation differs from the preceding only in the presence of hops, which may impart to it a slight hypnotic influence. It may be used in the same cases, and in the same doses, as named for the extract of malt.

EXTRACTUM MALTI FLUIDUM (N. F.)—FLUID

EXTRACT OF MALT.

Preparation.—*Formulary number, 168:* "Malt, one thousand grammes (1000 Gm.) [2 lbs. av., 8 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity. Reduce the malt to a coarse powder, not finer than No. 20. Moisten it with five hundred cubic centimeters (500 Cc.) [16 fl $\frac{3}{4}$, 435 M.] of a mixture of 1 volume of alcohol and 3 volumes of water, and set it aside well covered, until it has ceased to swell. Then mix it with as much of the menstruum as it will take up without dripping, pack it uniformly, but without pressure, in a percolator, and add enough of the before-mentioned menstruum to cover it. When the liquid begins to drop from the orifice, close the latter, and allow the contents to macerate during 24 hours, adding from time to time more menstruum, if necessary, to keep the malt just covered. Then remove the cork and allow the percolation to proceed until the percolate weighs seven hundred and fifty grammes (750 Gm.) [1 lb. av., 10 ozs., 199 grs.]. Set this aside, well corked, until any suspended matters have been deposited. Then decant the clear liquid and preserve it for use. *Note.*—The product thus obtained may be regarded as being practically equivalent to the drug in the proportion of minim for grain, the apparent excess of dissolved matters present in the first portions of the percolate being offset by the soluble matters still remaining in the drug, when the percolation is interrupted"—(*Nat. Form.*).

Description, Medical Uses, and Dosage.—Fluid extract of malt possesses the taste of fresh malt, but is not sweet, and as prepared by the preceding process, will not ferment. It represents in each fluid ounce the soluble principles of 1 $\frac{1}{2}$

troy ounces of malt. It is a thin, yellow or brownish-yellow liquid. (For uses, see *Maltum*.) The dose varies according to the individual and effects desired (see *Extractum Malti*).

EXTRACTUM MANGIFERÆ FLUIDUM.—FLUID EXTRACT OF MANGIFERA.

Preparation.—Take of the bark of *Mangifera indica*, in moderately fine powder, 20 troy ounces; of a menstruum of glycerin, 6 fluid ounces; water, 10 fluid ounces (by measure), a sufficient quantity. Add the powder to 64 fluid ounces of the menstruum, in a suitable vessel, and let it macerate for 24 hours, with occasional stirring. Then place it in a muslin strainer, and express; filter the expressed liquid through paper. Return the material within the muslin strainer to the vessel, add 32 fluid ounces of water, and allow this to macerate for 24 hours, when it must be expressed and filtered, as at first. Mix the two filtrates, and, by means of a water-bath, evaporate until the fluid is reduced to 13 fluid ounces, when 3 fluid ounces of alcohol is to be added. *Mangifera indica* is one of the most difficult substances we have ever attempted to extract by percolation, providing the menstruum is adapted to take up the tannates, with which the bark abounds. In such a case, the menstruum will seldom penetrate beyond an inch or so into the powder, even if it is very coarse; therefore, we prefer and employ maceration.

Description, Medical Uses, and Dosage.—Fluid extract of mangifera is of a dark, ruby-red color when in thin layer, of a peculiar odor, and a sweetish (glycerin), and very astringent taste. This preparation was introduced to the medical profession by Dr. M. F. Linquist, of New Haven, Conn. (For uses, see *Mangifera*.) Dose, 15 to 60 minims.

EXTRACTUM MATICO FLUIDUM (U. S. P.)—FLUID EXTRACT OF MATICO.

Preparation.—“Matico, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 Ml]. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 Ml] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 Ml] of water, and, having moistened the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 Ml] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the matico is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 Ml] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 Ml]”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Matico*). This preparation well represents the virtues of matico, although in our opinion a better representative results when alcohol alone is employed, instead of a mixture of alcohol and water. It is of a greenish-black color as made by the official process, of a green color when made with alcohol only. Dose, 20 minims to 2 fluid drachms.

EXTRACTUM MENISPERMI FLUIDUM (U. S. P.)—FLUID EXTRACT OF MENISPERMUM.

SYNONYMS: *Fluid extract of yellow parilla, Fluid extract of Canadian moonseed.*

Preparation.—“Menispermum, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make

one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 m̄] of alcohol with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the menispermum is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄].”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Menispermum*). This is an unpleasantly bitter, dark, reddish-brown liquid. Dose, 15 to 60 minims.

EXTRACTUM MEZEREI FLUIDUM (U. S. P.)—FLUID EXTRACT OF MEZEREUM.

Preparation.—“Mezereum, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 8 ozs., 120 gra.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the mezereum is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate. Distill off the alcohol from the remainder by means of a water-bath, and evaporate the residue, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄].”—(U. S. P.).

Description and Medical Uses.—This is an acrid green liquid, used chiefly to maintain a discharge from blistered parts. It is used in the preparation of *Linimentum Sinapis Compositum*. The *British Pharmacopœia* directs an ethereal extract of mezereum used in the compound liniment of mustard (see below). It is scarcely used at all in America.

Related Preparations.—EXTRACTUM MEZEREI ÆTHEREUM (Br.), *Ethereal extract of mezereum*.—This is prepared essentially as follows: Prepare a strong alcoholic tincture of mezereum bark, and distill until a mass of the consistence of a soft extract is left behind; agitate with ether, decant the ethereal solution, distill off the ether, and convert the residue into a soft extract of the consistence of honey.

EXTRACTUM MEZEREI FLUIDUM (N. F., U. S. P., 1880), *Fluid extract of mezereum*.—Formulary number, 170: “From the bark of *Daphne Mezereum*, Linné, and of other species of *Daphne* (*Mezereum*). Process A (see F. 135). No. 30 powder. Menstruum: Alcohol.”—(Nat. Form.).

EXTRACTUM MITCHELLÆ.—EXTRACT OF MITCHELLA.

SYNONYM: *Extract of partridge berry.*

Preparation.—Exhaust the recently dried herb, *Mitchella repens*, in coarse powder, with alcohol, water, each, a sufficient quantity, proceeding in the same manner as explained for the preparation of Alcoholic Extracts, on page 758.

Medical Uses and Dosage.—(See *Mitchella*). This extract is an invaluable preparation, and possesses the active medicinal virtues of the plant. It is employed more especially on account of its tonic influence upon the uterus; and in diseases of this organ it may be usefully combined with extracts or resins of black cohosh, or caulophyllum, or extract of aletris, oleoresin of senecio, etc. The dose is from 1 to 10 grains, 3 times a day (J. King).

EXTRACTUM MYRICÆ.—EXTRACT OF MYRICA.

SYNONYMS: *Extract of bayberry bark, Myricin.*

Preparation.—Make a saturated tincture of bayberry bark, filter, distill off a portion of the alcohol, and evaporate the remainder by means of a water-bath, until the mass is of an extractive consistence. The profession is indebted to the late Dr. F. D. Hill, of this city, for first preparing and introducing this article. The term *myricin*, sometimes affixed to a dried extract of bayberry, is thus disposed of by Dr. King: "It is much to be regretted that so many of our active medicinal preparations have received names which justly belong to pure chemical principles, notwithstanding such names were given from no improper motives. It is absolutely necessary that we drop these misnomers for others more in accordance with the characters of the preparations, and the sooner this is done, the sooner will we be relieved of the charge of empiricism in these matters."

Medical Uses and Dosage.—This extract is a stimulant and astringent, and will be found a very advantageous remedy in *chronic diarrhœa* and *dysentery*, in dysentery with typhoid symptoms, and in *colliquative diarrhœa of phthisis*; in *scarlatina* it may be given with advantage, while a decoction of the bark is employed as a gargle; it will likewise be found a useful remedy for *aphthous affections*, when given internally, and applied locally. It forms an efficient application to *tender, spongy, bleeding gums*, and an excellent snuff for *polypus*, also for *headache* and *catarrhal affections*. It is likewise beneficial in *jaundice*, and in combination with extracts of *leptandra* and *apocynum*, I have successfully treated several cases of this affection. In some instances of *cholera*, it will be serviceable, given in combination with extract of *geranium*. Combined with extract of *leptandra*, resin of *podophyllum*, or some other cathartic, it may be employed with benefit in the latter stages of *typhoid fever*. Dose, from 2 to 10 grains of the powder, which may be repeated as often as required (King).

EXTRACTUM NUCIS VOMICÆ (U. S. P.)—EXTRACT OF NUX VOMICA.

Preparation.—"Nux vomica, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; acetic acid, fifty cubic centimeters (50 Cc.) [1 fl̄, 332 M]; alcohol, water, ether, sugar of milk, recently dried and in fine powder, each, a sufficient quantity. Mix alcohol and water in the proportion of seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 M] of alcohol to two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 M] of water. Mix the powder with one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M] of the mixture, to which the acetic acid had previously been added, and let it macerate, in a well-covered vessel, in a warm place, during 48 hours. Then pack it tightly in a cylindrical glass percolator; gradually pour menstruum upon it, and continue the percolation until the nux vomica is practically exhausted. Distill off the alcohol by means of a water-bath, transfer the remainder to a tared capsule, and evaporate it until it weighs about one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.]. Transfer it to a bottle of the capacity of about five hundred cubic centimeters (500 Cc.) [16 fl̄, 435 M], and wash the capsule with about fifty cubic centimeters (50 Cc.) [1 fl̄, 332 M] of warm water, adding the washings to the bottle and mixing the contents thoroughly. When the liquid extract is cold, add to it $\frac{1}{4}$ of its volume of ether, stopper the bottle, and bring the extract and ether into intimate contact by gently agitating and frequently inverting the bottle, avoiding violent shaking so as to prevent the formation of an emulsion. Pour off the ethereal layer as closely as possible, and repeat this treatment with ether several times, until a few drops of the ethereal layer no longer impart a permanent, greasy stain to filtering paper. Then transfer the contents of the bottle back to the tared capsule, using a sufficient quantity of warm water for washing. Recover the ether from the united ethereal washings, add to the oily residue about fifteen cubic centimeters (15 Cc.) [243 M] of boiling water, and then acetic acid, in drops, until the mixture has a permanent acid reaction. Then filter it

through a moistened filter, and wash the filter with a little water. Add the filtrate to the extract in the capsule, evaporate until the residue weighs about two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.], and allow it to become cold. Then determine its weight exactly, remove four grammes (4 Gm.) [62 grs.] of the mass, and assay this by the process given below, using the amounts of liquids there directed for two grammes (2 Gm.) [31 grs.] of dry extract. In another portion of five grammes (5 Gm.) [77 grs.] determine the amount of water by drying it, in a flat-bottomed capsule, at 100° C. (212° F.), until it ceases to lose weight. From the results thus obtained ascertain, by calculation, the amount of total alkaloids and of water contained in the remainder of the mass, add to this enough well-dried sugar of milk to bring the quantity of alkaloids in the final dry extract to 15 per cent, then evaporate the mass to complete dryness, reduce it to powder, and transfer it to small, well-stoppered bottles"—(U. S. P.).

ASSAY (U. S. P.)—"Extract of *nux vomica*, when assayed by the following process, should be found to contain 15 per cent of total alkaloids.

Assay of Extract of *Nux Vomica*.—"Extract of *nux vomica*, dried at 100° C. (212° F.), two grammes (2 Gm.), alcohol, ammonia water, water, chloroform, decinormal sulphuric acid (V.S.), centinormal potassium hydrate V.S., each, a sufficient quantity. Put 2 Gm. of the dried extract of *nux vomica* into a glass separator, add to it 20 Cc. of a previously prepared mixture of 2 volumes of alcohol, 1 volume of ammonia water (specific gravity 0.960), and 1 volume of water, and shake the well-stoppered separator until the extract is dissolved. Then add 20 Cc. of chloroform and agitate during 5 minutes. Allow the chloroform to separate, remove it as far as possible, pour into the separator a few cubic centimeters of chloroform, and, without shaking, draw this off through the stop-cock to wash the outlet tube. Repeat the extraction with 2 further portions of chloroform of 15 Cc. each, and wash the outlet tube each time as just directed. Collect all the chloroformic solutions in a wide beaker, expose the latter to a gentle heat, on a water-bath, until the chloroform and ammonia are completely dissipated, add to the residue 10 Cc. of decinormal sulphuric acid, measured with great care from a burette, stir gently, and then add 20 Cc. of hot water. When solution has taken place, add 2 Cc. of brazil wood T.S., and then carefully run in centinormal potassium hydrate V.S., until a permanent pinkish color is produced by the action of a slight excess of alkali upon the brazil wood indicator. Divide the number of cubic centimeters of centinormal potassium V.S. used by 10, subtract the number found from 10 (the 10 Cc. of decinormal acid used), multiply the remainder by 0.0364 and that product by 50 (or, multiply at once by 1.82), which will give the percentage of total alkaloids in the extract of *nux vomica*, it being assumed that strychnine and brucine are present in equal proportion, and the above factor being found by taking the mean of their respective molecular weights rounded off to whole numbers $[(334+394) \div 2 = 364]$ "—(U. S. P.).

A study of the foregoing formula for making the extract, shows that the use of ether is simply that of a fat remover. In our opinion, gasoline, or even benzine is its equal and is cheaper.

Extract of *nux vomica*, as now made by the official process, has a light color, owing to the presence of much milk sugar.

Description, Medical Uses, and Dosage.—(See *Nux Vomica*). This is an intensely bitter, yellow-brown extract, of a somewhat variable percentage of strychnine, but usually about 6 per cent. Of total alkaloids the official demand is 15 per cent. It is used chiefly in pills. This extract contains the powerful properties of *nux vomica*, but necessarily varies in strength, as above stated, on account of the want of a uniform quantity of strychnine in the seeds. It may be employed in cases where the action of this agent is required. It is very useful in cases of *obstinate constipation*, and may be employed in the following combination: Take extract of butternut, 2 grains; resin of podophyllum, $\frac{1}{4}$ grain; and extract of *nux vomica*, $\frac{1}{2}$ of a grain; mix thoroughly together and form a pill, which is a dose, and may be repeated 2 or 3 times daily, or until the desired effect is produced. The dose of the above extract of *nux vomica* is from $\frac{1}{4}$ to 2 grains, repeated 2 or 3 times a day, and carefully watching its effects. The small dose of the drug permits of a lower alkaloidal standard, and the interest of manufacturers should be considered whenever possible.

EXTRACTUM NUCIS VOMICÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF NUX VOMICA.

Preparation.—"Nux vomica, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; acetic acid, fifty cubic centimeters [1 fl. oz., 332 m]; alcohol, water, each, a sufficient quantity. Mix alcohol and water in the proportion of seven hundred and fifty cubic centimeters (750 Cc.) [173 m] of alcohol and two hundred and fifty cubic centimeters (250 Cc.) [218 m] of water. Moisten the powder with one thousand cubic centimeters (1000 Cc.) [33 fl. oz., 391 m] of the mixture, to which the acetic acid had previously been added, and let it digest, in a well-covered vessel, in a warm place, during 48 hours. Then pack it in a cylindrical glass percolator, and gradually pour menstruum through it, until the nux vomica is practically exhausted. Distill off the alcohol and water of a water-bath, transfer the remainder to a tared capsule, evaporate until it weighs about two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.], and allow it to become cold. Then determine the weight exactly, remove four grammes (4 Gm.) [62 grs.] of the mass, and assay this by the process given under extract of nux vomica (see *Extractum Nucis Vomicæ*), using the amounts of liquids there directed for two grammes (2 Gm.) [31 grs.] of dry extract. From the results thus obtained, ascertain, by calculation, the amount of total alkaloids in the remainder of the mass, and then add to the latter, first, three hundred cubic centimeters (300 Cc.) [10 fl. oz., 69 m] of alcohol, and afterward a sufficient quantity of a mixture of equal volumes of alcohol and 1 volume of water, so that each one hundred cubic centimeters (100 Cc.) [3 fl. oz., 183 m] of the finished fluid extract shall contain five-tenths grammes (1.5 Gm.) [23 grs.] of total alkaloids"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Nux Vomica*). This fluid extract is about one-tenth as strong as the extract of nux vomica. A fluid extract of nux vomica with this one may be made by dissolving the proper amount of the solid extract in an hydro-alcoholic menstruum, one-fourth part of which is water. Dose: 5 minims.

EXTRACTUM OPII (U. S. P.)—EXTRACT OF OPIUM

Preparation.—"Powdered opium, one hundred grammes (100 Gm.) [231 grs.]; sugar of milk, recently dried and in fine powder, water, each, a sufficient quantity. Triturate the powdered opium in a mortar thoroughly with one thousand cubic centimeters (1000 Cc.) [33 fl. oz., 391 m] of water, stirring and trituration occasionally, in the course of 12 hours, then filter through a fast-flowing, double filter, and wash the filter and residue with water, until the filtrate is nearly colorless. Concentrate the filtrate and washings in a tared capsule on a water-bath, until the residue weighs about two hundred grammes (200 Gm.) [7 ozs. av., 24 grs.], and allow it to become cold. Then determine the weight exactly, and transfer twelve grammes (12 Gm.) [185 grs.] of it to an Erlenmeyer flask of capacity of about one hundred cubic centimeters (100 Cc.) [3 fl. oz., 183 m]. Determine in this portion the amount of morphine by the process of assay given under opium, using the quantities of liquids there directed for four grammes (4 Gm.) [62 grs.] of the dry extract. In another portion of five grammes (5 Gm.) [77 grs.] determine the amount of water by drying it in a flat-bottomed capsule, at 100° C. until it ceases to lose weight. From the results thus obtained ascertain, by calculation, the amount of morphine and of water contained in the remainder of the mass, add to this enough well-dried sugar of milk to bring the quantity of morphine in the final dry extract to 18 per cent, then evaporate the whole to dryness, reduce it to powder, and transfer it to small, well-stoppered vials"—(U. S. P.).

Assay (U. S. P.). *Assay of Extract of Opium.*—"Extract of opium, 100° C. (212° F.), four grammes (4 Gm.); ammonia water, two and two-tenths cubic centimeters (2.2 Cc.); alcohol, ether, water, each, a sufficient quantity. Dissolve the extract of opium in 30 Cc. of water, filter the solution through a fast-flowing filter, and wash the filter and residue with water, until all soluble matter is extracted, collecting the washings separately. Evaporate in a tared capsule the washings to a small volume, then add the first filtrate, and evaporate the

weight of 10 Gm. Rotate the concentrated solution about in the capsule the rings of extract are redissolved, pour the liquid into a tared Erlenmeyer having a capacity of about 100 Cc., and rinse the capsule with a few drops of at a time, until the entire solution weighs 15 Gm. Then add 7 Gm. (or Cc.) of alcohol, shake well, add 20 Cc. of ether, and shake again. Now add the morphia water from a graduated pipette or burette, stopper the flask with a sound stopper, shake it thoroughly during 10 minutes, and then set it aside, in a moderate cool place, for at least 6 hours, or over night.

Remove the stopper carefully, and, should any crystals adhere to it, brush into the flask. Place in a small funnel 2 rapidly-acting filters of a diameter 1 in., plainly folded, one within the other (the triple fold of the inner filter laid against the single side of the outer filter), wet them well with ether, and pass the ethereal solution as completely as possible upon the inner filter. Add 10 Cc. of ether to the contents of the flask, rotate it, and again decant the ethereal solution upon the inner filter. Repeat this operation with another portion of 10 Cc. of ether. Then pour into the filter the liquid in the flask, in portions, in such a way as to transfer the greater portion of the crystals to the filter, and, when the liquid has passed through, transfer the remaining crystals to the filter by washing the flask with several portions of water, using not more than about 10 Cc. in all. Remove the double filter to drain, then apply water to the crystals, drop by drop, until they are practically free from mother-water, and afterwards wash them, drop by drop, from a pipette, with alcohol previously saturated with powdered morphia. When this has passed through, displace the remaining alcohol by ether, using about 10 Cc., or more, if necessary. Allow the filter to dry in a moderately warm place at a temperature not exceeding 60° C. (140° F.), until its weight is constant, then carefully transfer the crystals to a tared watch-glass and weigh them. The weight found, multiplied by 25, represents the amount of crystallized morphia obtained from 100 Gm. of the extract"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Opium*). This is essentially a purified extract, the inert matter having been removed in its preparation. It has been found that many persons who can not take the crude drug without experiencing many unpleasant symptoms, can take the extract without its being counteracted by any of these symptoms. The dose is $\frac{1}{4}$ to $\frac{1}{2}$ grain. The extract may be combined with other extracts, and may, if desired, be dissolved in water.

EXTRACTUM OPII LIQUIDUM.—LIQUID EXTRACT OF OPIUM.

Preparation.—The *British Pharmacopœia* directs the preparation of this fluid extract of opium as follows: "Take of extract of opium 1 ounce (av.), distilled water 16 fluid ounces, rectified spirit 4 fluid ounces. Macerate the extract of opium in the water for an hour, stirring frequently; then add the spirit and stir. The product should measure 1 pint (Imp). It contains 22 grains of extract of opium, nearly, in 1 fluid ounce. Sp. gr., from 0.985 to 0.995"—(*Br. Ph.*). In point of non-nauseating qualities this preparation is superior to other liquid preparations of opium, except the deodorized tincture of opium. This preparation contains those principles of opium soluble in water, and is preserved by the presence of the alcohol, which proportion, according to some pharmacists, should be somewhat increased to give it greater stability.

Medical Uses and Dosage.—Uses, same as *Opium*. Dose, 10 to 30 minims.

EXTRACTUM PAPAVERIS.—EXTRACT OF POPPY.

Preparation.—"Take of poppy capsules, freed from the seeds, and in No. 20 powder, 1 pound (av.); rectified spirit, 2 ounces (Imp.); boiling distilled water, a deficiency. Mix the poppy capsules with 2 pints of the water, and infuse for 48 hours, stirring frequently; then pack in a percolator, and, adding more of the water, allow the liquor slowly to pass until about a gallon has been collected, or until the residue is exhausted. Evaporate the liquor by a water-bath until it is reduced to a pint, and, when cold, add the spirit. Let the mixture stand for 24 hours, then separate the clear liquor by filtration, and evaporate this by a

water-bath until the extract has acquired a suitable consistence for forming pills"—(*Br. Pharm.*). This preparation is seldom employed in America.

Medical Uses and Dosage.—(*See Papaveris Capsulæ*). Dose, 2 to 5 grains.

EXTRACTUM PAREIRÆ.—EXTRACT OF PAREIRA.

Preparation.—"Take of pareira root, in No. 40 powder 1 pound (av.), boiling distilled water, a sufficiency. Digest the pareira root with a pint of the water for 24 hours, then pack in a percolator, and, adding more of the water, allow the liquor slowly to pass until about a gallon has been collected, or the pareira is exhausted. Evaporate the liquor by a water-bath until the extract has acquired a suitable consistence for pills"—(*Br. Ph.*).

Medical Uses and Dosage.—(*See Pareira*). A diluted alcoholic menstruum will, in our opinion, make a better preparation, and one freer from inert matter. Dose, 10 to 30 grains.

EXTRACTUM PAREIRÆ FLUIDUM (U. S. P.)—FLUID

EXTRACT OF PAREIRA.

Preparation.—"Pareira, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl̄z, 183 M]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄z, 391 M]. Mix the glycerin with seven hundred and twenty cubic centimeters (720 Cc.) [24 fl̄z, 66 M] of alcohol, and one hundred and eighty cubic centimeters (180 Cc.) [6 fl̄z, 42 M] of water, and having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄z, 252 M] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward a mixture of alcohol and water, made in the proportion of four hundred cubic centimeters (400 Cc.) [13 fl̄z, 252 M] of alcohol, to one hundred cubic centimeters (100 Cc.) [3 fl̄z, 183 M] of water, until the pareira is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄z, 356 M] of the percolate. Distill off the alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄z, 391 M]"—(*U. S. P.*).

Description, Medical Uses, and Dosage.—(*See Pareira*). This is a brown, bitter fluid. A weaker alcoholic menstruum is said to produce as efficient a product. We question the usefulness of the glycerin. Dose, 15 to 90 minims, largely diluted.

EXTRACTUM PETROSELINI RADICIS FLUIDUM (N. F.)—FLUID

EXTRACT OF PARSLEY ROOT

Preparation.—*Formulary number, 171*: "From the root of *Petroselinum sativum*, Hoffmann (*Parsley*). *Process A* (see F. 135). No. 40 powder. *Menstruum*: Diluted alcohol"—(*Nat. Form.*). Commercial parsley root is prone to injury by insects. Care should be exercised in the selection of the drug, and market-ground parsley root should be excluded if the whole root is to be had.

Medical Uses and Dosage.—(*See Petroselinum*). Dose, 10 to 60 minims.

EXTRACTUM PHYSOSTIGMATIS (U. S. P.)—EXTRACT OF PHYSOSTIGMA.

SYNONYM: *Extract of calabar bean.*

Preparation.—"Physostigma, in No. 80 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity. Moisten

the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 M.] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol until three thousand cubic centimeters (3000 Cc.) [101 fl̄, 212 M.] of tincture are obtained, or the physostigma is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 M.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M.]; mix this with the reserved portion, and evaporate, at or below the before-mentioned temperature, on a water-bath, to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Physostigma*). In the preparation of this extract, the menstruum directed in the official process should be strictly adhered to. Diluted alcohol produces a greater yield of extract, but at its alkaloidal expense. Extract of physostigma well represents calabar bean, and is of a green-brown color. Dose, $\frac{1}{16}$ to $\frac{1}{8}$ grain.

EXTRACTUM PHYTOLACCÆ.—EXTRACT OF POKE.

Preparation.—Exhaust the recently dried leaves of poke, in coarse powder, with diluted alcohol, a sufficient quantity, proceeding in the same manner as explained for the preparation of Alcoholic Extracts, on page 758. Extract of poke prepared in this manner, is superior to that prepared in the ordinary way with water. The leaves employed in the preparation of the extract should be gathered immediately previous to the ripening of the berries, at which period they are the most active. An extract is prepared from the poke-root in the same manner. An extract formed by evaporating the expressed juice of the recent ripe berries is frequently employed, and has been recently highly lauded as an antifat.

Medical Uses and Dosage.—These various extracts of poke are emetic and purgative in large doses; in medicinal doses they are alterative, and are especially useful in *syphilitic*, *mercurio-syphilitic*, and *rheumatic diseases*, and particularly in the *osteocopic pains of mercurio-syphilis*. They lose their virtues by age, and should be freshly prepared every year. The dose is from 1 to 5 grains, or more, 3 times a day. The inspissated juice of poke-berries (*Succus inspissatus phytolacæ baccæ*), is frequently employed as a valuable agent in *rheumatism*; it is milder than the extract prepared from the root or leaves. The dose, both as an antifat and in rheumatism, is from 2 to 5 grains 3 times daily. Since, so far as we know, all advertised antifat remedies are given by specialists in connection with heavy doses of cathartics, the inference is that the *cathartic* deserves the credit for the loss of flesh.

EXTRACTUM PHYTOLACCÆ RADICIS FLUIDUM (U. S. P.) FLUID EXTRACT OF PHYTOLACCA ROOT.

SYNONYM: *Fluid extract of poke-root.*

Preparation.—“Phytolacca root, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]. Mix six hundred cubic centimeters (600 Cc.) [20 fl̄, 188 M.] of alcohol with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 M.] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 M.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder, and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before until the phytolacca root is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 M.] of the percolate, and evaporate the remainder,

at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstrum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M].—(U. S. P.).

Medical Uses and Dosage.—As poke-root is of little value unless fresh, it is very probable that this preparation will be of little value in therapy. Dose, from 5 to 10 minims, 3 or 4 times a day.

EXTRACTUM PILOCARPI FLUIDUM (U. S. P.)—FLUID EXTRACT OF PILOCARPUS.

SYNONYM: *Fluid extract of jaborandi.*

Preparation.—"Pilocarpus, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 oza., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Moisten the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 M] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the pilocarpus is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 M] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M].—(U. S. P.).

In our experience, a preparation to be preferred when its keeping qualities are considered, is made with official alcohol only as the menstrum. We therefore introduce the following process from our Supplement, 1881:

EXTRACTUM PILOCARPI PENNATIFOLII FLUIDUM, *Fluid extract of Pilocarpus pennatifolius, Fluid extract of jaborandi.*—Take of jaborandi leaves, in very fine powder, 16 troy ounces; of alcohol and acetic acid, each, a sufficient quantity. Moisten the powdered leaves with a mixture of 6 fluid ounces of alcohol and 2 fluid drachms of acetic acid. Cork tightly in a wide-mouth bottle, and permit the mixture to stand an hour in a warm situation. Then introduce it into a cylindrical percolator 3 inches in diameter, previously prepared for percolation, according to directions given on page 756, and press very firmly. Cover the surface of the powder with a circular piece of filtering paper, held in position with a few fragments of glass or marble, and add alcohol until the percolate appears at the exit. Then cork the exit tightly; cover the percolator, and place it in a warm situation. After 24 hours loosen the cork, and permit the percolate to pass as fast as it will drop without running in a stream, until 4 fluid ounces are obtained. Again close the exit macerate 24 hours, and, in a manner like unto the preceding, draw 4 fluid ounces of percolate. Repeat the maceration, and, in like manner, draw a third portion of 4 fluid ounces. Reserve and mix the three percolates; then continue the percolation until 8 fluid ounces are obtained. Evaporate this latter portion until reduced to the measure of 2 fluid ounces, and mix with the reserved 12 fluid ounces. The surface of the powder must be constantly covered with alcohol from the commencement, and until the end of the process of percolation.

Description, Medical Uses, and Dosage.—(See *Pilocarpus*). Fluid extract of jaborandi, when prepared with alcohol and acetic acid, is dark-green in color, almost odorless, possesses the taste of the drug, and, as thus prepared, represents very nearly the quality of the drug employed, troy ounce to each fluid ounce of the finished extract. If the fluid extract be made as in the official process, with mixtures of water and alcohol, the dark-colored extractive matters of the leaves are dissolved, and the extract will have a dark reddish-brown color, is more given to precipitation, but will not be as satisfactory as though made with alcohol, either from a pharmaceutical or a therapeutical point of view. The addition of the acetic acid favors the extraction of the pilocarpine, and by using it in connection with alcohol, both the volatile oil and alkaloid of the drug are dissolved. Dose, 1 to 15 minims.

EXTRACTUM PIPERIS METHYSTICI FLUIDUM.—FLUID EXTRACT OF PIPER METHYSTICUM.

Preparation.—Take of the root of *Piper methysticum*, in moderately fine powder, 16 troy ounces; of a menstruum of alcohol, 3 parts, water, 2 parts (by measure), a sufficient quantity. Moisten the powdered root with 6 fluid ounces of the menstruum. Cork tightly in a wide-mouth bottle, and permit the mixture to stand an hour in a warm situation. Then introduce it into a cylindrical percolator, 3 inches in diameter, previously prepared for percolation according to directions given on page 756, and press moderately. Cover the surface of the powder with a circular piece of filtering paper, held in position with a few fragments of glass or marble, and add fresh menstruum until the percolate appears at the exit. Then cork the exit tightly; cover the percolator, and place it in a warm situation. After 24 hours, loosen the cork, and permit the percolate to pass as fast as it will drop, without running in a stream, until 4 fluid ounces are obtained. Again close the exit, macerate 24 hours, and, in a manner like unto the preceding, draw 4 fluid ounces of percolate. Repeat the maceration, and, in like manner, draw a third portion of 4 fluid ounces. Reserve and mix the 3 percolates; then continue the percolation until 8 fluid ounces are obtained. Evaporate this latter portion until reduced to the measure of 2 fluid ounces, and mix with the reserved 12 fluid ounces. The surface of the powder must be constantly covered with menstruum from the commencement, and until the end of the process of percolation.

Description, Medical Uses, and Dosage.—(See *Piper methysticum*). Fluid extract of *Piper methysticum* is of a reddish-brown color, and imparts the taste of the root. It is odorless, and, as thus prepared, represents very nearly the quality of drug employed, troy ounce to each fluid ounce of the finished extract. This is our formula, introduced in the Supplement in 1881. The *National Formulary* practically directs the above menstruum and process.

EXTRACTUM PLANTAGINIS CORDATÆ.—EXTRACT OF PLANTAGO CORDATA.

SYNONYM: *Extract of water plantain.*

Preparation.—Exhaust the recently dried root of water plantain, in coarse powder, with alcohol, water, each, a sufficient quantity, proceeding in the same manner as explained for the preparation of *Extractum Hydrastis*.

Medical Uses and Dosage.—Hydro-alcoholic extract of water plantain is astringent, and has been used with much success in *Asiatic cholera*, *diarrhœa*, and *dysentery*. The dose is from 1 to 10 grains, repeated every 1, 2, or 3 hours, as the urgency of the case requires (Wm. S. Merrell).

EXTRACTUM PODOPHYLLI (U. S. P.)—EXTRACT OF PODOPHYLLUM.

SYNONYMS: *Extract of mandrake, Extract of May apple.*

Preparation.—“Podophyllum, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity. Mix eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of alcohol with two hundred cubic centimeters (200 Cc.) [8 fl̄, 366 m̄] of water, and, having moistened the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the podophyllum is exhausted. Distill off the alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence”—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a dark-brown or an alterative, this may be given in doses of from $\frac{1}{2}$ to 2 or 3 grains: or from 3 to 12 grains. It may be used as a substitute for jalap in all cases where a purgative is required. Although not so active as an extract made in alcohol, it is more useful.

EXTRACTUM PODOPHYLLI FLUIDUM (U. S. P.)—FLUID EXTRACT OF PODOPHYLLUM.

SYNONYMS: *Fluid extract of May apple, Fluid extract of mandarin.*

Preparation.—“Podophyllum, in No. 60 powder, one thousand grains (Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. oz., 391 M.] of alcohol with five hundred cubic centimeters (500 Cc.) [27 fl. oz., 25 M.] of alcohol with two hundred cubic centimeters (200 Cc.) [6 fl. oz., 366 M.] of water, and, having mixed the powder with three hundred cubic centimeters (300 Cc.) [10 fl. oz., 67 M.] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid has passed a drop from the percolator, close the lower orifice, and, having closely stoppered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the podophyllum is exhausted. Reserve the first eight hundred cubic centimeters (850 Cc.) [28 fl. oz., 356 M.] of the percolate. Evaporate the alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl. oz., 391 M.]”—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a deep brownish-yellow liquid. It is not much valued in therapy. Dose, 5 to 20 minims.

EXTRACTUM POLYGONI.—EXTRACT OF POLYGONUM.

SYNONYM: *Extract of water pepper.*

Preparation.—Exhaust the recently dried herb of water pepper with alcohol, with water, a sufficient quantity, proceeding in the manner directed for the preparation of Aqueous Extracts, on page 758.

Medical Uses and Dosage.—Extract of water pepper is stimulant and emmenagogue, and is especially useful in *amenorrhœa* and *chronic catarrhs of the kidneys*. It is devoid of the pepper taste of fresh water pepper, which is too evanescent to withstand such manipulation. The dose is from 2 to 3 or 4 times a day.

EXTRACTUM POLYGONI FLUIDUM.—FLUID EXTRACT OF POLYGONUM.

SYNONYM: *Fluid extract of water pepper.*

Preparation.—Take of the recently dried leaves of water pepper powder, 16 troy ounces; alcohol, diluted alcohol, each, a sufficient quantity. Moisten the leaves thoroughly with alcohol, and let them stand for 24 hours; then transfer them to a percolator, and gradually add alcohol, returning a little of the first that comes through, till it passes clear. Reserve, by itself, of the percolate, 12 fluid ounces; then gradually add a sufficient quantity of diluted alcohol to the residuum in the percolator, until the liquid that comes through is almost colorless, little of the color or taste of the water pepper. Evaporate this latter portion to 4 fluid ounces, and, while warm, mix in the reserved tincture, and make up to 16 fluid ounces.

Medical Uses and Dosage.—Fluid extract of water pepper possesses the virtues of the dry herb, and may be given whenever that drug is indicated. It is especially useful in *uterine diseases*. The dose is from 10 to 60 minims, 3 or 4 times a day.

EXTRACTUM POLYMNIAE FLUIDUM.—FLUID**EXTRACT OF POLYMNIA.**

NONYMS: *Fluid extract of uvedalia, Fluid extract of bear's foot.*

Preparation.—Take of the root of *Polymnia uvedalia*, in moderately fine powder, 16 troy ounces; alcohol, a sufficient quantity. Moisten the powder with 4 fluid ounces of alcohol. Cork tightly in a wide-mouth bottle, and permit the bottle to stand an hour in a warm situation. Then introduce it into a cylindrical percolator, 3 inches in diameter, previously prepared for percolation, according to the directions given on page 756, and press very firmly. Cover the surface of the powder with a circular piece of filtering paper, held in position with a few fragments of glass or marble, and add alcohol until the percolate appears at the exit. Cork the exit tightly, cover the percolator, and place it in a warm situation. After 24 hours, loosen the cork, and permit the percolate to pass as fast as it will without running in a stream, until 4 fluid ounces are obtained. Again close the percolator, macerate 24 hours, and, in a manner like unto the preceding, draw 4 fluid ounces of percolate. Repeat the maceration, and, in like manner, draw a second portion of 4 fluid ounces. Reserve and mix the 3 percolates; then continue the percolation until 8 fluid ounces are obtained. Evaporate this latter portion of percolate reduced to the measure of 2 fluid ounces, and mix with the reserved 12 fluid ounces. The surface of the powder must be constantly covered with alcohol from the commencement, and until the end of the process of percolation.

Description, Medical Uses, and Dosage.—Fluid extract of *Polymnia uvedalia* is reddish-brown in color, of a disagreeable fetid odor and taste, and, as thus prepared, represents very nearly the quality of the drug employed, troy ounce to fluid ounce of the finished extract. Any addition of water or glycerin to the alcohol composing the menstruum, is to be avoided, as they occasion loss of its constituents. (For uses, see *Polymnia*). Dose, 10 to 60 minims.

**EXTRACTUM PRUNI VIRGINIANÆ.—EXTRACT OF
WILD CHERRY.**

Preparation.—Take of wild cherry bark, in coarse powder, alcohol, a sufficient quantity. Moisten the bark with a pint of alcohol, let it stand 24 hours, then transfer to a displacement apparatus, and gradually add alcohol until it passes off tasteless. Evaporate by a gentle heat, or spontaneously; too great a degree of heat will spoil the extract. Wild cherry bark yields to alcohol 22 per cent of deep-red, bitter, astringent extract, containing amygdalin.

Medical Uses and Dosage.—It has been suggested that this extract may be rendered available for extemporaneous prescriptions in the following manner, to get the sedative power of the bark associated with all its tonic qualities.

Take of alcoholic extract of wild cherry bark, 2 drachms; emulsion of almonds, $\frac{1}{2}$ pint; triturate the extract with a portion of the emulsion till dissolved, and then add the remainder and mix. It should not be used for several hours after it is prepared. The dose is a tablespoonful, and it may be sweetened with sugar or syrup. Before administration it must be shaken, as the album formed by the tannin of the extract acting on the albumen of the emulsion is not to be removed (W. Procter, Jr.).

**EXTRACTUM PRUNI VIRGINIANÆ FLUIDUM (U. S. P.)—FLUID
EXTRACT OF WILD CHERRY.**

Preparation.—“Wild cherry, in No. 20 powder, one thousand grammes (1000 g.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, one hundred cubic centimeters (100 cc.) [3 fl. oz., 183 m.]; alcohol, water, each a sufficient quantity to make one thousand cubic centimeters (1000 cc.) [33 fl. oz., 391 m.]. Mix the glycerin with two dried cubic centimeters (200 cc.) [6 fl. oz., 366 m.] of water, and, having moistened the powder with the mixture, pack it firmly in a cylindrical glass percolator,

and, having closely covered the percolator, macerate for 48 hours; then gradually add menstruum, made in the proportion of eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 m̄] of alcohol to one hundred and fifty cubic centimeters (150 Cc.) [5 fl̄, 35 m̄] of water, and allow the percolation to proceed until the wild cherry is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Prunus Virginiana*). This preparation has been the subject of constant change of formula in each succeeding Pharmacopœia. The present formula is thought to be an improvement upon all of its predecessors. However, barring its troublesome manipulation, the modified formula of Prof. W. Procter, Jr., has been considered by competent judges an excellent preparation. Procter's process will be found below. This extract is a dark, wine-red, transparent liquid, not syrupy in consistence, and possessed of a bitter, hydrocyanic taste. If it be desired to make a preparation free from astrin-gency, strips of isinglass, previously softened in water, may be added to the aqueous solution, which will remove the tannic acid.

This may be used wherever wild cherry bark is indicated. One fluid drachm of it represents 30 grains of the bark, 2 fluid ounces of the infusion, or a tablespoonful of the syrup. Four fluid ounces of this fluid extract may be added to 12 fluid ounces of simple syrup to form a syrup of wild cherry bark. Dose, 10 to 60 minims.

Procter's Formula.—**FLUID EXTRACT OF WILD CHERRY.** Take of wild cherry bark, 24 troy ounces; sweet almonds, 3 troy ounces; pure granulated sugar, 36 troy ounces; alcohol, 88 per cent, and water, each, a sufficient quantity. Macerate the powdered bark in 2 pints of alcohol for 8 hours, introduce it into a percolator and pour on alcohol till 5 pints have passed, observing to regulate the passage of the liquid by a cork or stop-cock. Introduce the tincture into a capsule (or distillatory apparatus, if the alcohol is to be regained), and evaporate it to a syrupy consistence; add $\frac{1}{2}$ pint of water, and again evaporate till the alcohol is entirely removed. Beat the almonds, without blanching, into a smooth paste with a little of the water, and then add sufficient to make the emulsion measure $1\frac{1}{2}$ pints, and pour it in a quart bottle previously containing the solution of the extract of the bark, cork it securely, and agitate occasionally for 24 hours, so as to give time for the decomposition of the amygdalin. The mixture is then to be quickly expressed and filtered into a bottle containing the sugar, marked to hold 3 pints. Water should be added to the dregs, and they again expressed till sufficient filtered liquid is obtained to make the fluid extract measure 3 pints (W. Procter, Jr.). A superior fluid extract of wild cherry, may be made by freely moistening the coarse powdered bark, 16 troy ounces, and sweet almonds, beaten to a paste with just enough water, $1\frac{1}{2}$ troy ounces, with a mixture of equal parts of glycerin and water; cover and let them macerate for 4 days; pack uniformly in a percolator, and gradually add of the mixture of equal parts of glycerin and water, until 11 fluid ounces have been used altogether. Then gradually add alcohol until enough has passed to make the whole amount of fluid extract equal to 1 pint. It will be seen that this process is a modification of the formula of Prof. Procter, the advantage being that the manipulation is more simple. The dose of these extracts is that of the official preparation.

EXTRACTUM PTELEÆ.—EXTRACT OF PTELEA.

SYNONYM: *Alcoholic extract of shrubby trefoil.*

Preparation.—Exhaust the recently dried bark of the root of *Ptelea trifoliata*, in coarse powder, with alcohol, proceeding in the manner explained for the preparation of Alcoholic Extracts, on page 758.

Medical Uses and Dosage.—This extract is an elegant preparation, and may be used in all cases where ptelea is indicated. The addition of water to the alcohol injures the preparation. The dose is from 2 to 10 grains.

EXTRACTUM QUASSIÆ (U. S. P.).—EXTRACT OF QUASSIA.

Preparation.—“Quassia, in No. 20 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; water, a sufficient quantity. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of water, pack it firmly in a conical percolator, and gradually pour water upon it until the infu-

sion passes but slightly imbued with bitterness. Reduce the liquid to $\frac{2}{3}$ of its bulk by boiling, and strain; then evaporate, by means of a water-bath, to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a concentrated, deep-brown or black, bitter extract, becoming dry and crumbling with age. Dose, usually with other bitter tonics, 1 to 2 grains.

EXTRACTUM QUASSIÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF QUASSIA.

Preparation.—"Quassia, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of alcohol with six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 m̄] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the quassia is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Quassia*). This is a brownish-yellow, persistently bitter fluid. The dose is from 5 to 20 minims, well diluted with water.

EXTRACTUM QUILLAJÆ FLUIDUM (N. F.)—FLUID EXTRACT OF QUILLAJA.

Preparation.—*Formulary number, 172:* "From the bark of *Quillaja Saponaria*, Molina (*Soap bark*). *Process A* (see F. 135). No. 40 powder. *Menstruum:* Diluted alcohol"—(Nat. Form.).

Medical Uses and Dosage.—(See *Quillaja*). This preparation is used mainly to produce froth in beverages. A few drops will make soda syrups foam liberally. Dose, 1 to 20 minims.

EXTRACTUM RHAMNI PURSHIANÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF RHAMNUS PURSHIANA.

SYNONYM: *Fluid extract of cascara sagrada.*

Preparation.—"Rhamnus purshiana, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the rhamnus purshiana is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—Fluid extract of *Rhamnus purshiana* is dark yellowish-red in color, almost odorless, of a disagreeable bitter taste,

and, as thus prepared, represents very nearly the quality of drug emulsion to each fluid ounce of the finished extract. This preparation, official for the first time, is extensively used as a remedy for *habitual constipation*. It was introduced through the efforts of Parke, Davis & Co., who gave it the conspicuousity and liberal advertisements. The drug was first mentioned by Bundy, but the conspicuity of the fluid extract is clearly to be credited to the energetic firm. Dose, 10 to 45 minims.

EXTRACTUM RHAMNI PURSHIANÆ FLUIDUM AROMATICUM

(N. F.)—AROMATIC FLUID EXTRACT OF RHAMNUS PURSHIANÆ

SYNONYM: *Aromatic fluid extract of cascara sagrada.*

Preparation.—*Formulary number, 173:* "Rhamnus purshiana, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; magnesia, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 2 1/2 ozs. troy]; glycerin, two hundred and fifty cubic centimeters (250 Cc.) [8 fl. oz., 2 1/2 pints]; pound spirit of orange (U. S. P.), ten cubic centimeters (10 Cc.) [168 minims]; five hundred cubic centimeters (500 Cc.) [16 fl. oz., 435 minims]; water, diluted (U. S. P.), each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl. oz., 391 minims]. Mix the powdered drugs and the magnesia with the water, macerate for 48 hours and then dry the mixture on a water-bath at a gentle heat. Mix the alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl. oz., 218 minims] of water, and percolate the dried powders with this menstruum by diluted alcohol, according to the directions given under *Process B*. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [26 fl. oz., 356 minims] that pass, and set this aside. Continue the percolation with the alcohol to practical exhaustion, evaporate this second portion to a soft extractum in the reserved portion, and add the compound spirit of orange and diluted alcohol to make one thousand cubic centimeters (1000 Cc.) [33 fl. oz. of fluid extract]"—(*Nat. Form.*).

Medical Uses and Dosage.—An agreeable aromatic laxative. Dose, 10 to 45 minims.

Under the name of *Cascara Cordial*, Parke, Davis & Co. have long made a palatable preparation of cascara, which enjoys the confidence of those who use it. *Kasagra*, or *Cascara Aromatica*, is a liquid preparation of cascara sagrada, extensively used by physicians, made by Frederick Stearns & Co., of Detroit. Both preparations are very pleasant to the taste, being destitute of all bitterness.

EXTRACTUM RHEI (U. S. P.)—EXTRACT OF RHUBARB

Preparation.—"Rhubarb, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [27 fl. oz., 25 minims] of alcohol with two hundred cubic centimeters (200 Cc.) [6 fl. oz., 366 minims] of water, and, having added the powder with four hundred cubic centimeters (400 Cc.) [13 fl. oz., 252 minims] of water, pack it firmly in a conical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to flow from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, adding menstruum, using the same proportions of alcohol and water, until the tincture passes nearly tasteless. Reserve the first one thousand cubic centimeters (1000 Cc.) [33 fl. oz., 391 minims] of the percolate, and set it aside in a place, until it is reduced by spontaneous evaporation to five hundred cubic centimeters (500 Cc.) [16 fl. oz., 435 minims]. Evaporate the remainder of the percolate in a porcelain vessel, by means of a water-bath, at a temperature not exceeding 158° F., to the consistence of syrup. Mix this with the reserved portion."

continue the evaporation, at or below the before-mentioned temperature, until the mixture is reduced to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Rheum*). Great care is required in the preparation of this extract, as both the tonic and purgative properties of rhubarb are very apt to become deteriorated by the process. Only a gentle heat must be employed. The extract prepared by evaporation in vacuo, will be found decidedly the best; it possesses the odor and taste of the root. Extract of rhubarb, only when well and carefully prepared, possesses virtues similar to the drug itself, and may be given in pill form, or in solution in doses of from 5 grains to $\frac{1}{2}$ drachm.

EXTRACTUM RHEI FLUIDUM (U. S. P.)—FLUID EXTRACT OF RHUBARB.

Preparation.—"Rhubarb, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M̄]. Mix eight hundred cubic centimeters (800 Cc.) [27 fl̄3, 25 M̄] of alcohol with two hundred cubic centimeters (200 Cc.) [6 fl̄3, 366 M̄] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄3, 252 M̄] of the mixture, pack it firmly in a conical percolator; then add enough of menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the rhubarb is exhausted. Reserve the first seven hundred and fifty cubic centimeters (750 Cc., [25 fl̄3, 173 M̄] of the percolate, and evaporate the remainder, at a temperature not exceeding 70° C. (158° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄3, 391 M̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Rheum*). This is a very dark red-brown liquid, possessing the characteristic taste and odor of rhubarb. This product remains fluid for a much longer period than those formerly official, in which sugar, glycerin, etc., were employed. Precipitation is likely to occur by age. This is an efficient preparation, fairly representative of the virtues of the rhubarb, and may be administered in all cases where that drug is admissible. The dose for an adult is from $\frac{1}{4}$ to 1 fluid drachm, which are equivalent to similar quantities of the root. When it is desired to disguise the taste, in cases where stimulants are not contraindicated, 6 or 8 fluid drachms may be added to 8 fluid ounces of the above, of a mixture composed of equal parts of tincture of prickly-ash berries, tincture of ginger, and essence of sassafras.

EXTRACTUM RHOIS AROMATICÆ FLUIDUM.—FLUID EXTRACT OF RHUS AROMATICA.

Preparation.—Take of the bark of the root of *Rhus aromatica*, in fine powder, 16 troy ounces; alcohol, a sufficient quantity. Moisten the powder with 6 fluid ounces of alcohol. Cork tightly in a wide-mouth bottle, and permit the mixture to stand an hour in a warm situation. Then introduce it into a cylindrical percolator, 3 inches in diameter, previously prepared for percolation according to directions given on page 756, and press very firmly. Cover the surface of the powder with a circular piece of filtering paper, held in position with a few fragments of glass or marble, and add alcohol until the percolate appears at the exit. Then cork the exit tightly; cover the percolator, and place it in a warm situation. After 24 hours, loosen the cork, and permit the percolate to pass as fast as it will drop without running in a stream, until 4 fluid ounces are obtained. Again close the exit, macerate 24 hours, and, in a manner like unto the preceding, draw 4 fluid ounces of percolate. Repeat the maceration, and, in like manner, draw a third portion of 4 fluid ounces. Reserve and mix the three percolates, then continue the percolation until 8 fluid ounces are obtained. Evaporate this latter

portion until reduced to the measure of 2 fluid ounces, and mix with the reserved 12 fluid ounces. The surface of the powder must be constantly covered with alcohol from the commencement, and until the end of the process of percolation.

Description, Medical Uses, and Dosage.—Fluid extract of *Rhus aromatica* is of a brownish color, and possesses the disagreeable, turpentine-like odor and taste of the root. It should not be made with a menstruum containing water or glycerin, as these bodies prevent the resinous constituents of the root from dissolving. As prepared by the foregoing formula, the extract represents very nearly those constituents of the root soluble in alcohol, troy ounce to fluid ounce. For uses, see *Rhus aromatica*. Dose, 5 to 60 minims, in water, glycerin and water, or syrup.

EXTRACTUM RHUS GLABRÆ FLUIDUM (U. S. P.)—FLUID

EXTRACT OF RHUS GLABRA

SYNONYM: *Fluid extract of sumach-berries.*

Preparation.—“*Rhus glabra*, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 m̄]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix the glycerin with nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of diluted alcohol, and, having moistened the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards diluted alcohol, until the *rhus glabra* is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Rhus glabra*). This agent is of a dark-red color, and has the agreeably acidulous and constringing taste of the berries from which it is prepared. (For *fluid extract of the bark*, see below.) Fluid extract of sumach is tonic, astringent, and antiseptic. It will be found beneficial in *scrofula*, *gonorrhœa*, *diarrhœa*, *dysentery*, and in *mercurial sore mouth* and *salivation*. The dose is from $\frac{1}{2}$ fluid drachm to 1 fluid drachm, 3 times a day.

Related Preparation.—FLUID EXTRACT OF RHUS GLABRA BARK, *Fluid extract of sumach bark*. Take of the recently dried bark of *Rhus glabra*, in coarse powder, 16 troy ounces; alcohol, diluted alcohol, each, a sufficient quantity. Add sufficient alcohol to the bark to thoroughly moisten it, and let it macerate for 24 hours; then transfer the mixture to a percolator, and gradually add alcohol, returning a little of the first that passes, till it runs clear. Reserve by itself, of the first percolate 12 fluid ounces. Then pour diluted alcohol on the residuum in the percolator, until the liquid that passes has very little of the taste of the sumach; evaporate this latter solution to 4 fluid ounces, and while warm mix in the reserved tincture and extract, and make 1 pint of fluid extract. Used same as the preceding.

EXTRACTUM ROSÆ FLUIDUM (U. S. P.)—FLUID

EXTRACT OF ROSE.

SYNONYM: *Fluid extract of red rose.*

Preparation.—“Red rose, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 m̄]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix the glycerin with nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of diluted alcohol, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When

the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward diluted alcohol, until the red rose is exhausted. Reserve the first seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 m̄] of the percolate, and evaporate the remainder in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]—(U. S. P.).

Description, Medical Uses, and Dosage.—This fluid has a deep-red color, and the odor of rose. To the taste it is pleasantly subastringent. It may be added to mouth washes and gargles, and employed to disguise the taste of magnesium and sodium sulphates, etc. Dose, 30 minims to 2 fluid drachms

EXTRACTUM RUBI FLUIDUM (U. S. P.)—FLUID EXTRACT OF RUBUS.

SYNONYM: *Fluid extract of blackberry bark.*

Preparation.—“Rubus, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 m̄]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix the glycerin with six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 m̄] of alcohol and three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of water, and, having moistened the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward a mixture of alcohol and water, made in the proportion of six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 m̄] of alcohol and three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of water, until the rubus is exhausted. Reserve the first seven hundred cubic centimeters (700 Cc.) [23 fl̄, 321 m̄] of the percolate. Distill off the alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough of the mixture of alcohol and water, using the last-named proportions, to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]—(U. S. P.).

Description, Medical Uses, and Dosage.—A strongly astringent, dark red-brown, translucent liquid. Dose, 30 minims to 2 fluid drachms.

EXTRACTUM RUMICIS.—EXTRACT OF RUMEX.

SYNONYM: *Extract of yellow dock.*

Preparation.—Exhaust coarsely powdered yellow dock root, with alcohol, water, each, a sufficient quantity, proceeding in the manner explained for the preparation of Alcoholic Extracts, on page 758 (E. S. Wayne).

Medical Uses and Dosage.—This extract is tonic and alterative, and is efficient in *scrofula* and *cutaneous diseases*. It is most generally given in combination with some other alterative, as extract of poke, cimicifuga, dulcamara, corydalis, etc. The dose is from 1 to 5 grains, 3 times a day.

EXTRACTUM RUMICIS FLUIDUM (U. S. P.)—FLUID EXTRACT OF RUMEX.

SYNONYM: *Fluid extract of yellow dock.*

Preparation.—“Rumex, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 oz., 120 grs.]; diluted alcohol, a sufficient quantity to make one

thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol until the rumex is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Rumex*). This dark reddish-brown fluid has a bitter and astringent taste, and well represents the crude drug. Dose, 10 to 60 minims.

EXTRACTUM SABINÆ FLUIDUM (U. S. P.)—FLUID

EXTRACT OF SAVINE.

Preparation.—"Savine, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the savine is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.) to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Sabina*). This preparation contains the active constituents of savine, and has a dark, brownish-green color. It precipitates when mixed with water. Dose, 2 to 15 minims.

EXTRACTUM SANGUINARIÆ.—EXTRACT OF SANGUINARIA.

SYNONYM: *Extract of bloodroot.*

Preparation.—Exhaust coarsely powdered bloodroot, with alcohol, water, each, a sufficient quantity, proceeding in the manner explained for the preparation of Alcoholic Extracts, on page 758.

Medical Uses and Dosage.—This preparation of bloodroot is expectorant, alterative, and emmenagogue, and may be used with benefit in *pulmonary* and *hepatic diseases*, *jaundice*, and *amenorrhœa*. Externally, it forms a mild caustic, and may be advantageously applied to *indolent ulcers* and *fistula-in-ano*. It possesses the virtues of the root. The dose is from $\frac{1}{2}$ to 1 grain (J. King).

EXTRACTUM SANGUINARIÆ FLUIDUM (U. S. P.)—FLUID

EXTRACT OF SANGUINARIA.

SYNONYM: *Fluid extract of bloodroot.*

Preparation.—"Sanguinaria, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lb. av., 3 ozs., 120 grs.]; acetic acid, fifty cubic centimeters (50 Cc.) [1 fl̄, 332 m̄]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix the alcohol and water in the proportion of seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 m̄] of alcohol, and two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄] of water. Moisten the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of the mixture, to which the acetic acid had previously been added,

and let it macerate, in a well-covered vessel, in a warm place, during 48 hours. Then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until the sanguinaria is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Sanguinaria*). This is a deep-red fluid with the tendency, as with all fluid preparations of bloodroot, to precipitation. The formula is improved, in this regard, by using official alcohol instead of alcohol diluted with water, and that, too, without injuring the drug energy of the product. It well represents the crude drug. Dose, from $\frac{1}{4}$ to 5 minims.

EXTRACTUM SARSAPARILLÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF SARSAPARILLA.

Preparation.—“Sarsaparilla, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of alcohol with six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 m̄] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the sarsaparilla is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a somewhat thick, opaque fluid, of a deep red-brown color, and a sweetish and persistent, sub-acrid taste. It is fast losing its popularity as a remedy. Dose, 30 to 60 minims.

EXTRACTUM SARSAPARILLÆ FLUIDUM COMPOSITUM (U. S. P.) COMPOUND FLUID EXTRACT OF SARSAPARILLA.

Preparation.—“Sarsaparilla, in No. 30 powder, seven hundred and fifty grammes (750 Gm.) [1 lb. av., 10 ozs., 199 grs.]; glycyrrhiza, in No. 30 powder, one hundred and twenty grammes (120 Gm.) [4 ozs. av., 102 grs.]; sassafras, in No. 30 powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; mezereum, in No. 30 powder, thirty grammes (30 Gm.) [1 oz. av., 25 grs.]; glycerin, one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 m̄]; alcohol, water, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix the glycerin with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of alcohol and six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 m̄] of water, and, having moistened the mixed powders with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward a mixture of alcohol and water, made in the proportion of three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of alcohol to six hundred cubic centimeters (600 Cc.) [20 fl̄, 138 m̄] of water, until the powder is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 259 m̄] of the percolate,

and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough of a mixture of alcohol and water, using the last-named proportions, to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]—(U. S. P.).

Description, Medical Uses, and Dosage.—This preparation depends for its virtues chiefly upon the mezereum, and the utility of the latter is even questionable. It is intended to replace the compound decoction of sarsaparilla. Inasmuch as the latter contains guaiacum, an active constituent, in our opinion this compound fluid extract is the less efficient of the two. This fluid extract is reputed alterative, and may be used in *acrofula* and *secondary syphilis*. The dose is a fluid drachm, which is equivalent to a drachm of the root, 3 or 4 times a day.

EXTRACTUM SCILLÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF SQUILL.

Preparation.—“Squill, in No. 20 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 M] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 M] of water, and, having moistened the powder with two hundred cubic centimeters (200 Cc.) [6 fl̄, 366 M] of the mixture, pack it in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the squill is exhausted. Reserve the first seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 M] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Scilla*). This preparation has a deep, clear, brown-red color, and a bitter, acrid taste. Alcohol appears to extract the active constituents, though this is best accomplished by the use of diluted acetic acid. It is also suggested that the fluid extract be prepared half strength (*Amer. Drug.*, 1886, p. 202). Dose, 1 to 5 minims, largely diluted with water.

EXTRACTUM SCOPARII FLUIDUM (U. S. P.)—FLUID EXTRACT OF SCOPARIUS.

SYNONYM: *Fluid extract of broom.*

Preparation.—“Scoparius, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Moisten the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 M] of diluted alcohol, and pack firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, using the same proportions of alcohol and water as before, until the scoparius is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 M] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Scoparius*). This is a deep olive-hued liquid of the bitter taste and peculiar odor of broom. An unimportant precipitate may fall. This is intended as a diuretic, but is not so active in this respect as the infusion, and is inferior to that preparation. Dose, 15 to 60 minims.

EXTRACTUM SCUTELLARIÆ.—EXTRACT OF SCUTELLARIA.

SYNONYM: *Extract of scullcap.*

Preparation.—Exhaust the recent dried herb, scullcap, in powder, with diluted alcohol, a sufficient quantity, proceeding in the manner explained for the preparation of Alcoholic Extracts, on page 758.

Medical Uses and Dosage.—(See *Scutellaria*). Extract of scullcap is tonic, nervine, and antispasmodic. It has been used with advantage in cases of *nervous excitability, chorea, wakefulness, and restlessness*; it may be used alone or in combination with the alcoholic extracts of *cimicifuga, cypripedium, or asclepias*. The dose is from 1 to 5 grains, 3 or 4 times a day.

EXTRACTUM SCUTELLARIÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF SCUTELLARIA.

SYNONYM: *Fluid extract of scullcap.*

Preparation.—“*Scutellaria*, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 401 m̄] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the *scutellaria* is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 m̄] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Scutellaria*). This preparation has a dark green-brown color. Diluted alcohol, however, does not produce a very permanent preparation. Fluid extract of scullcap is tonic, nervine, and antispasmodic, and is a very convenient and eligible form of administering the active principles of the plant. It may be used in all cases where the herb is indicated. The dose is from $\frac{1}{4}$ to 1 fluid drachm, 3 or 4 times a day (J. King).

EXTRACTUM SENEGÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF SENEGA

SYNONYM: *Fluid extract of seneka.*

Preparation.—“*Senega*, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lb. av., 3 ozs., 120 grs.]; ammonia water, fifty cubic centimeters (50 Cc.) [1 fl̄, 332 m̄]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix the ammonia water with seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 m̄] of alcohol and two hundred cubic centimeters (200 Cc.) [6 fl̄, 366 m̄] of water, and, having moistened the powder with four hundred and fifty cubic centimeters (450 Cc.) [15 fl̄, 104 m̄] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then a mixture of alcohol and water, made in the proportion of seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 m̄] of alcohol to two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄] of water, until the *senega* is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 m̄] of the percolate, and evaporate the remainder, in a porcelain capsule, to

a soft extract; dissolve this in the reserved portion, and add enough of the last-mentioned mixture of alcohol and water to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a rather thin, deep-brown fluid, having the acrid taste and peculiar odor of senna. Senegin is better extracted by water than by a menstruum strongly alcoholic, though when water is used pectinous matter loads the product so that after a time gelatinization takes place. As a hydro-alcoholic menstruum containing one-third water thoroughly extracts the properties of senna, and with the presence of ammonia to prevent gelatinization, the fluid keeps well, it has been suggested that the official menstruum is unnecessarily too strongly alcoholic. By age, this fluid extract is liable to precipitate a gelatinous substance (pectic acid), which may be redissolved by the cautious addition of a few drops of ammonia water. Fluid extract of senna possesses all the properties of the root, and may be given drachm for drachm, in all cases in which the root is indicated. It may also be added to syrup, honey, and other articles, to form senna syrup, expectorants, etc.

EXTRACTUM SENNÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF SENNA.

Preparation.—“Senna, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 8 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Moisten the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄, 252 M] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol until the senna is exhausted. Reserve the first eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 M] of the percolate, and evaporate the remainder to a soft extract, dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Senna*). In this process, the aromatics and Hoffman's anodyne of former processes are omitted. The earlier preparations were also too thick and gave heavy deposits. Glycerin, added to later processes, did not improve the product, so it is now omitted. When it is desirable to aromatize this fluid extract, add 16 minims of oil of cloves dissolved in $\frac{1}{2}$ fluid ounce of tincture of ginger to the quantity of the formula. If the senna is passed through a sieve 50 or 60 meshes to the inch, and a funnel-shaped percolator be used, the first pint of tincture will contain most of the valuable portion of the senna, and by observing precautions in its evaporation, it is not injured in the process. As the aromatics are omitted, the fluid extract can be employed to make other fluid extracts, tinctures, or syrups, into which senna enters. This forms a neat preparation of senna of a deep-brown color and the characteristic taste and odor of the leaves. An inert precipitate often separates in large amount, and deposits upon the sides and bottom of the container. Dose, 1 to 4 fluid drachms. The purgative dose for an adult is $\frac{1}{2}$ fluid ounce.

EXTRACTUM SENNÆ FLUIDUM DEODORATUM (N. F.) DEODORIZED FLUID EXTRACT OF SENNA.

Preparation.—*Formulary number, 174:* “Senna, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 8 ozs., 120 grs.]; alcohol, water, each a sufficient quantity. Moisten the senna with three hundred and fifty cubic centimeters (350 Cc.) [11 fl̄, 400 M] of alcohol, pack it firmly in a percolator, and percolate it with alcohol until it is practically exhausted by this menstruum. The alcoholic percolate thus obtained is rejected, and the alcohol may be recovered therefrom by distillation. Then take out the moist powder, dry it, and prepare a fluid

extract by the process and menstruum below mentioned: *Process A* (see F. 135), *Menstruum*: Diluted alcohol"—(*Nat. Form.*).

This preparation is intended to carry the laxative qualities of senna without the griping constituents. These are removed by the preliminary percolation by means of alcohol.

Medical Uses and Dosage.—(See *Senna*). Dose, 1 to 2 fluid drachms.

EXTRACTUM SENNAE ET JALAPÆ FLUIDUM.—FLUID

EXTRACT OF SENNA AND JALAP

SYNONYM: *Fluid extract of antibilious physic.*

Preparation.—Take of senna, in coarse powder, 16 troy ounces; jalap root, in coarse powder, 8 troy ounces; alcohol, a sufficient quantity; carbonate of potassium, 6 drachms; white sugar, 8 troy ounces; diluted alcohol, a sufficient quantity; oil of cloves, 40 minims; oil of anise, 20 minims. Mix the senna and jalap together, and add a sufficient quantity of alcohol to thoroughly moisten them, and let the mixture stand for 24 hours; then transfer it to a percolator, and gradually add alcohol, returning a little of the first that passes till it runs clear. Reserve by itself, of the first percolate, 16 fluid ounces. Then add a sufficient quantity of diluted alcohol to the residuum in the percolator, until the liquid passes but very little impregnated with the properties of the medicine; evaporate this latter solution to 4 fluid ounces, then add the sugar, the carbonate of potassium, the oils of cloves and anise, previously dissolved in a little alcohol, also the reserved tincture, and make 1½ pints of the fluid extract.

Medical Uses and Dosage.—This is a concentrated form of the compound powder of jalap, and may be given with safety in all cases where a purgative is required. Should any resinous matter be deposited, it must be dissolved in alcohol and combined with the extract; the addition of the carbonate of potassium is to enable the resinous matter deposited during evaporation, to be dissolved; also to aid in counteracting the griping property of the medicine. The dose for an adult is 1 fluid drachm, which is about equivalent to 1 drachm of the powder (J. King).

EXTRACTUM SENECTIONIS FLUIDUM.—FLUID.

EXTRACT OF SENECEO.

SYNONYM: *Fluid extract of life-root.*

Preparation.—Take of the recently dried herb *Senecio aureus*, in coarse powder, 16 troy ounces; alcohol, diluted alcohol, each a sufficient quantity. Add a sufficient quantity of the alcohol to the herb to thoroughly moisten it, and allow the mixture to macerate for 24 hours; then transfer it to a percolator, and gradually add alcohol, returning a little of the first that passes, till it runs clear. Reserve, by itself, of the first percolate, 12 fluid ounces. Then pour gradually on the residuum in the percolator, a sufficient quantity of diluted alcohol, until the liquid that passes is but slightly impregnated with the properties of the life-root herb; evaporate this latter solution to 4 fluid ounces, and while warm mix in the reserved tincture, and make 1 pint of fluid extract.

Medical Uses and Dosage.—(See *Senecio*). This fluid extract possesses the medicinal virtues of the life-root, and forms a useful agent in *amenorrhœa*, either alone or in combination with the fluid extracts of black cohosh, water-pepper, etc. It may likewise be used advantageously in the other diseases in which the root is found efficient. The dose is from ½ to 1 fluid drachm, 3 or 4 times a day (J. King).

EXTRACTUM SERPENTARIÆ FLUIDUM (U. S. P.)—FLUID

EXTRACT OF SERPENTARIA.

Preparation.—"Serpentaria, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M]. Mix eight hundred cubic centimeters (800 Cc.) [27 fl̄, 25 M] of alcohol with two hundred

cubic centimeters (200 Cc.) [6 fl̄, 366 M.] of water, and, having moistened the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 M.] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the serpentaria is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 M.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Serpentaria*). This is a thin and transparent, deep reddish-brown concentrated tincture, having the bitter taste and characteristic odor of Virginia snake-root. It fully represents the virtues of the drug. This fluid extract forms a useful tonic, which may be used where the root is admissible. The dose is from 15 to 45 minims, 3 or 4 times a day.

EXTRACTUM SPIGELIÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF SPIGELIA.

Preparation.—“Spigelia, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 8 oza., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]. Moisten the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 M.] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the spigelia is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 M.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Spigelia*). This is a deep-brown translucent, concentrated tincture, possessing the taste of the crude drug. In the original process sugar was employed; this was supplanted, in 1870, by 50 per cent of glycerin; at the present time both have been discarded, the preparation having been found to keep well without them. This forms a fluid extract which may be employed in all cases where pink-root is indicated. The dose for an adult is from 2 to 4 fluid drachms; for a child 1 or 2 years of age, from 10 to 30 minims.

EXTRACTUM SPIGELIÆ FLUIDUM COMPOSITUM.—COMPOUND FLUID EXTRACT OF SPIGELIA.

SYNONYM: *Fluid extract of entozoic powder.*

Preparation.—Take of pink-root, swamp milkweed, mandrake, bitter-root, each, in fine powder, 2½ troy ounces; balmony, in moderately fine powder, 5 troy ounces; alcohol, diluted alcohol, each, a sufficient quantity. Add a sufficient quantity of the alcohol to the powders to thoroughly moisten them, and allow the mixture to macerate for 24 hours; then transfer it to a percolator, and gradually add alcohol until 12 fluid ounces have passed, which set aside. Then gradually add diluted alcohol to the residuum in the percolator, until it is exhausted; evaporate this in a water-bath, to 4 fluid ounces, and, while warm mix in the reserved tincture, and make 1 pint of fluid extract.

Medical Uses and Dosage.—This fluid extract may be used instead of the compound powder of spigelia, in doses of from 5 to 8 drops for a child a year old, or from 10 to 20 drops for an adult, repeating the dose every hour until it acts

freely upon the bowels, after which administer the dose 3 times a day, for several days in succession. A very pleasant preparation for worms may be made by adding 1 part of this fluid extract to 12 parts of simple syrup, of which the dose for a child a year old is a teaspoonful, and for an adult a tablespoonful, to be repeated in the same manner as named in the preceding doses. This will answer especially for those children who can not take the entozoic powder (J. King).

EXTRACTUM SPIGELIÆ ET SENNÆ FLUIDUM.—FLUID EXTRACT OF SPIGELIA AND SENNA.

Preparation.—Take of coarsely-powdered pink-root, 16 ounces (av.); senna, in coarse powder, 8 ounces (av.); white sugar, 24 ounces (av.); carbonate of potassium, 1 ounce (av.); oil of caraway, oil of anise, each, $\frac{1}{2}$ drachm; diluted alcohol, a sufficient quantity. Moisten the pink-root and senna with diluted alcohol, and macerate for 48 hours. Then introduce them into a percolator, and gradually add diluted alcohol until 5 pints have passed. Evaporate this in a water-bath to 20 fluid ounces, and add the carbonate of potassium, which prevents any resinous substance from being precipitated, and also modifies the griping action of the senna. Triturate the oils with a portion of the sugar, then with the whole of it, add this to the evaporated liquid, and dissolve the sugar by a gentle heat. The whole should measure 2 pints (W. Procter, Jr.).

This fluid extract may also be prepared by mixing together fluid extract of pink-root, 5 fluid ounces; fluid extract of senna, 3 fluid ounces, dissolving in them carbonate of potassium, 2 drachms, and oils of caraway and anise, each, 10 minims (W. Procter, Jr., *Proc. Amer. Pharm. Assoc.*, 1859, p. 276).

Medical Uses and Dosage.—This fluid extract, which is an elegant preparation, is quite a pleasant medicine, possessing both cathartic and anthelmintic properties. An adult may take half a fluid ounce or an ordinary tablespoonful for a dose; and a child 2 to 4 years old, 1 fluid drachm or a teaspoonful.

EXTRACTUM STERCOLIÆ FLUIDUM (N. F.)—FLUID EXTRACT OF STERCOLIA.

SYNONYM: *Fluid extract of kola (cola).*

Preparation.—*Formulary number, 175:* "From the seeds of *Sterculia acuminata*, B. Brown (*Kola*; *Kola*). *Process B* (see F. 135). No. 20 powder. *Menstruum I:* Alcohol, two hundred and fifty cubic centimeters (250 Cc.) [8 fl $\bar{3}$, 218 M]; water, six hundred and eighty-five cubic centimeters (685 Cc.) [23 fl $\bar{3}$, 78 M]; glycerin, sixty-five cubic centimeters (65 Cc.) [2 fl $\bar{3}$, 95 M]. *Menstruum II:* Alcohol, 1 volume; water, 3 volumes"—(*Nat. Form.*).

Medical Uses and Dosage.—(See *Kola*). This fluid extract does not mix well with water. The dose is from 10 to 30 minims.

EXTRACTUM STILLINGIÆ.—EXTRACT OF STILLINGIA.

SYNONYM: *Extract of queen's-root.*

Preparation.—Exhaust the recent root of stillingia, cut into small pieces, with alcohol, water, each, a sufficient quantity, proceeding in the manner explained for the preparation of Alcoholic Extracts, on page 758.

Medical Uses and Dosage.—(See *Stillingia*). In large doses the extract of stillingia is emetic and cathartic, for which actions it is but little employed in medicine, on account of the nausea, prostration, and burning sensation at the stomach caused by it. In small doses it is a valuable alterative, peculiar to American practice, and may be efficiently used in all diseases requiring alterative remedies. It is usually given in combination with other alteratives, the virtues of which it appears to increase. The compound syrup of stillingia is now more generally used in practice, but this extract will be found useful in cases where pills are preferred to fluid preparations. The dose is 1, 2, or 3 grains, 3 times a day.

EXTRACTUM STILLINGIÆ FLUIDUM (U. S. P.)—FLUID EXTRACT OF STILLINGIA.

Preparation.—"Stillingia, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the stillingia is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Stillingia*). A dark reddish-brown liquid, with a bitter and pungent taste. It is apt to gelatinize with age. Employed chiefly in *scrofula*, *sypilis*, and *skin affections*. Dose, 10 to 45 minims.

Related Preparation.—The following is the old formula for *Fluid extract of queen's-root* of this Dispensatory: BRONCHIAL ELIXIR.—Take of the recently gathered root of stillingia, cut into small pieces, 16 troy ounces; white sugar, 8 troy ounces; oil of caraway, 1 fluid drachm; diluted alcohol, a sufficient quantity. Moisten the root with diluted alcohol, and let the mixture stand for 24 hours; then transfer it to a percolator, and continue the percolation with diluted alcohol. Reserve the first 12 fluid ounces. Then pour diluted alcohol on the residuum in the percolator, until the liquid that comes through is but slightly impregnated with the properties of the stillingia; add the sugar, and evaporate by a moderate heat to 1 fluid ounce, then mix in the reserved tincture and the oil of caraway, and make 1 pint of fluid extract. This fluid extract possesses all the active properties of the queen's root, in a concentrated form, 1 fluid drachm being equal to 1 drachm of the root. On account of its great activity it is never used in *scrofula*, *sypilis*, etc., in which the more agreeable and sufficiently active and efficient compound syrup of stillingia is preferred. It has been, however, found very efficient in *bronchitis*, *laryngitis*, and various *pulmonary affections*. The dose is from 2 to 5 or 10 drops, to be placed upon the tongue, and allowed to pass very slowly into the stomach.

EXTRACTUM STILLINGIÆ FLUIDUM COMPOSITUM (N. F.) COMPOUND FLUID EXTRACT OF STILLINGIA.

Preparation.—*Formulary number, 176:* "Stillingia, two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.]; corydalis (root), two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.]; iris, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; sambucus, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; chimaphila, one hundred and twenty-five grammes (125 Gm.) [4 ozs. av., 179 grs.]; coriander, sixty-five grammes (65 Gm.) [2 ozs. av., 128 grs.]; xanthoxylum berries, sixty grammes (60 Gm.) [2 ozs. av., 51 grs.]. Reduce the drugs to a moderately coarse (No. 40) powder, and prepare a fluid extract in the usual manner by the process and menstrua below mentioned: *Process B* (see F. 135). *Menstruum I:* Alcohol, five hundred cubic centimeters (500 Cc.) [16 fl̄, 435 m̄]; glycerin, two hundred and fifty cubic centimeters (250 Cc.) [3 fl̄, 218 m̄]; water, two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄]. *Menstruum II:* Diluted alcohol"—(Nat. Form.).

Medical Uses and Dosage.—Chiefly employed as an alterative in *scrofula*, *sypilis*, *rheumatism*, and allied disorders. Dose, 10 to 60 minims.

EXTRACTUM STRAMONII SEMINIS (U. S. P.)—EXTRACT OF STRAMONIUM SEED.

SYNONYMS: *Extractum stramonii* (Pharm., 1880), *Extract of stramonium*.

Preparation.—"Stramonium seed, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity.

Moisten the powder with three hundred cubic centimeters (800 Cc.) [10 fl̄, 69 m̄] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol until three thousand cubic centimeters (3000 Cc.) [101 fl̄, 212 m̄] of tincture are obtained, or the stramonium seed is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 m̄]; mix this with the reserved portion, and, by means of a water-bath, evaporate, at or below the before-mentioned temperature, to a pilular consistence"—(U. S. P.).

Description, Medical Uses, and Dosage.—This preparation is now prepared from the seed instead of the leaves, as in the U. S. P., 1870. Below we give formula for an extract from the leaves, which we have designated *Extractum Stramonii Foliorum*. Extract of stramonium seed is preferable either to an alcoholic or an aqueous extract of the leaves, or their inspissated juice. It is, in large doses, a narcotic poison; in medicinal doses it is anodyne and antispasmodic, and may be administered with benefit in *painful and periodic diseases, nervous excitability or irritability, gastritis, enteritis, peritonitis, dysmenorrhœa, rigidity of the os uteri*, etc. It may also be applied externally in *rheumatic and neuralgic pains*, and to reduce *local inflammations*. The dose is from $\frac{1}{4}$ to $\frac{1}{2}$ grain, 3 times a day.

Related Preparation.—EXTRACTUM STRAMONII FOLIORUM, *Extract of stramonium leaves*. Exhaust recently dried stramonium leaves, in coarse powder, in a percolator with diluted alcohol, a sufficient quantity. (If the diluted alcohol be prepared with a mixture of acetic acid (2 parts), and water (1 part), instead of water alone, it will form a more powerful extract). From the tincture thus made, separate the alcohol, and then carefully evaporate the residue until it is of the required consistence. Be careful not to spoil the extract by too high a temperature while evaporating. When made in large quantity, it should be in vacuo, so that too elevated a temperature may be avoided, and also that the alcohol may be saved (see preparation of Alcoholic Extracts, on page 758).

EXTRACTUM STRAMONII SEMINIS FLUIDUM (U. S. P.) FLUID EXTRACT OF STRAMONIUM SEED.

SYNONYMS: *Extractum stramonii fluidum* (Pharm. 1880), *Fluid extract of stramonium*.

Preparation.—"Stramonium seed, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 m̄] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄] of water, and, having moistened the powder with two hundred cubic centimeters (200 Cc.) [6 fl̄, 366 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the stramonium seed is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Stramonium*). This fluid has a deep-brown color, and, in our opinion, is improved if it be made with official, instead of diluted alcohol. In this case the color will be much lighter and the liquid will be less syrupy. The fixed oil of stramonium has no medicinal value, but nothing is gained by separating it from the drug by preliminary percolation with ether or benzol. Dose, $\frac{1}{4}$ to 2 minims.

EXTRACTUM SUMBUL FLUIDUM.—FLUID**EXTRACT OF SUMBUL.**

Preparation.—Take of sumbul root, in moderately fine powder, 16 troy ounces; alcohol, a sufficient quantity. Moisten the powder with 6 fluid ounces of alcohol. Cork tightly in a wide-mouth bottle, and permit the mixture to stand an hour in a warm situation. Then introduce it into a cylindrical percolator, 8 inches in diameter, previously prepared for percolation, according to directions given on page 756, and press very firmly. Cover the surface of the powder with a circular piece of filtering paper, held in position with a few fragments of glass or marble, and add alcohol until the percolate appears at the exit. Then cork the exit tightly; cover the percolator, and place it in a warm situation. After 24 hours, loosen the cork, and permit the percolate to pass as fast as it will drop, without running in a stream, until 4 fluid ounces are obtained. Again close the exit, macerate 24 hours, and, in a manner like unto the preceding, draw 4 fluid ounces of percolate. Repeat the maceration, and, in like manner, draw a third portion of 4 fluid ounces. Reserve and mix the three percolates; then continue the percolation until 8 fluid ounces are obtained. Evaporate this latter portion until reduced to the measure of 2 fluid ounces, and mix with the reserved 12 fluid ounces. The surface of the powder must be constantly covered with alcohol from the commencement, and until the end of the process of percolation.

Description, Medical Uses, and Dosage.—Fluid extract of sumbul has a dark reddish-brown color, a disagreeable and acrid taste, and possesses the musk-like odor of the root, and as thus prepared, represents very nearly the quality of drug employed, troy ounce to each fluid ounce of the finished extract. Water or glycerin are detrimental, inasmuch as either will prevent the solution of the resin of the root, and can not, in return, dissolve a single therapeutical constituent known to us, that is insoluble in alcohol. When the fluid extract is made with mixtures of alcohol and water, it is very much darker in color than when alcohol only is employed, but is inferior as a therapeutical agent. (For uses, see *Sumbul*). Dose, 10 to 60 minims.

**EXTRACTUM TARAXACI (U. S. P.)—EXTRACT OF
TARAXACUM.**

SYNONYM: *Extract of dandelion.*

Preparation.—“Taraxacum, freshly gathered in autumn, a convenient quantity; water, a sufficient quantity. Slice the taraxacum, and bruise it in a stone mortar, sprinkling water over it from time to time, until it is reduced to a pulp; then express and strain the juice, and evaporate it in a vacuum apparatus, or in a shallow porcelain dish, by means of a water-bath, to a pilular consistence. Keep the extract in a close vessel, and cover its surface with a cloth, which ought to be moistened occasionally with a little ether or chloroform”—(*U. S. P.*).

Description, Medical Uses, and Dosage.—Dandelion root, for the above purpose, should be collected in September, October, or November. The juice procured by the above method should be evaporated in shallow vessels, by means of steam heat; but the best extract is obtained by evaporation in vacuo. In the process of the *British Pharmacopœia*, the clear liquid obtained by expressing the crushed fresh root is directed to be heated to 100° C. (212° F.), and maintained at that point for 10 minutes. This is a wise provision, as the albumen contained in the juice is thereby coagulated, and may subsequently be removed by straining. In the evaporation of this extract, too much heat or too long an exposure to the air will spoil it. When the extract is good, it is brownish, not blackish, bitter and aromatic, and not sweet. A blackish-sweet extract is more or less impaired. The extract should be renewed annually, as it loses its virtues by age and exposure.

Extract of dandelion is tonic, diuretic, and aperient. It is much recommended in *affections of the liver, spleen, and kidneys, in dropsical diseases, etc.* I have made much use of various preparations of dandelion, and the effects are far from being so decided and beneficial as the testimony of writers led me to suppose; we

have several agents vastly superior to it in medicinal efficacy, in the diseases for which it is prescribed. The dose of the extract is from 10 to 60 grains, 3 times a day (J. King).

EXTRACTUM TARAXACI FLUIDUM (U. S. P.)—FLUID EXTRACT OF TARAXACUM.

SYNONYM: *Fluid extract of dandelion.*

Preparation.—"Taraxacum, in No. 30 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; diluted alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of diluted alcohol, and pack it firmly in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding diluted alcohol, until the taraxacum is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 m̄] of the percolate; distill off the alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough diluted alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—This is a red-brown, bitterish-sweet liquid. Fluid extract of dandelion may be administered in all cases when the influence of this drug upon the system is desired. The dose is 1 or 2 fluid drachms, 3 times a day. Some practitioners speak very highly of the therapeutic influence of dandelion; others, myself among the number, do not (J. King).

EXTRACTUM TRILLII FLUIDUM (N. F.)—FLUID EXTRACT OF TRILLIUM.

Preparation.—*Formulary number, 177:* "From the rhizomes of *Trillium erectum*, Linné, and other species of *Trillium* (*Bethroot*). *Process A* (see F. 135). No. 40 powder. *Menstruum:* Alcohol, 8 volumes; water, 2 volumes"—(Nat. Form.).

Medical Uses and Dosage.—(See *Trillium*). Dose, 5 to 30 minims.

EXTRACTUM TRITICI FLUIDUM (U. S. P.)—FLUID EXTRACT OF TRITICUM.

SYNONYM: *Fluid extract of couch-grass.*

Preparation.—"Triticum, finely cut, one thousand grammes (1000 Gm.) [2 lbs. av., 3 oz., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Pack the triticum in a cylindrical percolator, pour boiling water upon it, and allow the percolation to proceed, supplying boiling water as required until the triticum is exhausted. Evaporate the percolate to seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 m̄], and, having added to it two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄] of alcohol, mix well and set it aside for 48 hours. Then filter the liquid and add to the filtrate enough of a mixture of alcohol and water, made in the proportion of 1 volume of alcohol to 3 volumes of water, to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]"—(U. S. P.).

The *German Pharmacopœia* directs that 1 part of couch-grass be digested for 6 hours in 5 parts of boiling water, filtered, and evaporated to an extractive consistence.

Description, Medical Uses, and Dosage.—(See *Triticum*). This forms a sweet, brown extract. It is employed in some demulcent infusion for its influence upon the mucous tissues of the lungs, bowels, and genito-urinary organs. It is less valuable than the decoction. Dose, 2 to 6 fluid drachms.

EXTRACTUM TURNERÆ FLUIDUM.—FLUID EXTRACT OF TURNERA.

SYNONYM: *Fluid extract of damiana.*

Preparation.—Take of the leaves of damiana, in moderately fine portroy ounces; of a menstruum of alcohol, 3 parts, water, 2 parts (by measure sufficient quantity). Moisten the powdered leaves with 6 fluid ounces of menstruum. Cork tightly in a wide-mouth bottle, and permit the mixture to stand an hour in a warm situation. Then introduce it into a cylindrical percolator 3 inches in diameter, previously prepared for percolation, according to the directions given on page 756, and press very firmly. Cover the surface of the powder with a circular piece of filtering paper, held in position with a few fragments of marble, and add fresh menstruum until the percolate appears at the exit; then cork the exit tightly; cover the percolator, and place it in a warm situation for 24 hours, loosen the cork, and permit the percolate to pass as fast as it will without running in a stream, until 4 fluid ounces are obtained. At the exit, macerate 24 hours, and, in a manner like unto the preceding, obtain 4 fluid ounces of percolate. Repeat the maceration, and, in like manner, obtain a third portion of 4 fluid ounces. Reserve and mix the 3 percolates; then evaporate the percolation until 8 fluid ounces are obtained. Evaporate this latter portion until reduced to the measure of 2 fluid ounces, and mix with the reserved 6 fluid ounces. The surface of the powder must be constantly covered with menstruum from the commencement, and until the end of the process of percolation.

Description, Medical Uses, and Dosage.—(See *Damiana*). *Fluid extract of damiana* has a fragrant, herbaceous, balm-like odor and taste, and, when prepared, represents very nearly the quality of the drug employed, excepting that to each fluid ounce of the finished extract.

EXTRACTUM URTICÆ FLUIDUM (N. F.)—FLUID EXTRACT OF URTICA.

Preparation.—*Formulary number*, 179: "From the root of *Urtica* Linné (*Nettle*). *Process A* (see F. 135). No. 40 powder. *Menstruum*: Dilute alcohol"—(*Nat. Form.*).

Medical Uses and Dosage.—(See *Urtica*). This preparation is liable to sedimentation and precipitation, often changing to a gelatinous magma. Use in minims.

EXTRACTUM UVÆ URSI (U. S. P.)—EXTRACT OF UVA URSI.

Preparation.—"Uva ursi, in No. 30 powder, one thousand grains (Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make two hundred cubic centimeters (200 Cc.) [6 fl. oz., 366 M.] of alcohol with five hundred cubic centimeters (500 Cc.) [16 fl. oz., 435 M.] of water, and, having mixed the powder with four hundred cubic centimeters (400 Cc.) [13 fl. oz., 252 M.] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When it begins to drop from the percolator, close the lower orifice, and, having covered the percolator, macerate for 48 hours. Then allow the percolate to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before until the uva ursi is exhausted. Reserve the first percolate, 100 cubic centimeters (900 Cc.) [30 fl. oz., 208 M.] of the percolate; evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to one hundred cubic centimeters (100 Cc.) [3 fl. oz., 183 M.]. Mix this with the reserved portion, and concentrate at or below the before-mentioned temperature, on a water-bath, to a consistency"—(*U. S. P.*).

Medical Uses and Dosage.—(See *Uva Ursi*). This extract may be given in capsules in doses of 10 to 60 grains.

EXTRACTUM UVÆ URSI FLUIDUM (U. S. P.)—FLUID**EXTRACT OF UVA URSI.**

Preparation.—"Uva ursi, in No. 30 powder, one thousand grammes (1000 [2 lbs. av., 3 ozs., 120 grs.]; glycerin, three hundred cubic centimeters (300 [10 fl̄z, 69 m̄]); alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄z, 391 m̄]. Mix the glycerin with two hundred cubic centimeters (200 Cc.) [6 fl̄z, 366 m̄] of alcohol and five hundred cubic centimeters (500 Cc.) [16 fl̄z, 435 m̄] of water, and, having moistened the powder with four hundred cubic centimeters (400 Cc.) [13 fl̄z, 252 m̄] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward a mixture of alcohol and water, made in the proportion of two hundred cubic centimeters (200 Cc.) [6 fl̄z, 366 m̄] of alcohol to five hundred cubic centimeters (500 Cc.) [16 fl̄z, 435 m̄] of water, until the uva ursi is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄z, 208 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough of the mixture of alcohol and water to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄z, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Uva Ursi*). This is a deep-brown fluid of a sweet-bitter and astringent taste. This fluid extract may be used wherever uva ursi is indicated, in doses of a fluid drachm. It has been found very useful in *irritable conditions of the bladder*, associated with 3 to 5 fluid drachms of the fluid extract of lupulin.

EXTRACTUM VALERIANÆ FLUIDUM (U. S. P.)—FLUID**EXTRACT OF VALERIAN.**

Preparation.—"Valerian, in No. 60 powder, one thousand grammes (1000 [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄z, 391 m̄]. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄z, 173 m̄] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄z, 218 m̄] of water, and, having moistened the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄z, 366 m̄] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the valerian is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄z, 356 m̄] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄z, 391 m̄]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Valerian*). This is a deep-brown fluid, representing valerian root in odor and taste. It holds the essence of valerian in a concentrated state, and may be used when desired to counteract the influence of that agent. It may also be combined with various fluid extracts, as of *cimicifuga*, *cypripedium*, *senecio*, etc. The dose is 1 or 2 drachms, 3 times a day, or oftener if required.

EXTRACTUM VANILLÆ FLUIDUM.—FLUID EXTRACT OF VANILLA.

Preparation.—Take of choice vanilla, 1 troy ounce sugar, 14 troy ounces; deodorized alcohol, 4 fluid ounces; diluted alcohol, water, each, a sufficient quantity. Beat the vanilla in short transverse slices, beat it to a pulp with 2 ounces of sugar

and a little alcohol, put the mixture in a small percolator, and pour gradually on, first, the alcohol, and afterward diluted alcohol, till 12 ounces of tincture are obtained. Add 2 ounces of sugar to this tincture, evaporate it at 48.8° C. (120° F.), till reduced to 6 fluid ounces; then add the remainder of the sugar and 5 ounces of water, or as much as is sufficient to make a pint of fluid extract.

Medical Uses and Dosage.—(See *Vanilla*). This extract embodies all the aroma of the beans, and is well adapted for both pharmaceutical and culinary uses. Two fluid ounces added to 2 pints of simple syrup, form an excellent syrup of vanilla, or if a perfectly transparent syrup be desired, 2 ounces of the fluid extract may be triturated with 2 drachms of carbonate of magnesium, to which $\frac{1}{2}$ pint of water may be added gradually; then filter, mix the liquid with another $\frac{1}{2}$ pint of water, and add 2 $\frac{1}{2}$ pounds (troy) of sugar, dissolve with gentle heat, and strain (Wm. Procter, Jr.). In our experience, great care must be exercised in the selection of vanilla. The short beans (vanillons) are not fitted for use other than as tobacco flavors, and seem not to be much, if any, superior to tonka beans for that purpose.

Flavoring Extracts and Essences.—Under the names *Flavoring Extracts and Essences*, mixtures of ethers, solutions of oils, and in some cases tinctures of fruits, are employed in culinary operations and in syrups. These are important as soda water flavors, and chiefly for this purpose do we introduce a few standard extracts of this description, taking the formulæ from "*Elizirs and Flavoring Extracts*," by J. U. Lloyd.

FLAVORING EXTRACT OF CHOCOLATE.—Powdered chocolate, 4 ounces; syrup, water, of each, a sufficient amount. Rub the chocolate in a mortar, with syrup gradually added, until reduced to a cream, then add syrup enough to bring to the measure of 8 fluid ounces, after which add 1 pint of water. Pour the mixture into a pan and bring it to a brisk boil and then allow to cool. This extract is of uncertain quality, owing to the variation in commercial chocolates. It is never transparent, and is likely to deposit considerable sediment. It will ferment in hot weather, and must either be made in small amounts or put into small bottles that are well filled and kept in a cool place. Some persons flavor extract of chocolate with vanilla, but in our experience it is not always acceptable.

FLAVORING EXTRACT OF COFFEE.—Freshly roasted Java coffee, 8 ounces; alcohol and water mixed in the proportion of alcohol 12, water 4, a sufficient amount. Powder the coffee coarsely, moisten with the mixed alcohol and water, and pack in a previously prepared, suitable percolator. Cover the powder with the menstruum (about 20 ounces), and when the percolate appears, close the exit and allow the coffee to macerate 24 hours; then continue the percolation until 1 pint is obtained. The remarks we have made concerning the quality of chocolate will apply also to coffee. The process we commend produces an extract that represents the coffee very accurately, and in our opinion the addition of syrup and glycerin is undesirable.

FLAVORING EXTRACT OF GINGER.—Jamaica ginger, freshly powdered, 2 ounces; alcohol a sufficient amount. Pack the powder in a percolator prepared for percolation. Cover with alcohol (using about 20 fluid ounces), and when the percolate appears, close the exit of the percolator, and macerate for a period of 24 hours. Then percolate slowly until 1 pint of the percolate is obtained. The strength may be increased or diminished to suit the taste of the operator, the quality desired governing in this direction. The diluted alcohol may also be replaced with alcohol.

FLAVORING EXTRACT OF GINGER (Soluble).—Fluid extract of ginger (*U. S. P.*), 4 fluid ounces; magnesium carbonate, water, alcohol, of each, a sufficient amount. Evaporate the fluid extract to 1 fluid ounce; add enough magnesium carbonate to form a creamy mixture, then water to bring to the measure of 8 fluid ounces, rubbing well together, and filter. To the filtrate add enough alcohol to make a total of 16 fluid ounces. Color, if desirable, with caramel. Some persons wish a hot, peppery taste; this is made by using a few drops of tincture of capsicum. The operator can determine the necessity for this addition, and modify the extract to suit the whim of his patrons.

FLAVORING EXTRACT OF LEMON (Good, from the oil).—Oil of lemon, 1 fluid ounce; alcohol, 15 fluid ounces. Mix them together, and after a few days, filter if a precipitate forms. Then color to suit the taste with a little tincture of curcuma.

FLAVORING EXTRACT OF LEMON.—Grate off the outer rind of 4 lemons. Put this into a wide-mouth bottle and pour upon it a pint of alcohol, and add thereto $\frac{1}{2}$ fluid ounce of fresh oil of lemon. Macerate, with occasional shaking, for 4 days, and filter. Color the filtrate to suit the taste with a sufficient amount of tincture of curcuma.

FLAVORING EXTRACT OF NECTAR.—This is one of the fanciful titles that have been given to a soda water syrup that is quite popular. The following formula produces a mixture that gives general satisfaction: Flavoring extracts, of vanilla, 3 fluid ounces; of lemon, 6 fluid ounces; of orange, 4 fluid ounces; of strawberry, 3 fluid ounces. Mix these together, and, if necessary, filter through a little carbonate of magnesium.

FLAVORING EXTRACT OF ORANGE (Good).—Add 1 fluid ounce of sweet oil of orange to 15 fluid ounces of alcohol, and color the mixture to suit the taste with tincture of curcuma modified with a little cochineal color. The manipulator should bear in mind, in the making of flavoring extract of orange, that the demand is for an extract of a dark-yellow color, whereas, in

making an extract of lemon the demand is for an extract of a much lighter color. The various shades can easily be made with different proportions of curcuma tincture and cochineal.

FLAVORING EXTRACT OF PINEAPPLE.—Extract of pineapple is a favorite with some persons, although most people select one of the preceding flavors. It may be said that the majority prefer lemon, vanilla, and orange, but next, perhaps, to these comes pineapple. Extract of pineapple is not made from the fruit, neither is it made from the oil nor a product of the fruit. It is an association of ether flavors which reminds one of the odor of pineapples. The base of pineapple extract is butyric ether, to which are added other substances to modify its harshness.

FLAVORING EXTRACT OF PINEAPPLE (Strong).—Butyric ether, 2 fluid ounces; diluted alcohol, 14 fluid ounces. Mix them together and flavor to suit the taste with a little tincture of curcuma, and modify with enough cochineal color to overcome the bright yellow of the curcuma.

FLAVORING EXTRACT OF RASPBERRY.—That which we have written concerning artificial flavoring extract of strawberry (see below) may be applied to the flavoring extract of raspberry. While some formulae that we have seen are complex and demand the use of rare ethers, we have not observed that the products more nearly resemble the flavor of fresh raspberries than an extract made of cheaper ingredients. We have not as yet found any mixture that will more than remind us of the rich fragrance of the ripe, red raspberry. Indeed, in the raspberry season the artificial imitations of this fruit are far from being satisfactory, although they may be used when the fruit is out of season. The formula for the extract of strawberry is usually adopted, we believe, as that of extract of raspberry, the difference being that the color is intensified in the raspberry. However, we have found the following process to give satisfaction in a commercial way, and we therefore introduce it as a formula for flavoring extract of raspberry: Fluid extract of orris root, 2 fluid ounces; acetic ether, $\frac{1}{2}$ fluid ounce; oil of cognac, 10 drops; butyric ether, 5 drops; diluted alcohol, 16 fluid ounces. Mix the ingredients, color to a dark red with tincture of cochineal, and after a few days filter, if necessary.

FLAVORING EXTRACT OF ROSE.—Oil of rose, 20 drops; alcohol, 4 fluid ounces; water, 12 fluid ounces; diluted alcohol, 16 fluid ounces. Dissolve the oil of rose in the diluted alcohol, and color with cochineal color to suit the taste.

FLAVORING EXTRACT OF SASSAPARILLA.—Oil of wintergreen, $\frac{1}{2}$ ounce; oil of sassafras, $\frac{1}{2}$ ounce; alcohol, 5 fluid ounces; water, 10 fluid ounces; caramel, a sufficient quantity. Triturate the mixed oils with magnesium carbonate, enough to form a thick cream, then with the mixed alcohol and water, and filter. To the filtrate add enough caramel to color it dark brown. This extract is designed to represent the drug neither in flavor nor in quality, but, upon the contrary, is made up of flavors that have been adopted and affixed to the syrup or beverage sold under the name sassafras, and is foreign altogether to the drug. It is used as a flavor for mineral water beverages and soda syrups, and is a mixture of wintergreen and sassafras, and its connection with sassafras drug is imaginary.

FLAVORING EXTRACT OF STRAWBERRY.—Fluid extract of orris root, $\frac{1}{2}$ fluid ounce; acetic ether, 1 fluid drachm; oil of cognac, 5 drops; alcohol, 4 fluid ounces; diluted alcohol, 4 fluid ounces; water, 20 fluid ounces; cochineal color, a sufficient quantity. Mix the ingredients well together. Color to a bright strawberry-red with the cochineal color, and, after a few days, filter if necessary. Extracts of strawberry, as is well known, are made from mixtures of ethers, and, while the flavor is pleasant, and often reminds one of strawberry fruit, still we can not say that the artificial flavors with which we are acquainted compare with the odor of the fresh fruit. They will answer for making syrups when the fruit is out of season, or when a true juice of the fruit can not be obtained, but we must say that we do not commend these artificial extracts as being representatives of the fruit itself. The formulae that we present are such as will produce good trade extracts.

FLAVORING EXTRACT OF WINTERGREEN.—Oil of wintergreen, 1 fluid ounce; alcohol, 15 fluid ounces. Mix them together. This extract may be made of fresh berries, but not of the flavor strength produced by the foregoing formula. There is, perhaps, a freshness in the extract that is made of the berries that is wanting in the solution of the oil; but few persons, however, can procure fresh wintergreen berries. In selecting oil of wintergreen, it is to be borne in mind that the commercial oil is likely to be either oil of white birch or synthetical oil.

EXTRACTUM VERATRI VIRIDIS FLUIDUM (U. S. P.)—FLUID EXTRACT OF VERATRUM VIRIDE.

SYNONYMS: *Fluid extract of American hellebore, Fluid extract of American veratrum.*

Preparation.—“Veratrum viride, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl $\frac{1}{2}$, 391 M]. Moisten the powder with three hundred cubic centimeters (300 Cc.) [10 fl $\frac{1}{2}$, 69 M] of alcohol, pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the Veratrum viride is exhausted. Reserve the first nine hundred cubic centimeters

(900 Cc.) [30 fl̄, 208 M.] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Veratrum*). This preparation holds the alkaloids and resins of veratrum in solution, and is about 2½ times stronger than tincture of veratrum. Dose, ⅓ to 2 minims.

EXTRACTUM VERBASCI FLUIDUM (N. F.)—FLUID

EXTRACT OF VERBASCUM.

Preparation.—*Formulary number*, 180: "From the leaves and flowers of *Verbascum Thapsus*, Linné (*Mullein*). *Process A* (see F. 135). No. 20 powder. *Menstruum*: Diluted alcohol"—(Nat. Form.).

Medical Uses and Dosage.—(See *Verbascum*). Dose, 10 to 60 minims.

EXTRACTUM VERBENÆ FLUIDUM (N. F.)—FLUID

EXTRACT OF VERBENA.

Preparation.—*Formulary number*, 181: "From the root of *Verbena hastata*, Linné (*Vervain*). *Process A* (see F. 135). No. 40 powder. *Menstruum*: Diluted alcohol"—(Nat. Form.).

Medical Uses and Dosage.—(See *Verbena*). Dose, 10 to 60 minims.

EXTRACTUM VIBURNI.—EXTRACT OF VIBURNUM.

SYNONYMS: *Extract of high cranberry bark, Alcoholic extract of cramp-bark, Viburnine.*

Preparation.—Exhaust coarsely-powdered bark of *Viburnum opulus*, with alcohol, water, of each a sufficient quantity, proceeding in the manner explained for the preparation of Alcoholic Extracts, on page 758.

Medical Uses and Dosage.—(See *Viburnum opulus*). Extract of high cranberry bark is tonic and antispasmodic, and may be used in all cases in which the high cranberry bark is indicated. In *uterine difficulties* it may be advantageously combined with some uterine tonic, as resins of caulophyllum or cimicifuga, oleoresin of senecio, alcoholic extract of aletris, etc. In *bilious and flatulent colic*, and *spasmodic pains of the stomach and bowels*, it will be found very efficient in combination with extract of dioscorea. The dose of it is from 1 to 10 grains, 3 times a day (J. King).

EXTRACTUM VIBURNI OPULI FLUIDUM (U. S. P.)—FLUID

EXTRACT OF VIBURNUM OPULUS.

SYNONYM: *Fluid extract of cramp-bark.*

Preparation.—"Viburnum opulus, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M.]. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 M.] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 M.] of water, and, having moistened the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 M.] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before, until the *Viburnum opulus* is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 M.] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the

reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Viburnum*). This is a reddish-brown fluid, having an astringent taste, and practically no odor. It is official for the first time. Dose, $\frac{1}{2}$ to 1 fluid drachm.

EXTRACTUM VIBURNI PRUNIFOLII FLUIDUM (U. S. P.)—FLUID EXTRACT OF VIBURNUM PRUNIFOLIUM.

SYNONYM: *Fluid extract of black haw bark.*

Preparation.—“*Viburnum prunifolium*, in No. 60 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, water, each, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Mix seven hundred and fifty cubic centimeters (750 Cc.) [25 fl̄, 173 m̄] of alcohol with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄] of water, and, having moistened the powder with three hundred cubic centimeters (300 Cc.) [10 fl̄, 69 m̄] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of alcohol and water as before until the *Viburnum prunifolium* is exhausted. Reserve the first eight hundred and fifty cubic centimeters (850 Cc.) [28 fl̄, 356 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—This agent has a deep reddish-brown color and a bitter, astringent taste. Dose, 10 to 60 minims.

EXTRACTUM XANTHOXYLI FLUIDUM (U. S. P.)—FLUID EXTRACT OF XANTHOXYLUM.

SYNONYM: *Fluid extract of prickly ash.*

Preparation.—“*Xanthoxylum*, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 3 ozs., 120 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]. Moisten the powder with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄, 218 m̄] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol, until the *xanthoxylum* is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 fl̄, 208 m̄] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 m̄]”—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Xanthoxylum*). This is a reddish-brown liquid possessing the acrid pungency of the crude drug. Fluid extract of prickly ash bark is a stimulant, tonic, alterative, and sialogogue, and may be used in all cases where the bark is indicated or desired. The dose is from 10 to 60 minims, 3 times a day (J. King.)

EXTRACTUM ZÆ FLUIDUM (N. F.)—FLUID EXTRACT OF ZEA.

SYNONYMS: *Extractum stigmatum maydis fluidum*, *Fluid extract of corn silk.*

Preparation.—*Formulary number*, 182: “From the stigmata of *Zea Mays*, Linné (*Indian corn*). *Process A* (see F. 135). No. 40 powder. *Menstruum*: Diluted alcohol”—(*Nat. Form.*).

Medical Uses and Dosage.—(See *Zea*). Dose, $\frac{1}{2}$ to 2 fluid drachms.

**EXTRACTUM ZINGIBERIS FLUIDUM (U. S. P.)—FLUID
EXTRACT OF GINGER.**

Preparation.—"Ginger, in No. 40 powder, one thousand grammes (1000 Gm.) [2 lbs. av., 8 ozs., 120 grs.]; alcohol, a sufficient quantity to make one thousand cubic centimeters (1000 Cc.) [33 flz, 391 M]. Moisten the powder with two hundred and fifty cubic centimeters (250 Cc.) [8 flz, 218 M] of alcohol, and pack it firmly in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding alcohol until the ginger is exhausted. Reserve the first nine hundred cubic centimeters (900 Cc.) [30 flz, 208 M] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough alcohol to make the fluid extract measure one thousand cubic centimeters (1000 Cc.) [33 flz, 391 M]"—(U. S. P.).

Description, Medical Uses, and Dosage.—(See *Zingiber*). This is a transparent, brownish-red fluid, exhibiting strongly the sensible properties of ginger. Its strength is five-fold that of the tincture. Dose, from 1 to 20 minims.

FABIANA.—FABIANA.

The leaves and branches of *Fabiana imbricata*, Ruiz and Pavon.

Nat. Ord.—Solanaceæ.

COMMON NAME: *Pichi*.

Botanical Source.—*Fabiana* is a tree-like shrub which grows from 15 to 20 feet high, and has short, thick, bluish-green leaves, which are densely imbricated on the branches. The flowers are single, terminal, white or purplish, and tubular, with the corolla much longer than the calyx. The fruit is a 2-celled, 2-valved capsule, enclosing sub-globular, angular seeds.

Fig. 114.

Fabiana imbricata.

History.—This tree-like shrub grows on the dry, sandy hill-tops of Chili. Though belonging to the solanaceous family, it has, when not in bloom, the general appearance of a conifer. The tender portions of the plant are covered with a peculiar, greenish-gray resin, unaffected by water, and affording protection to the plant by preventing the too rapid evaporation of its moisture. The whole plant has a bluish-green aspect. Its Chilean name is *Pichi*. The drug imparts its virtues to alcohol, the tincture yielding a heavy precipitate when added to water. *Pichi* was introduced into American commerce by Parke, Davis & Co., of Detroit, Mich.

Description.—The larger branches abound in resin, and are covered with ash-colored bark, finely beset with minute longitudinal, elevated, and minute protruding glands, exhibiting when magnified, a lustrous, resinous appearance. The younger branches or branchlets, are densely covered with the imbricated leaflets, which are scale-like, long, broad-ovate, sessile, entire, glaucous, and of a blue-green hue. The wood is yellow.

Chemical Composition.—The results of chemical analyses of this drug are somewhat at variance with each other. Dr. Rusby, who studied the plant at the place of its growth, believed the bitterness of the drug to be due to an alkaloid contained in its abundant resin. A. B. Lyons succeeded in isolating from an ethereal solution of the drug a small amount (less than 0.1 per cent), of a substance whose acid solution was bitter and gave the usual reactions for alkaloids. The supposed alkaloid was provisionally named *fabianine*. Besides, Mr. Lyons

found a neutral, crystallizable, tasteless principle, insoluble in water but soluble in ether; furthermore a fluorescent body closely resembling the glucosid *æsculin*, the characteristic constituent of horse-chestnut; also a volatile oil and a bitter resin in great quantity, soluble in alkalies from which solution it was precipitated by acids; it is not fluorescent, is soluble in ether and chloroform, and sparingly soluble in water and petroleum ether (*Amer. Jour. Pharm.*, 1886, p. 65). The ether-soluble crystalline compound alluded to was analyzed by Prof. Trimble and Mr. Schroeter, and its formula ascertained to be $(C_{12}H_{11}O)_2$. H. C. Loudenbeck (*Amer. Jour. Pharm.*, 1891, p. 434), made a complete analysis of the drug, and obtained the fluorescent principle in crystalline form. It had a bitter taste and yielded an intense blue fluorescence with ammonia water, and a rose-red fluorescence in acid solution. The author doubts the existence of an alkaloid in this drug.

Action, Medical Uses, and Dosage.—Pichi has not been extensively employed by Eclectic practitioners. It is reputed a diuretic, tonic, and hepatic stimulant. It favorably influences digestion, and the hepatic benefit derived from it is believed by many to be the indirect result of its effects upon stomach digestion. *Dyspepsia* and *jaundice* have been treated with it. As a diuretic, it acts similarly to the terebinthines and balsams, and like them, is of no value in *structural renal disease*, but of benefit only in functional disorders, and particularly those of a catarrhal type. It has been successfully employed in *cystic catarrh*, both acute and chronic, and is said to be a popular remedy in Chili, for both *hepatic* and *urinary calculi*. *Gonorrhœa*, and *prostatitis* accompanying or following that complaint, are said to be benefited by it. Notwithstanding its irritant character (in large doses), and the view held that it is contraindicated in structural kidney disease, benefit has been claimed from its use as an antihemorrhagic in *albuminuria* when bleeding is associated with the latter disorder. An infusion (3i to water Oij), is given in wineglassful doses every 4 hours; dose of the fluid extract, $\frac{1}{2}$ to 1 fluid drachm every 4 hours, in capsules or flavored emulsion. It precipitates in water unless the latter be alkalized. In doses of from 5 to 20 drops Prof. Webster speaks well of the fluid extract to relieve *urinary irritation*, *dysuria*, *vesical tenesmus*, and *cystitis*. It is also recommended in *nocturnal urinal incontinence*, *renal congestion* (when no organic changes exist), and in alkalized solution in the *uric acid diathesis*.

Specific Indications and Uses.—Cystic irritation, dysuria, and vesical tenesmus, all with catarrhal discharge; vesical pain with frequent urination.

FARINA TRITICI.—WHEATEN FLOUR.

The sifted flour of the grain of *Triticum sativum*, Lamarck (*Triticum vulgare*, Villars).

Nat. Ord.—Graminacæ.

COMMON NAMES: *Common flour*, *Wheat flour*.

ILLUSTRATION (of plant): Bentley and Trimen, *Med. Plants*, 294.

Botanical Source.—This plant, the common winter wheat, described as *Triticum sativum*, var. *hybernum*, has a fibrous root, and a round, smooth, straight stem, 3 to 4 feet or more in height, the internodes being somewhat inflated. The leaves are lance-linear, veined, roughish above, with truncate and bristly stipules. The flowers are borne on a 4-cornered, imbricated, terminal spike, 2 or 3 inches in length, with a tough rachis. The spikelets are crowded, broad-ovate, about 4-flowered; the glumes ventricose, ovate, truncate, mucronate, compressed below the apex, round and convex at the back, with a prominent nervure. The paleæ of the upper florets are somewhat bearded. The grains are loose (W.—L.—Wi.).

History.—Several species of *Triticum* are cultivated in different countries, among which may be named the *Triticum sativum* (*Triticum vulgare*), the species most generally raised in this country and Europe. It has two varieties, *Triticum æstivum*, or spring wheat, and *Triticum hybernum*, or winter wheat. Linnæus considered these as distinct species, but botanists of the present day generally refer them to one common stock. Barley and oats have the perianth attached to the grain, which is not the case with wheat. Wheat is supposed to be a native of Central Asia, in the country of the Baschkirs. The medicinal part is the seeds,

deprived of their husk, and ground to a fine flour. Wheat is subject to ravages from several parasitical fungi, viz.: (1) *Bunt, smut-balls, or pepper-brand*, produced by *Uredo Caries*, and giving a disgusting odor to the flour. This fungous plant is also called *Tilletia Caries*, and infests corn grains and other grasses. (2) *Smut, dust-brand, or burnt-ear*, produced by *Ustilago segetum* (*Uredo segetum*, *Ustilago carbo*). (3) *Rust, red-rag, red-robin, or red-gum*, caused by the young state of *Puccinia graminis*. (4) *Mildew*, produced by the more advanced growth of *P. graminis*. (5) *Ergot*, caused by the *Claviceps purpurea*, and which is as powerful in its action on the uterus as ergot of rye. Two diseases of wheat are produced by parasitical animalcules, viz.: (1) *Ear-cockle, purples, or pepper corn*, caused by a microscopic, eel-shaped, animalcule, called *Vibrio tritici*, or *Anguillula tritici*. (2) *Wheat midge*, an abortion of the grains caused by a minute, 2-winged fly called *Cecidomyia tritici* (P.).

Description and Chemical Composition.—Flour is the finely sifted, amylaceous constituent of the wheat; the broken, integumentary structures constitute bran. Good wheat flour is very white, has a faint, peculiar odor, and is nearly tasteless. One hundred parts of air-dry wheat contain, on an average, 13.37 per cent moisture, 12.04 per cent gluten and other nitrogenous matter, 1.91 per cent fatty matter, 69.07 per cent starch, gum, dextrin, and sugar, 1.9 per cent crude fiber, and 1.71 per cent ash. These figures, recorded by J. König (*Nahrungs und Genuss-mittel*, 3d ed., 1893), represent the average of 1358 analyses of wheat from all parts of the globe. The ash consists of silica, and phosphates of potassium, calcium, magnesium, and sodium, these bases also occurring as sulphates and chlorides. According to the same authority, the composition of wheat-bran is subject to great variation, and the average of 166 analyses is as follows: 15.66 per cent moisture, 14.61 per cent nitrogenous matter, 3.9 per cent fat, 53.6 nitrogen-free extractive matter (starch), etc., 6.7 per cent crude fiber, and 4.94 per cent ash. Richardson and Crampton (1886) found *allantoin* $\frac{1}{4}$ per cent, a quickly drying oil, wax, cane sugar, and a sugar possessing strongly dextrogyre properties. The proportion of these constituents in wheat grains varies according to climate, soil, mode of culture, quality of manure, time of cutting, etc. The starch, which constitutes at least one-half of wheat grains is of finer quality, and of greater density than that from most other sources (see *Amylum*). The nitrogenous or protein matter of wheat consists of small amounts of *vegetable albumin* (about 1.6 per cent), and predominant amounts of the proteids of *gluten*, viz.: *Gluten casein* (Liebig's *vegetable fibrin*), insoluble in alcohol, and *gluten fibrin, gliadin* (glutin or vegetable gelatin) and *mucedin*, the latter three being soluble in alcohol of about 80 per cent strength (Ritthausen). The gluten of wheat is usually assumed as the most perfect form of that principle, and is more abundant in wheat than any other grain, rendering wheat flour superior in the manufacture of bread. It is through the presence of gluten that flour can be made into bread. The added quantity of yeast causes vinous fermentation, with evolution of carbonic acid gas, which expands the gluten into vesicles, and gives to the baked bread its spongy character. If wheat flour be kneaded into a paste with a little water, it forms a tenacious, elastic, soft, ductile mass. This is to be washed cautiously, by kneading it under a small stream of water till the water no longer carries off any starch, and runs off colorless; *gluten* remains. It is of a gray color, exceedingly tenacious, ductile, and elastic, has a peculiar smell, and is nearly tasteless. On exposure to the air it slowly dries, forming a hard, brittle, slightly transparent, dark-brown substance, resembling glue, which breaks like glass, with a vitreous fracture, imbibes water, but loses its tenacity and elasticity by boiling. It decomposes rapidly in a moist atmosphere, emitting a very offensive odor. *Gluten casein* in its reactions exhibits some resemblance to the casein of milk. It is insoluble in pure water, soluble in alkaline water, and precipitated from this solution by acids. It is separated from the gluten of the wheat by treatment with successive portions of alcohol of definite strength, in which it is insoluble. *Gluten fibrin, mucedin*, and *gliadin*, the constituents of gluten proper, are soluble in alcohol of 60 to 80 per cent, their separation being effected by their difference in solubility in water. Gliadin or vegetable gelatin is the constituent that imparts to the gluten its cohesive qualities.

As regards the wheat flour of the markets, we prefer flour ground in the stone mill, bolted in the old style, rather than the white starch flour known as patent process flour. A more recent view of the composition of gluten is that adopted

by Osborne as recorded by Dr. H. W. Wiley (*Principles and Practice of Agricultural Analysis*, 1897, Vol. III, p. 436), from which the following is an abstract: "The gluten of wheat is composed of two proteid bodies, gliadin and glutenin. Gliadin contains 17.66 per cent, and glutenin 17.49 per cent of nitrogen. Gliadin forms a sticky mass when mixed with water, and is prevented from passing into solution by the small amount of mineral salts in the flour. It serves to bind together the other ingredients of the flour, thus rendering the dough tough and coherent. Glutenin serves to fix the gliadin, and thus to make it firm and solid. Glutenin alone can not yield gluten in the absence of gliadin, nor gliadin without the help of glutenin. Soluble metallic salts are also necessary to the formation of gluten, and act by preventing the solution of the gliadin in water, during the process of washing out the starch. No fermentation takes place in the formation of gluten from the ingredients named. The gluten which is obtained in an impure state by the process above described, is therefore not to be regarded as existing as such in the wheat kernel or flour made therefrom, but to arise by a union of its elements by the action of water."

The milky liquid produced by washing wheat flour, as above named, contains in solution gum, sugar, and vegetable albumen. *Vegetable albumen* may be obtained by allowing this fluid to deposit its starch, pouring off the supernatant liquor, and heating it to 60° to 71.1° C. (140° to 160° F.); flakes of coagulated albumen are formed. Vegetable albumen is soluble in water, but when coagulated by heat it is insoluble; it is also insoluble in alcohol and ether. When dry it is opaque, white, gray, brown, or black, according to circumstances, and is not adhesive like gum. Solutions of alkalies readily dissolve it. Vegetable albumen possesses nearly all the characters of animal albumen, and is considered identical in composition with it.

Wheat is now much subject to adulteration in this country by the wholesale admixture of white corn flour; the most we have to fear, however, is diseased wheat; but an examination under the microscope will at once detect parasitical growths, or their spores, etc.

Action and Medical Uses.—Wheat is very nutritive when made into bread or cakes and baked. Toasted bread, infused in water, forms an agreeable and lightly nourishing drink for invalids, especially those suffering from *febrile* or *inflammatory attacks*. It may be sweetened with loaf sugar, or a little molasses, and flavored, if desired, with strawberry juice, raspberry juice, lemon juice, etc., or the syrups of these fruits may be added to flavor it. Wheat flour is occasionally used to lessen the *itching* and *burning sensations* produced by *urticaria*, *scalds*, *burns*, *erysipelas*, etc.; rye-flour, however, is considered to act more efficiently. It is to be dusted upon the affected parts. It cools the part, excludes the air, and absorbs any discharges present, forming with them a crust which effectually protects the part underneath. When bread is soaked in milk, boiling hot, it forms the emollient bread and milk poultice; a small quantity of sweet lard or olive oil added improves it; yeast, with or without charcoal, mixed with this, forms an excellent antiseptic poultice; or, if powdered mustard be added, a sinapism is formed. When a bread poultice is applied to inflamed parts, the addition of a solution of borax will frequently facilitate its action. When it is desired to administer very small doses of remedial agents, this may be accomplished by mixing them with the crumb of bread (*mica panis*) in pill form. But nitrate of silver, if used thus, will be converted into a chloride, by the reaction ensuing between it and the salt in the bread. Wheat flour lightly baked, so as to acquire a pale buff tint, forms an excellent food for infants, invalids, and convalescents. It may be boiled with milk or milk and water, and lightly salted or sweetened as desired.

A very useful article of diet for patients, suitable in nearly all *chronic affections* has been recommended by Dr. T. J. Wright, of Cincinnati: The seeds of wheat are to be well cleansed by several washings in cold water, saving only those which sink to the bottom. Cover these with water, allow them to stand for 12 or 15 hours, then pour off the water, add some more, and boil for 2 or 4 hours, or until the spermoderm is cracked, then remove the wheat from the water. When cold it is ready for use. Small quantities only should be prepared at a time, especially in warm weather. This may be eaten with molasses, or sugar, the same as with boiled rice, or it may be boiled in milk or water, and be formed into a gruel, with the addition of a sufficient amount of Indian meal. It is nutrient and laxative.

BRAN (*Furfures Trivici*), in decoction or infusion, is sometimes employed as an emollient foot-bath; it is also taken internally as a demulcent in *catarrhal affections*. Its continued use causes a *relaxed condition of the bowels*. Bran poultices are sometimes used, warm, in *abdominal inflammations, spasms*, etc. Bread made from unsifted flour has been found beneficial in *indigestion and constipation*. The following forms a good bread for patients laboring under *diabetes*. Wash coarse wheat bran thoroughly with water on a sieve until the water passes through clear; dry this in an oven, grind it to a fine powder, and to 7 eggs, 1 pint of milk, $\frac{1}{2}$ pound of butter, and a little ginger, add enough of the bran flour to make a paste; divide into 7 equal parts, and bake in a quick oven, say from 20 to 25 minutes (P.).

Related Species.—*Vicia Faba*, Linné (*Faba vulgaris*, Moench), *Horse bean, Windsor bean*. The seeds of this plant furnish a flour known as **FARINA FABÆ**. The seeds contain 2 parts of sugar, 2 parts of fat, 36 parts of starch, 9 parts of gummy matter, and 24 parts of legumin. The stalks and husks of this bean, when calcined and digested in white wine, are diuretic; the flowers, in aqueous infusion, are reputed efficient in *gravel and gout*; and the flour has long been a domestic remedy in Europe for *diarrhœa*.

Phaseolus vulgaris, Linné; *Kidney bean; Common bean*.—This bean furnishes a flour, **FARINA PHASEOLI**, whose composition does not vary greatly in proportions from that of the foregoing. The legumes are likewise diuretic, and, according to Soltsien (*Archiv. der Pharm.*, 1884, p. 29), yield an alkaloid, *phaseoline*.

Lolium temulentum, Linné (*Lolium arvense*, Withering); *Bearded darnel*.—This plant is of interest chiefly from the fact that its fruit, or caryopsis, is frequently found with wheat or other grains, and is reputed to possess intoxicant and poisonous qualities. Though common in the grain fields of Europe and western Asia, it is not plentiful in this country, where it has been introduced by sowing grain containing its seed. The fruit is about $\frac{1}{4}$ inch long, oblong-ovoid, usually covered with the palea, smooth, with a convex outer and furrowed inner surface, and of a light-brown color. Internally, the seed is whitish, farinaceous, and has a starchy, bitter taste, but no odor. Several attempts have been made to isolate the toxic principle. The ordinary grain constituents are found in the fruit, a large portion of which (30 to 50 per cent) consists of circular, non-striated starch cells, about $\frac{1}{4}$ the size of those of wheat. The toxic principles of the plant, according to Ludwig and Stahl (1864), are an amorphous, bitter, acrid, yellowish glucosid, dissolving in water, ether, and alcohol, and a fixed oil of an acrid character. Others believed the poisonous body to be an acid substance, while still others have ascribed its action to an oily, non-saponifiable body. *Loliin*, an acrid, dirty-white amorphous body, was isolated by Bley, in 1838. P. Antze (*Amer. Jour. Pharm.*, 1891, p. 558) found what he supposed were two alkaloidal bodies, *loline* (volatile) and *temulentine*, which were shown by Hofmeister (1892) to be respectively impure ammonia and a mixture containing some of the narcotic principle discovered by him, to which he applied the name *temuline*. This is an amorphous alkaline body, probably a pyridine derivative, and soluble in water. An amorphous alkaloid and a nitrogenized acid were also detected by the same author. *Temuline* is poisonous (*Amer. Jour. Pharm.*, 1892, p. 611). The symptoms produced by *lolium* are analogous to those of alcoholic intoxication. Horses, sheep, and dogs are poisoned by it, while cows and hogs remain unaffected, and ducks and quail fatten upon it. Headache, dizziness, disordered vision (sometimes yellow), tinnitus aurium, præcordial oppression and anxiety, lingual pæresis, vomiting, diarrhœa, increased renal action, muscular tremors, cold perspiration, and deep narcosis, sometimes proving fatal, are the effects upon man. *Lolium* has been applied as a poultice to arrest pains of a *neuralgic and rheumatic character*, and in *pleurisy*. Liquors were once adulterated with darnel, and some even suspect its use at the present day, to add to the intoxicating qualities of some beverages.

PHALARIS, Canary seed.—The fruit of *Phalaris canariensis*, Linné, of the Mediterranean basin. It is much used as a food for birds, and, mixed with wheat or rye, has been ground into flour for the use of man. Poultices are also made of it. The fruit is small ($\frac{1}{4}$ inch) flattened, elliptic or ovate, covered by a shining yellow-gray palea. The kernel is brownish externally, white internally, inodorous, and feebly bitter. The fruit (*Fructus canariensis*, or *Semen canariensis*) is composed mainly of starch.

FEL BOVIS (U. S. P.).—OX-GALL.

“The fresh bile of *Bos Taurus*, Linné. Class: Mammalia. Order: Ruminantia.”—(U. S. P.).

SYNONYMS: *Fel tauri*, *Fel bovinum*, *Bilis bubula*.

Source and Description.—The bile of the ox, the fluid secretion of the liver, is of variable consistence, being sometimes limpid, but more commonly viscid andropy. It is denser than water, but mixes with this fluid in every proportion. As described by the U. S. P. it is a “brownish-green or dark-green, somewhat viscid liquid, having a peculiar, unpleasant odor, and a disagreeable, bitter taste. Specific gravity 1.018 to 1.028 at 15° C. (59° F.). It is neutral, or has a faintly alkaline

reaction on litmus paper"—(U. S. P.). It is employed in the preparation of purified ox-gall (see *Fel Bovis Purificatum*).

Chemical Composition.—Ox-gall consists of about 90 per cent of water, the rest being composed mainly of two classes of substances peculiar to bile, called "gall acids" and "gall pigments." Besides, there are present fatty matter (palmitin, stearin, olein, soaps), mucus, albuminous and mineral matter, and traces of urea; also the base, cholin, and a crystallizable monatomic alcohol, named *cholesterin*.

Cholesterin ($C_{27}H_{48}O$) forms the chief ingredient of certain biliary calculi, especially those of human beings. It is also a normal constituent of the brain, the blood, of pus, the intestines, and the yolk of eggs. It also occurs in the seed-embryo of many plants, although an analogous body, *phytosterin*, frequently takes its place therein. *Cholesterin* is insoluble in water, soluble in chloroform, ether, and boiling alcohol, crystallizing upon cooling, and fuses at $145^{\circ}C.$ ($293^{\circ}F.$). It does not dissolve in diluted acids, nor does boiling with caustic alkali affect it in the least. When *cholesterin* is dissolved in chloroform and an equal volume of strong sulphuric acid is added, the *cholesterin* solution assumes a bluish-red, or violet-red color. When placed into a porcelain dish, the color changes from blue to green and finally yellow (*Salkowski's Test*).

The coloring matters of bile or *gall pigments* largely reside in the following:

I. *Bilirubin* ($C_{42}H_{58}N_2O_6$) is the chief coloring principle of bile, and is a red body of an acid character, and is found in appreciable quantities in gall stones in the form of a calcium compound. Usually amorphous, it may be obtained in crystals from its chloroformic solution. It is less soluble in alcohol, sparingly so in ether, and insoluble in water. The alkali compounds of *bilirubin* are insoluble in chloroform, a behavior that affords a means of its isolation. The close connection of *bilirubin* with the hæmatin obtainable from blood, has been suggested.

II. *Biliverdin* ($C_{42}H_{58}N_2O_6$), a green pigment of the bile, is formed by oxidation of *bilirubin*, especially in alkaline solution, by mere exposure to the air. *Biliverdin*, as thus obtained, is soluble in alcohol and alkalies, but not in water, chloroform or ether. Acids precipitate it from its alkaline solutions.

III. *Bilifuscin* ($C_{42}H_{58}N_2O_6$, Staedeler) is a brown pigment, soluble in alcohol and nearly insoluble in ether, chloroform, and water. As to other bile pigments, *biliprasin*, *biliumin*, and *bilicyanin* have been abstracted from gall stones.

Gmelin's Test for bile pigments, which is very delicate, and may be applied to the examination of urine for these pigments, is carried out as follows: Render the suspected liquid faintly alkaline in a test tube, and allow a solution of nitric acid, containing a small amount of nitrous acid, to pass below this liquid. A play of colors will then be noticed at the line of demarkation in the following order from above downward: Green, blue, violet, red, and reddish-yellow. (For an explanation of the chemical processes involved in this reaction, see Hammarstin and Mandel, *Text Book of Physiological Chemistry*, 1893, p. 154.)

The *gall acids* are of 2 groups, and exist in bile in the form of sodium salts. These acids are:

I. *Glycocholic acid* ($C_{26}H_{42}NO_6$) which contains nitrogen, but no sulphur, and occurs mostly in the bile of herbivora.

II. *Taurocholic acid* ($C_{26}H_{42}NSO_6$) which, as the formula indicates, contains both nitrogen and sulphur. It is the main constituent of the solids in the bile of man and carnivora, also of oxen, sheep, and goats.

Glycocholic acid (the *cholic acid* of Strecker and Gmelin), when boiled with excess of alkali, is split into nitrogen-free and crystallizable *cholic acid* (Strecker's *cholalic acid*, $C_{26}H_{42}O_6$), and *glycocol* (*glycin*, or *amido acetic acid*, $CH_2[NH_2]COOH$), the interesting compound obtained also by the decomposition of hippuric acid and of gelatin. *Glycocholic acid* forms silky acicular crystals more soluble in hot than in cold water, soluble in alcohol, sparingly soluble in ether. Its solutions have a bitter-sweetish taste. The aqueous solutions of its salts with alkalies are precipitated by solutions of heavy metals, also by the addition of an acid.

Taurocholic acid ($C_{26}H_{42}NSO_6$) (*choleic acid* of Strecker) occurs in silky needles, readily soluble in water and alcohol, but insoluble in ether. When boiled with alkalies it readily splits into *cholic acid* and *taurin* ($C_2H_4[NH_2]SO_3H$), or *amido isæthionic acid*, a crystallizable substance, soluble in hot water. It has a neutral reaction, since it is both a base and an acid, yet it forms salts with alkalies.

The *bile acids* give Pettenkofer's reaction, which takes place with both the glycocholic and the taurocholic acids, owing to their common constituent, *cholic acid*; yet a variety of cholic acids are known, one of these having received the name *fellic acid*. Pettenkofer's reaction is executed, according to directions of the U. S. P., as follows: "A mixture of 2 drops of ox-gall and 10 Cc. of water, when treated, first, with a drop of a freshly prepared solution of 1 part of sugar in 4 parts of water, and afterward with sulphuric acid, cautiously added, until the precipitate first formed is redissolved, gradually acquires a brownish-red color, changing, successively, to carmine, purple, and violet"—(U. S. P.).

FEL BOVIS PURIFICATUM (U. S. P.), *Purified ox-gall, Purified ox-bile, Fel tauri depuratum*. *Preparation*.—"Take fresh ox-gall, three hundred cubic centimeters (300 Cc.) [10 fl \bar{z} , 70 M \bar{J}]; alcohol, one hundred cubic centimeters (100 Cc.) [3 fl \bar{z} , 183 M \bar{J}]. Evaporate the ox-gall, in a tared porcelain capsule, on a water-bath, to about one hundred grammes (100 Gm.) [3 oz. av., 231 grs.], then add to it the alcohol, mix the whole thoroughly, and set it aside, well covered, for 3 or 4 days. Then decant the clear solution, filter the remainder, and, having mixed the liquids and distilled off the alcohol, evaporate the remainder to a pitular consistence"—(U. S. P.).

Description.—Purified ox-gall is officially described as a "yellowish-green, soft solid, having a peculiar odor, and a partly sweet and partly bitter taste. Very soluble in water and in alcohol. A solution of 1 part of purified ox-gall in about 100 parts of water behaves towards sugar and sulphuric acid in the same manner as the solution mentioned under ox-gall (see *Fel Bovis*). An aqueous solution of purified ox-gall should be clear, and should remain transparent upon the addition of an equal volume of alcohol (evidence of proper purification)"—(U. S. P.).

Action, Medical Uses, and Dosage.—Hepatic, aperient, and tonic. The chief use of this product is for *constipation*, depending upon intestinal atony. Used in *intermittents, dyspepsia, torpor of the liver, jaundice, colic, diarrhoea, dysentery*, etc., when these depend upon a faulty secretion of bile. Five to 8 grains of inspissated gall neutralize the constipating and narcotic effects of 1 grain of opium, without injuring the sedative influence. Dose, from 1 to 10 grains.

A mixture of inspissated ox-bile, 3; extract of conium, 1; soda-soap, 2; olive oil, 8; has been highly extolled as a local application to effect the resolution of *hypertrophied organs*. Bonorden found applications of bile to the eye by instillation, or by means of a hair pencil, 5 or 6 times a day, very beneficial in kindred conditions of the eye, as *pannus, corneal opacity, and staphyloma* (*Med. Times and Gaz.*, 1858, p. 353).

FERRI ACETAS.—FERRIC ACETATE.

FORMULA: $\text{Fe}_2(\text{C}_2\text{H}_3\text{O}_2)_4$. MOLECULAR WEIGHT: 464.96.

SYNONYM: *Acetate of iron*.

Preparation.—(See *Liquor Ferri Acetatis*).

Description.—This solution has a deep-red color, and an acid and strongly chalybeate taste. The salt can not be obtained in dry state, and the solution is liable to decomposition. It is incompatible with alkalies and their carbonates, the strong acids, and vegetable astringent infusions.

Action, Medical Uses, and Dosage.—Tonic and astringent, and possesses the general medical properties of the preparations of iron. A diluted solution of it, with a few drops of creosote, will be found a valuable injection in *leucorrhoea*. Dose, 5 to 20 drops, in water (see *Tinctura Ferri Acetatis*).

Specific Indications and Uses.—(See *Tinctura Ferri Acetatis*).

FERRI ARSENAS.—IRON ARSENATE.

FORMULA: Fe_2AsO_4 . MOLECULAR WEIGHT: 445.18. (As regarded by some, it is FERROSO-FERRIC ARSENATE, $3\text{Fe}(\text{FeO})\text{AsO}_4 + 16\text{H}_2\text{O}$; molecular weight, 1086.74).

SYNONYMS: *Ferrum arsenicum, Ferrous arsenate, Arsenias ferrosus*.

Preparation.—Dissolve sodium acetate 3 parts, and dried sodium arsenate 4 parts, in boiling distilled water 32 parts; pour this solution into another hot

solution made by dissolving ferrous sulphate 9 parts, in distilled water 48 parts. Wash the precipitate well and dry it (see Lloyd's *Chemistry of Medicines*). In the preparation of this salt the *British Pharmacopæia* directs sodium arsenate (dried at 148.9°C . [300°F .]) $15\frac{1}{2}$ parts, ferrous sulphate $20\frac{1}{2}$ parts, and sodium bicarbonate $4\frac{1}{2}$ parts. The product is dried on a porous brick at a temperature not higher than 37.7°C . (100°F .), in a warmed air chamber.

Description.—The dense white precipitate thrown down has the composition Fe_2AsO_4 , but even in the process of preparation, this salt, as it dries through the atmospheric oxidation, changes to various shades of green and blue, finally becoming olive or blue-green in color. It is then regarded as *ferroso-ferric arsenate* ($3\text{Fe}[\text{FeO}]\text{AsO}_4 \cdot 16\text{H}_2\text{O}$), and very much resembles blue phosphate of iron, with which it may be confounded. It is an amorphous, tasteless, odorless powder. Water or alcohol will not dissolve it, though its solution may be effected by diluted acids. It reacts with both ferrocyanide and ferricyanide of potassium, with the former yielding a pale-blue precipitate, and with the latter, a denser, deeper blue precipitate. Its hydrochloric acid solution should not be precipitated by barium chloride (absence of sulphates). If a small portion be boiled with a solution of caustic potash in excess, filtered, and treated with nitric acid to exact neutralization, solution of nitrate of silver will give a brick-red precipitate of silver arsenate. A yellow precipitate (arsenic sulphide), is produced by treating a solution of this salt with hydrogen sulphide.

Action, Medical Uses, and Dosage.—The action of this salt is due chiefly to the arsenic, as the proportion of iron is very insignificant. Carmichael applied this agent as a caustic to *cancerous ulcers* in the following form: Take of arsenate of iron 1 part, phosphate of iron 4 parts, spermaceti cerate 12 parts; triturate together. Bielt has used it in *herpetic, scrofulous, and cancerous affections*, in doses of $\frac{1}{16}$ of a grain, once or twice a day, in pill form, thus: Take of arsenate of iron 3 grains, powdered marshmallow $\frac{1}{2}$ drachm, extract of hops 2 drachms, simple syrup, a sufficient quantity; beat well together and divide into 48 pills. Dose of ferrous arsenate, $\frac{1}{16}$ to $\frac{1}{8}$ grain, 3 times a day.

FERRI BROMIDUM.—FERROUS BROMIDE.

FORMULA: FeBr_2 . **MOLECULAR WEIGHT:** 215.40.

SYNONYMS: *Bromide of iron, Ferrum bromatum.*

Preparation and Description.—Bromine combines directly with iron to form bromide of iron, represented by the above formula and molecular weight. When the two elements are placed together, the chemical reaction is violent, with evolution of heat, and large amounts of bromine are lost by evaporation. For this reason, precautions must be taken to control the reaction. Theoretically, 56 parts of iron are sufficient for 160 parts of bromine; yet, in practice, it is advisable to use a larger proportion of the former. The following process is sufficiently practical for the preparation of bromide of iron on a small scale: Into a chemical flask introduce 2 fluid ounces of distilled water and 1 troy ounce of clean, coarse iron turnings, or iron wire, and surround the flask with ice and water; now add $\frac{1}{2}$ ounce (troy) of bromine, and agitate occasionally, until the solution has almost lost its red color; to the solution, when cold, again add a like amount of bromine, and, when the reaction is finished, add another $\frac{1}{2}$ ounce (troy) of bromine, and so continue successively until a total of 2 troy ounces of bromine has been used; after each addition, permit the reaction to cease, and the liquid to cool. Now warm the flask, and, when the solution has acquired a greenish color, filter quickly; wash the excess of iron and the liberated carbon (that is always present in the iron), with a little distilled water, and filter into the former solution. Transfer this solution at once into a clean iron dish, placed upon a sand bath, and quickly evaporate, until a portion, removed upon a glass rod, will solidify upon cooling; then remove the dry salt, immediately, into well-stoppered bottles. When the reaction is completed with the first portion of bromine, the solution of bromide of iron possesses the power of dissolving bromine, and consequently, the following portions of bromine are dissolved and diluted, thus modifying the chemical action. Solution of bromide of iron absorbs oxygen with avidity, and the most

rapid evaporation will not entirely prevent it. Bromide of iron is of a grayish-black color, acquiring a rusty color upon exposure. It is used in aqueous solution preserved with sugar (see *Syrupus Ferri Bromidi*).

Action, Medical Uses, and Dosage.—Bromide of iron is an uncertain and poisonous agent, and if employed at all internally, it should be with the greatest caution. It is highly probable that the iron furnishes but a very minute amount of any therapeutic value it may possess; and the constant tendency to decomposition renders it an undesirable agent. It is stated to have proved efficient in *scrofulous* and *tuberculous diseases*, in *glandular enlargements*, in some *cutaneous affections*, in *muscular hypertrophy*, *erysipelas*, *leucorrhœa*, *spermatorrhœa*, *bronchocele*, *amenorrhœa*, and even in *phthisis*. It is given internally in the form of syrup in doses of $\frac{1}{2}$ to 1 fluid drachm, and the solution also is applied locally, by means of a camel's hair pencil, or a feather, to the external maladies. Its virtues, if any, are undoubtedly due to the bromine present; on this account some other of the bromides that may be safely administered should be employed when a bromide is indicated; and should iron be also indicated, it can be given separately. Bromide of iron is considerably employed in the manufacture of bromide of potassium.

FERRI CARBONAS SACCHARATUS (U. S. P.)—SACCHARATED FERROUS CARBONATE.

FORMULA of Anhydrous Ferrous Carbonate: FeCO_3 . MOLECULAR WEIGHT: 115.73.

SYNONYMS: *Saccharated carbonate of iron*, *Ferri carbonas saccharata*, *Carbonas ferrosus saccharatus*.

Preparation.—"Ferrous sulphate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; sodium bicarbonate, thirty-five grammes (35 Gm.) [1 oz. av., 103 grs.]; sugar, in fine powder, distilled water, each, a sufficient quantity to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Dissolve the ferrous sulphate in two hundred cubic centimeters (200 Cc.) [6 fl. 3, 366 M.] of hot distilled water, and the sodium bicarbonate in five hundred cubic centimeters (500 Cc.) [16 fl. 3, 435 M.] of distilled water at a temperature not exceeding 50°C . (122°F .), and filter the solutions separately. To the solution of sodium bicarbonate contained in a flask having a capacity of about one thousand cubic centimeters (1000 Cc.) [33 fl. 3, 391 M.], add, gradually, the solution of ferrous sulphate, and mix thoroughly by rotating the flask. Fill up the flask with boiling distilled water, cork it loosely, and set the mixture aside. When the precipitate has subsided, draw off the clear, supernatant liquid by means of a siphon, and then fill the flask again with hot distilled water, and shake it. Again draw off the clear liquid, and repeat the washing with hot distilled water in the same manner until the decanted liquid gives not more than a slight cloudiness with barium chloride test-solution. Finally drain the precipitate thoroughly on a muslin strainer, transfer it to a porcelain capsule containing eighty grammes (80 Gm.) [2 oz. av., 360 grs.] of sugar, and mix intimately. Evaporate the mixture to dryness, by means of a water-bath, reduce it to powder, and mix intimately with it, if necessary, enough well-dried sugar to make the final product weigh one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Keep the product in small, well-stoppered bottles"—(U. S. P.).

The reaction involved herein takes place according to the following equation: $\text{FeSO}_4 + 2\text{NaHCO}_3 = \text{FeCO}_3 + \text{Na}_2\text{SO}_4 + \text{CO}_2 + \text{H}_2\text{O}$. The precipitate of ferrous carbonate rapidly absorbs oxygen from the air, turns brown and gradually parts with its carbon dioxide. The sugar added to the moist carbonate is believed to envelop its particles and thus protect them from oxidation. The precautions taken in the preparation of *Vallet's mass* has this point in view, inasmuch as the precipitate of ferrous carbonate is to be washed out with water containing syrup.

Description.—The U. S. P. describes saccharated carbonate of iron as "a greenish-brown powder, gradually becoming oxidized by contact with air, without odor, and having at first a sweetish, afterward a slightly ferruginous, taste. Only partially soluble in water, but completely soluble in hydrochloric acid, with copious evolution of carbonic acid gas, forming a clear, greenish-yellow liquid"—

(U. S. P.). Cold water dissolves the sugar and a small quantity of iron, and if the solution be heated, it becomes yellow and turbid from the separation of hydrated peroxide of iron, with evolution of carbon dioxide.

Tests.—"If 1 Gm. of saccharated ferrous carbonate be dissolved in 5 Cc. of hydrochloric acid, and the solution diluted with water to the measure of 50 Cc., portions of this solution will afford a blue precipitate with both potassium ferrocyanide T.S. and potassium ferricyanide T.S., but should not be affected by barium chloride T.S. (absence of sulphate). If 1.16 (1.1573) Gm. of saccharated ferrous carbonate be dissolved in 10 Cc. of diluted sulphuric acid, and the solution diluted with water to about 100 Cc., it should require about 15 Cc. of decinormal potassium permanganate V.S. to impart a permanent pink tint to the liquid, corresponding to about 15 per cent of ferrous carbonate (each cubic centimeter of the volumetric solution indicating 1 per cent of pure ferrous carbonate)"—(U. S. P.).

Action, Medical Uses, and Dosage.—This is a useful chalybeate tonic, superior to the carbonate of iron, but not equal to Vallet's pills of carbonate of iron, in which the metal is more completely protected from oxidation (see *Pilulæ Ferri Carbonatis*). The dose is from 5 to 20 grains, in pill; it renders the stools greenish-black.

FERRI CHLORIDUM (U. S. P.)—FERRIC CHLORIDE.

FORMULA: $\text{FeCl}_3 + 12\text{H}_2\text{O}$. MOLECULAR WEIGHT: 539.5.

SYNONYMS: *Chloride of iron, Perchloride of iron, Sesquichloride of iron, Ferri perchloridum, Ferrum muriaticum oxydatum, Chloridum vel chloruretum ferricum.*

Preparation.—"Take of Iron, in the form of fine, bright wire, and cut into small pieces, fifteen grammes (15 Gm.) [232 grs.]; hydrochloric acid, nitric acid, distilled water, each, a sufficient quantity. Introduce the iron wire into a flask having a capacity of about two hundred cubic centimeters (200 Cc.) [6 fl. 3, 366 M], pour upon it fifty-four grammes (54 Gm.) [1 oz. av., 396 grs.] of hydrochloric acid, previously diluted with twenty-five cubic centimeters (25 Cc.) [406 M] of distilled water, and let the mixture stand in a moderately warm place until effervescence ceases; then heat it to the boiling point, filter it through paper, and having rinsed the flask and iron wire with a little hot distilled water, pass the rinsings through the filter. To the filtered liquid add twenty-eight grammes (28 Gm.) [432 grs.] of hydrochloric acid, add the mixture slowly and gradually, in a stream, to eight grammes (8 Gm.) [124 grs.] of nitric acid, contained in a capacious porcelain vessel, and warm gently. After effervescence ceases, apply heat, by means of a sand-bath, until the liquid is free from nitrous odor. Then test a few drops of the liquid, diluted with water, with freshly prepared potassium ferricyanide test-solution. Should this reagent produce a blue color, add a little more nitric acid, drop by drop, as long as effervescence is observed, and evaporate off the excess. Then add five grammes (5 Gm.) [77 grs.] of hydrochloric acid, and enough distilled water to make the whole weigh sixty grammes (60 Gm.) [2 oz. av., 51 grs.], and set this aside, covered with glass, until it forms a solid crystalline mass. Lastly, break the salt into pieces, and keep it in a glass-stoppered bottle, protected from light"—(U. S. P.).

This process does not differ materially from Wittstein's, for an account of which see King's *American Dispensatory*, 15th ed., p. 1010. Metallic iron is rapidly acted on and dissolved in the above process, ferrous chloride (FeCl_2), being formed in the first stage. The hydrogen gas set free possesses a disagreeable smell, which is due to admixed hydrocarbons originating from part of the carbon contained in the iron. The second stage of the process consists in the oxidation of the ferrous to ferric chloride in the presence of hydrochloric acid, by the action of the nitric acid. A sufficient amount of hydrochloric acid must be present in the liquid in order to avoid the presence of basic or oxychloride (see *Tests*, below). Another method of preparing solution of ferric chloride consists in dissolving ferric oxide in hydrochloric acid.

Description.—Ferric chloride is officially described as follows: "Orange-yellow, crystalline pieces, odorless, or having a faint odor of hydrochloric acid, and a strongly styptic taste. Very deliquescent in moist air. Freely and completely

soluble in water and alcohol; also in a mixture of 1 part of ether and 3 parts of alcohol. At 35.5° C. (96° F.), the salt melts, forming a reddish-brown liquid. When strongly heated, it decomposes with the loss of water and hydrochloric acid, while the anhydrous salt sublimes, leaving a residue of ferric oxide"—(U. S. P.). Exposed to the light the salt becomes of lighter color, giving off a part of its chlorine and becoming ferrous chloride; the action of air and light must therefore be avoided.

Tests.—"The dilute, aqueous solution of the salt is acid to litmus paper, yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide T.S., and a white one, insoluble in nitric acid, with silver nitrate T.S. If the iron be completely precipitated from a solution of the salt by an excess of ammonia water, the filtrate should be colorless, and should not yield either a white or a dark-colored precipitate with hydrogen sulphide T.S. (absence of zinc or copper); nor should it leave a fixed residue on evaporation and gentle ignition (absence of salts of the fixed alkalies). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a moderately dilute solution of the salt, the crystal should not become colored brown, nor should there be a brownish-black color developed around it (absence of nitric acid). If to a dilute solution of the salt a few drops of freshly prepared potassium ferricyanide T.S., be added, a pure brown color should be produced, without a tinge of green or greenish-blue (absence of ferrous salt). A 1 per cent aqueous solution of the salt, when boiled in a test-tube, should remain clear (absence of oxychloride). If 0.56 (0.5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 Cc.), in 10 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled and mixed with a few drops of starch T.S., it should require 20 Cc. of decinormal sodium hypophosphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 1 per cent of metallic iron)"—(U. S. P.).

Action, Medical Uses, and Dosage.—Perchloride of iron is given in solution (see *Liquor Ferri Chloridi*), and is a powerful styptic. Internally, it has been successfully administered in *epistaxis*, *hemoptysis*, *hematemesis*, *menorrhagia*, *uterine* and other *hemorrhages* of a passive character, and in *hydruria*, *urinal incontinence*, and *catarrh of the bladder*, the dose being from 5 to 10 drops in a sufficient quantity of water, and repeating it 2, 3, or even 4 times a day. It has been used with asserted success in *pharyngeal diphtheria*. It has also been used in surgery, in the treatment of *aneurism* and *varicose veins*; a few drops of the concentrated solution of the perchloride is injected into the arteries or veins, under the influence of which all the blood within a distance of 2 or 3 lines is converted in a few minutes into a solid clot. Its use in aneurism has been abandoned owing to its having produced suppurative infiltration, or fatal embolism. It has not yet been determined what is the real mode of action of this salt on the blood. According to some, it coagulates the whole of the blood and all its elements; according to others, it acts only on the fibrin, and others, again, contend that its action is confined to the albumen. A solution of the salt, as named above, is the best form of preparation, though it decomposes on standing.

Perchloride of iron arrests *arterial* or *venous hemorrhage* resulting either from accident, or as a consequence of *surgical operations*. *Hemorrhage from the bowels* may be checked by an enema composed of from 20 to 25 drops of a concentrated solution of perchloride of iron to 7 ounces of fluid. *Hemorrhage from an abscess* may be checked by injecting a solution composed of 10 drops of the concentrated solution to 7 fluid ounces of water. Twenty drops to 3½ fluid ounces of water has been successfully used as an injection in *chronic gonorrhœa* or *leucorrhœa*, in weak and lymphatic subjects. As a local or external hemostatic, from 3 to 5 parts of perchloride of iron may be dissolved in 100 parts of distilled water; lint may be thoroughly moistened with this, and applied upon the seat of hemorrhage, with more or less pressure. One part of perchloride of iron to 500 parts of distilled water, and the solution sweetened and administered internally in proper doses, checks the most profuse hemorrhages in from 24 to 36 hours, and is also useful in *chronic diarrhœa*; without the sweetening, it is useful as an injection in *uterine*

flooding, cholera, colliquative diarrhœa, etc. Many deaths have been attributed to its use in strong solutions as a means of arresting uterine hemorrhage. Mr. J. T. Lawrence says: "If the solid perchloride of iron be kept in a bottle, a small portion of it after a time deliquesces into a thick brown fluid, which is constantly kept in a state of supersaturation by the undeliquesced portions of the salt. This liquid, applied by means of a spun-glass brush, to a bleeding surface, arrests the bleeding almost instantaneously. This mode of application is particularly valuable in applying the styptic to such cases as *excision of the tonsils*, bleeding from the deeper-seated vessels of the gums, etc." The solution is considered effective in destroying *vascular nævi, erectile tumors*, and the *granulations of ingrown nails*. It has also been applied in *chilblains, scrofulous ulcers, hospital gangrene, sweating feet, and rectal prolapse*. Dense, confluent granulations within the tympanic cavity are removed with a crystal or strong solution of chloride of iron with less pain than with silver nitrate (Foltz).

Jeannel proposed a perchloride of iron for therapeutical purposes, containing 5 molecules of oxide of iron. It is prepared with 100 parts of pure hydrochloric acid of sp. gr. 1.15, and 522 parts of ferric hydroxide containing 75 parts of water. Dissolve cold by trituration in a glass mortar, and filter. It forms a limpid, deep, garnet-red fluid, with an astringent, but not bitter taste. It very strongly coagulates blood and albumen, and the coagulum does not become redissolved, as is the case when the official perchloride is used; it is not painful when applied to wounds; may be readily dried on plates placed in a stove heated to 40° C. (104° F.), yielding blackish-brown, very soluble laminae, which, when powdered, form an excellent local application for modifying wounds affected with *hospital gangrene, abscesses of a bad character, phagedenic chancres*, etc.

Related Salt.—*FERRUM CHLORATUM, Ferrous chloride, Chloridum ferroum, Ferrum muriaicum oxydulatum.* Formula: FeCl_2 . Molecular weight: 126.84. This salt may be easily made by digesting in a porcelain vessel iron turnings (1 part), in hydrochloric acid (4 parts), the latter having been previously diluted with distilled water (2 parts). The mixture is to be warmed, filtered, and carefully evaporated until the bulk is reduced to the measure of that of 3 parts of the acid employed. Add a little hydrochloric acid and allow it to crystallize in a cool situation (Lloyd's Chem. of Med.). Ferrous chloride forms pale-green crystals, and contains 4 molecules of water. In moist air it deliquesces, changing in color by oxidation gradually, from green to yellow. As stated before, the first step in the preparation of ferric chloride consists in the making of ferrous chloride. In Germany a *Liquor Ferri Chloratum* is prepared. Ferrous chloride has been given in doses of from 1 to 5 grains in that country.

FERRI CITRAS (U. S. P.)—FERRIC CITRATE.

FORMULA: $\text{Fe}_2(\text{C}_6\text{H}_5\text{O}_7)_3$, (for anhydrous salt). MOLECULAR WEIGHT: 488.84.

SYNONYMS: *Citrate of iron, Insoluble (?) citrate of iron, Ferrum citricum oxydatum, Citras ferricus.*

Preparation.—"Take of solution of ferric citrate, a convenient quantity. Evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light"—(U. S. P.).

Description and Tests.—"Thin, transparent, garnet-red scales, without odor, and having a slightly ferruginous taste. Slowly but completely soluble in cold water, and readily soluble in hot water, but diminishing in solubility by age. Insoluble in alcohol. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which should not have an alkaline reaction upon litmus paper (absence of citrates or tartrates of the fixed alkalies). The aqueous solution of the salt has an acid reaction, and is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide T.S. it produces a bluish-green color or precipitate, which is increased and rendered dark-blue by the subsequent addition of hydrochloric acid (difference from iron and ammonium citrate). When heated with potassium or sodium hydrate T.S., it affords a brownish-red precipitate, without evolving any vapor of ammonia. If a 10 per cent solution of the salt be deprived of its iron by boiling it with an excess of potassium or sodium hydrate T.S., and the filtrate be slightly acidulated with

acetic acid, a portion of the cooled liquid, mixed with a little calcium chloride T.S., and again heated to boiling, will gradually afford a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for some time, should not deposit a white, crystalline precipitate (absence of tartrate). If 0.56 (0.5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 Cc.) in 15 Cc. of water and 2 Cc. of hydrochloric acid, with the aid of a gentle heat, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require about 16 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 1 per cent of metallic iron)"—(U. S. P.).

Iron and ammonium citrate is often sold under the name of *soluble citrate of iron*.

Action, Medical Uses, and Dosage.—(See *Ferri et Ammonii Citras*). Dose, 2 to 10 grains, in aqueous solution or pill.

FERRUM DIALYSATUM.—DIALYZED IRON.

SYNONYMS: *Liquor ferri dialysatus, Liquor ferri oxychlorati.*

Preparation.—The Paris Pharmaceutical Society (1876) adopted the following process: To 100 grammes ($3\frac{1}{2}$ fluid ounces) of solution of ferric chloride, sp. gr. 1.245, 35 grammes ($1\frac{1}{4}$ fluid ounces) of ammonia water, sp. gr. 0.923 (=20.26 per cent) are slowly added, with constant stirring, and as soon as a clear solution has formed it is introduced into the dialyzer (see *Dialysis* below); the surrounding water, during the process of dialyzation, being frequently changed. When the contents of the dialyzer (as may be determined by testing a small portion from time to time) cease to precipitate a solution of nitrate of silver, and give no acid reaction, the operation is suspended.

Dr. W. H. Pile recommends the addition of solution of carbonate of sodium to the solution of chloride of iron, until a small portion of the resulting precipitate remains undissolved, and then to proceed with the dialysis. In this case, chloride of sodium passes through the septum. We believe the process now in general favor is to add freshly precipitated ferric hydrate to the solution of ferric chloride, until saturation ensues, and then dialyze the resulting liquid. In all cases the results of the operation are similar, and the solution within the dialyzer should, after the completion of the process, be brought to the proper standard by drying a given portion, and then adding distilled water in sufficient quantity to make 100 parts by weight of the solution contain 5 parts of the dry residue.

Description and Chemical Composition.—Dialyzed iron has a deep-red color, and is miscible with distilled water, glycerin, and syrup. Fixed organic acids, alkalis, and salts form with it a clear jelly. It is odorless and almost tasteless, merely imparting a slight rough sensation to the tongue. In composition it is a very basic oxychloride, and, as found in the market, differs considerably in constitution. It is not, as some have supposed, a neutral solution of oxide of iron. Specimens that are neutral to litmus paper, and that fail to show the presence of chlorine upon simply adding nitrate of silver to the solution of iron will, as Prof. Maisch has shown, give distinct precipitates, when a slight excess of ammonia water is previously added to the dialyzed iron, the mixture then filtered and the clear filtrate tested with solution of nitrate of silver. (For exhaustive articles on the subject we refer the reader to *Amer. Jour. Pharm.*, 1877-78).

According to the analyses of Prof. Trimble (*Amer. Jour. Pharm.*, 1878, p. 61), 6 specimens of commercial dialyzed iron varied in composition from $\text{Fe}_2\text{Cl}_4 \cdot 11\text{Fe}_2\text{O}_3$ to $\text{Fe}_2\text{Cl}_4 \cdot 31\text{Fe}_2\text{O}_3$. No specimen contained 5 per cent of solid matter, the highest being 4.831 per cent, the lowest 2.514 per cent. The specific gravity of 5 per cent dialyzed iron, according to Dr. W. H. Pile, is 1.029. Mr. E. B. Shuttleworth (*Canad. Pharm. Jour.*, 1877), states, however, that it is 1.034 if the evaporation of the solution tested has been conducted over an exposed water-bath, and 1.040 when the perfectly dry residue is 5 per cent. If calcined, a residue of 5 per cent indicates a solution of specific gravity 1.046. If the process of dialysis is carried

to excess, the resultant solution is prone to thicken. This is often observed in dialyzed iron where extra care has been taken that the process be carried to the utmost extent (see *Dialysis* below).

Action, Medical Uses, and Dosage.—Dialyzed iron has been presented to the medical profession as a remedy devoid of any styptic, disagreeable taste, producing no heartburn, eructations, constipation, diarrhoea, or gastric disturbance, occasioning no blackening of the teeth, and being a ferric solution in a form closely resembling that of the iron in the blood. It has likewise been recommended as an antidote for poisoning by arsenic, fully as efficient as the hydrated sesquioxide of iron. Its dose is from 20 to 50 drops daily, or from 5 to 12 drops repeated 4 times a day. It may be dropped upon a lump of sugar, or be taken in a little water, wine, or coffee. This preparation has been recommended in all cases in which the administration of iron is indicated, but it has not given general satisfaction among those who have employed it; and from what has been gathered from those who have tested it as an arsenical antidote, it certainly appears to be an uncertain and unreliable remedy. Prof. Depaire, of the University of Brussels (*Jour. de Médecine de Bruxelles*, 1877) considers that this agent should be ranked among the least active of ferruginous preparations. Bouchardat, of Paris, France, says: "Theoretically, dialyzed iron appears to me to be the most untrustworthy of the ferruginous preparations in which the ferric oxide occurs, and for two reasons—the iron called *dialyzed*, does not pass through the dialyzer, it must then be illy adapted for absorption; under the influence of very small quantities of alkali, of alkaline earths, of acids, of divers substances contained in the food, it becomes converted into an insoluble compound." Physicians in Germany frequently prescribe it as follows: Take of dialyzed iron, cinnamon water, each, 15 fluid drachms; glycerin, alcohol, each, 2½ fluid drachms; mix. The dose of this for an adult is a dessertspoonful, repeated 3 or 4 times a day. Each spoonful contains 2.14 grammes (33 troy grains) of dialyzed oxide of iron, or 10 centigrammes (1½ troy grains) of dry oxide of iron.

Dialysis.—The name *dialysis* was applied, by Graham, to the act of separating certain bodies when in solution, by taking advantage of the fact that some substances pass more readily than others through certain gelatinous bodies. Those most diffusible, either crystallize or are closely related to crystalline classes, hence called *crystalloids*. The less diffusible prove to be those incapable of crystallizing, usually prone to assume the gelatinous form, being distinguished as *colloids*. The principle of dialysis has, occasionally, for some years, been applied in practice, as in separating arsenous anhydrid, and other metallic poisons, from liquids containing organic matter; also in the separation of the crystallizable constituents of urine, as urea, etc. A layer of gelatin will serve as a dialyzer, but a septum of animal membrane, such as bladder, or a piece of parchment, is better adapted to the purpose. The dialyzer is generally made by tying a sheet of parchment over a wooden hoop, or over a glass or rubber cylinder, or even over the wide open end of a funnel. The liquid to be dialyzed is then placed inside the vessel thus made, and the whole arrangement is permitted to float upon distilled water. In case the vessel is heavy, it is better to support it in such a manner that the surface of the liquid within the dialyzer will be a little above the surface of the surrounding water. This is necessary to prevent an excessive inflow of water, which, in some cases, renders the liquid very dilute before dialysis has progressed to any great extent.

From 9 to 14 days are generally required to complete the operation, but the process is influenced by the depth of the solution within the dialyzer, the extent of surface exposed, and the quality of the membrane employed, as well as by the attention given to a frequent change of the water in which the dialyzer floats. The most rapid work is accomplished with a constantly changing water below, and a thin stratum of liquid above, the membrane. The process of dialysis came into extensive use as a means of making *dialyzed iron*, but this preparation, in recent years, has largely fallen into disuse.

FERRI ET AMMONII CITRAS (U. S. P.)—IRON AND AMMONIUM CITRATE.

SYNONYMS: *Ammonio-ferric citrate, Ammonio-citrate of iron, Citrate of iron and ammonium, Soluble citrate of iron, Ferrum citricum ammoniatum, Ferro-ammonium citricum, Ferri ammonio-citras.*

Preparation.—"Take of solution of ferric citrate, one hundred cubic centimeters (100 Cc.) [3 fl.℥, 183 M]; ammonia water, forty cubic centimeters (40 Cc.) [1 fl.℥, 169 M]. Mix the solution of ferric citrate with the ammonia water, evaporate the mixture, by means of a water-bath, at a temperature not exceeding 60° C.

(140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light"—(U. S. P.).

As made by the foregoing process, ammonio-ferric citrate has the rather constant composition, $\text{Fe}(\text{C}_6\text{H}_5\text{O}_7)_3\text{NH}_4\text{OH}$ (R. Rother, *Amer. Jour. Pharm.*, 1887, p. 170). The following process is taken from Lloyd's *Chemistry of Medicines*: "Dissolve the ferric oxide from 1 pint of solution of persulphate of iron (tersulphate U. S. P.), by digesting it in a porcelain dish, at a temperature of 82.2° C. (180° F.), with 4 ounces (av.) of citric acid, and 5 fluid ounces of solution of citrate of ammonium. (Solution of citrate of ammonium for this purpose is made by dissolving 8 ounces (av.) of citric acid in an excess of ammonia water, and evaporating the product until it is reduced to the measure of 16 fluid ounces). When solution is complete, evaporate the product to the consistence of syrup, and dry by spreading it on plates of glass and exposing it to the temperature of from 37.7° C. to 50° C. (100° to 120° F.)."

Description and Tests.—Iron and ammonium citrate is officially described as occurring in "thin, transparent, garnet-red scales, without odor, and having a saline, mildly ferruginous taste; deliquescent in moist air. Readily and completely soluble in water, but insoluble in alcohol. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which should not have an alkaline reaction towards litmus paper (absence of citrates or tartrates of the fixed alkalies). The aqueous solution of the salt is neutral to litmus paper. The aqueous solution is not precipitated, but rendered darker in color by ammonia water. With potassium ferrocyanide T.S., the solution does not give a blue color or precipitate, unless it be acidulated with hydrochloric acid (difference from ferric citrate). When heated with potassium or sodium hydrate T.S., it affords a brownish-red precipitate, and vapor of ammonia is evolved. If a 10 per cent solution of the salt be deprived of its iron by boiling it with an excess of potassium or sodium hydrate T.S., and the filtrate slightly acidulated with acetic acid, a portion of the cooled liquid mixed with a little calcium chloride T.S., and again heated to boiling, will gradually deposit a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for some time, should not yield a white crystalline precipitate (absence of tartrate). If 0.56 (0.5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 Cc.) in 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require about 16 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 1 per cent of metallic iron)"—(U. S. P.). Being more soluble than citrate of iron, this salt is the substance usually prescribed and sold under the name *Citrate of iron* or *Soluble citrate of iron*. Should it deliquesce in the air, too much ammonia has been used in its production; if sour and of acid reaction, an excess of citric acid has been employed; and if dusty or finely divided, an excess of oxide of iron is present (Lloyd's *Chem. of Med.*). Ammonia is evolved when the salt is calcined.

Action, Medical Uses, and Dosage.—This salt, as well as citrate of iron, is a pleasant, ferruginous tonic, and may be given to children in ordinary cases of debility, struma, anemia, *tabes mesenterica*, etc. It does not constipate, and is easily assimilated, and is therefore a good iron tonic in *dyspepsia* with gastric irritability and marked anemia. The dose of either is from 4 to 10 grains in pill, or in water flavored with orange-peel, syrup, etc. The citrate is best given in the form of pill. The ammonio-citrate is not adapted for use in pill.

Specific Indications and Uses.—Anemia; skin pale, translucent, membranes pale, respiration accelerated; appetite morbid; patient restless and nervous.

Related Compound.—**FERRI ET ZINCI CITRAS**, *Iron and zinc citrate*. This preparation is but little used. It forms in brownish-green scales, and has a ferruginous and slightly metallic taste. As, in addition to the citrates of iron and zinc, it contains ammonia, it is more properly an "ammonio-citrate of iron and zinc." Used as a tonic in cases where iron is not contraindicated, as, in *anemia*, *chorea*, *epilepsy*, and other diseases of the nervous system. The dose is from 2 to 5 grains, 2 or 3 times a day (H. N. Draper).

FERRI ET AMMONII SULPHAS (U. S. P.)—IRON AND AMMONIUM SULPHATE.

FORMULA: $(\text{NH}_4)_2\text{Fe}(\text{SO}_4)_2 \cdot 24\text{H}_2\text{O}$. MOLECULAR WEIGHT: 962.1.

SYNONYMS: *Ammonio-ferric sulphate, Ammonio-ferric alum, Sulphas ammonice ferricus, Ferri ammonio-sulphas, Ferrum ammonio-sulphuricum, Ferrum sulphuricum oxydatum ammoniatum, Alumen ammoniacale ferricum, Ferrum sulfuricum oxydatum ammoniatum.*

Preparation.—The U. S. P. (1870) presents a formula for the preparation of this salt, in which it is recommended to “heat 2 pints of a solution of tersulphate of iron (see *Liquor Ferri Tersulphatis*) to the boiling point, then add to it $4\frac{1}{2}$ troy ounces of sulphate of ammonium, and when this is dissolved, to set the fluid aside to crystallize, wash the crystals quickly with very cold water, wrap them in bibulous paper, and dry them in the open air.” According to Lloyd’s *Chemistry of Medicines*, it is not necessary to boil the solution; a temperature of 65.5°C . (150°F .) is sufficient.

Description and Tests.—According to Rose, *pure ammonio-ferric alum is white, becoming colored only in aqueous solution, through the formation of a basic iron salt, a change which may be prevented by acidulating the solution with sulphuric acid. As usually met with in commerce, it is of amethyst-like color. “Ferric ammonium sulphate should be kept in well-stoppered bottles”*—(U. S. P.).

The U. S. P. describes it as occurring in “pale violet, octahedral crystals, without odor, and having an acid, styptic taste; efflorescent on exposure to the air. Soluble in 3 parts of water at 15°C . (59°F .), and in 0.8 part of boiling water; insoluble in alcohol. When strongly heated, the crystals fuse, lose their water of crystallization, swell up, and finally leave a pale-brown residue. The aqueous solution of the salt has a slightly acid reaction, and yields with potassium ferrocyanide T.S. a blue precipitate, and with barium chloride T.S. a white precipitate insoluble in hydrochloric acid. With potassium or sodium hydrate T.S. it yields a brownish-red precipitate, and if the mixture be heated, vapor of ammonia is evolved. If all the iron be precipitated from a solution of the salt by treating it with an excess of potassium or sodium hydrate T.S., the resulting filtrate, when neutralized with hydrochloric acid, and then mixed with ammonia water, should not yield a white, gelatinous precipitate (absence of aluminum). If 0.56 (0.5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 Cc.) in 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for $\frac{1}{2}$ hour at a temperature of 40°C . (104°F .), then cooled, and mixed with a few drops of starch T.S., it should require not less than 11.6 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 1 per cent of metallic iron)”—(U. S. P.).

IRON ALUM was brought to the notice of the profession by Dr. Wm. Tyler Smith. Beside the *ammonio-ferric alum* before described, there exist other iron alums, in which the ammonium is replaced by potassium or sodium or other alkali metals. The *potassio-ferric alum* ($\text{Fe}_2[\text{SO}_4]_3 \cdot \text{K}_2\text{SO}_4 \cdot 24\text{H}_2\text{O}$) (which is prepared exactly like ammonio-ferric alum, except that potassium sulphate is employed in the place of ammonium sulphate), has long been used in St. Mary’s Hospital, London, as a more powerful astringent than common alum, and not liable to produce the stimulating effects of other salts of iron. *Ammonio-ferric alum* possesses similar properties.

Action, Medical Uses, and Dosage.—Dr. Wm. Tyler Smith speaks very highly of these iron alums in *leucorrhœa* in doses of from 3 to 10 or 15 grains, in infusion of columbo, or in water, repeated 3 times a day. They have also been found useful in *choleraic diarrhœa*, *dysentery*, and other disorders in which tonic and astringency are required. They are more effective than the perchloride of iron, being at the same time less stimulating, more easily assimilated, and rarely causing any nausea or headache. Occasionally they induce slight constipation, which may be obviated by an occasional laxative, as magnesium sulphate, compound licorice powder, etc.

Related Preparation.—FERROSO-ALUMINIC SULPHATE. *Sulphate of aluminum and iron* ($\text{Al}, \text{Fe}(\text{SO}_4)_2, 24\text{H}_2\text{O}$). This substance may be formed by dissolving in an excess of sulphuric acid, recently precipitated ferrous carbonate and recently precipitated alumina in such proportions as are demanded by the above formula. By evaporating the solution thus formed, if kept in a warm situation, it deposits crystalline tufts of the ferroso-aluminic sulphate. It was introduced by Sir James Murray as an astringent, styptic, and anthelmintic. For its astringent effects it has been employed in *bowel disorders, night-sweats, and leucorrhœa*. The dose is from 5 to 10 grains in water. Locally used in *relaxed palate and uvula, sluggish ulcers, and hemorrhages*.

FERRI ET AMMONII TARTRAS (U. S. P.)—IRON AND AMMONIUM TARTRATE

SYNONYMS: *Ammonio-ferric tartrate, Ammonio-tartrate of iron, Ferri ammonio-tartras, Ferrum tartaricum ammoniatum.*

Preparation.—The following official process is practically based on that elaborated by Prof. Procter in 1841 (*Amer. Jour. Pharm.*, 1841): "Solution of ferric sulphate, one hundred cubic centimeters (100 Cc.) [3 fl̄z, 183 M]; tartaric acid, twenty-nine grammes (29 Gm.) [448 grs.]; distilled water, two hundred cubic centimeters (200 Cc.) [6 fl̄z, 366 M]; ammonia water, water, each, a sufficient quantity. To one hundred and ten cubic centimeters (110 Cc.) [3 fl̄z, 345 M] of ammonia water, previously diluted with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄z, 218 M] of cold water, add, with constant stirring, the solution of ferric sulphate, previously diluted with thirteen hundred cubic centimeters (1300 Cc.) [43 fl̄z, 460 M] of cold water. When the precipitate has subsided, draw off the clear, supernatant liquid by means of a siphon, then mix the precipitate intimately with about fifteen hundred cubic centimeters (1500 Cc.) [50 fl̄z, 346 M] of cold water, again draw off the clear liquid, and repeat the washing with water in the same manner until the decanted liquid gives not more than a slight cloudiness with barium chloride test-solution. Then transfer the precipitate to a wet muslin strainer, allow it to drain, and express the water as completely as possible. Dissolve one-half of the tartaric acid in the distilled water, neutralize the solution exactly with ammonia water, then add the other half of the tartaric acid, and dissolve it by the application of a gentle heat. Now add the moist ferric hydrate in successive portions, stirring constantly, and continue the heat, which should not exceed 60° C. (140° F.), until the hydrate is dissolved. Filter the solution while hot, evaporate it in a porcelain vessel, at or below the above-mentioned temperature, to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light"—(U. S. P.).

In this process ammonium tartrate is first formed by neutralizing one-half the tartaric acid with ammonia water, and this by the further addition of acid, becomes a bitartrate. This is then digested with freshly made ferric hydroxide, the solution filtered, and cautiously evaporated, the double salt being then dried and scaled.

Description and Tests.—The official salt forms "thin, transparent scales, varying in color from garnet-red to reddish-brown, without odor, and having a sweetish, slightly ferruginous taste; slightly deliquescent in the air. Very soluble in water; insoluble in alcohol. When strongly heated, the salt chars, emits fumes having an odor of burning sugar, and finally leaves a residue of ferric oxide, which should not have an alkaline reaction upon litmus paper (absence of citrates or tartrates of the fixed alkalies). The aqueous solution of the salt is neutral to litmus paper, and is not precipitated, but rendered darker in color by ammonia water. With potassium ferrocyanide T.S. it does not afford a blue color or precipitate, unless it be acidulated with hydrochloric acid. When heated with potassium or sodium hydrate T.S., it yields a brownish-red precipitate, and vapor of ammonia is evolved. If a 10 per cent solution of the salt be deprived of its iron by boiling it with an excess of potassium or sodium hydrate T.S., the filtrate, when slightly acidulated with acetic acid, will gradually deposit a white, crystalline precipitate. If 0.56 (0.5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 Cc.) in 15 Cc. of water and 2 Cc. of hydrochloric acid, and after the addition of 1 Gm. of potassium iodide, the mixture be

kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require about 17 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 1 per cent of metallic iron)"—(U. S. P.).

Action, Medical Uses, and Dosage.—A mild chalybeate, containing a small proportion of iron, but having the advantage of free solubility. Dose, 5 to 30 grains.

Related Compound.—**FERRI ET QUININÆ TARTRAS**, *Iron and quinine tartrate, Ferro-tartrate of quinine.* Take of crystallized tartaric acid, distilled water, each, by weight, 2 ounces; moist hydrated oxide of iron (ferric hydroxide), pure quinine, of each, a sufficient quantity. Boil the tartaric acid and the distilled water together in a glass or porcelain vessel; as soon as the acid is dissolved, add the iron as long as the fluid will dissolve it. Heat the mixture until the deep blood-red fluid becomes clear, and then add the quinine until the fluid ceases to dissolve it. Evaporate the solution by means of gentle heat to the consistence of thick syrup, and spread it in thin layers on glass to dry (Prof. J. M. Sanders). This salt is much more soluble than the citrate of iron and quinine. It forms in scales of a beautiful crimson color. It is incompatible with astringent vegetable infusions, strong acids, alkalies, and their carbonates. The ferro-tartrate of quinine is a valuable tonic, and may be used with benefit in *chlorosis*, *amenorrhœa*, *debility*, *anemia*, and during the remissions or intermissions from *fever*; also in *scrofula*, and whenever the union of quinine with a chalybeate is indicated. The dose is from 3 to 5 grains, 3 times a day, either in solution or in the form of pill.

FERRI ET POTASSII TARTRAS (U. S. P.)—IRON AND POTASSIUM TARTRATE.

SYNONYMS: *Potassio-ferric tartrate, Tartarated iron, Tartarized iron, Ferro-tartrate of potassium, Ferrum tartaratum, Ferri potassio-tartras, Ferrum tartarizatum, Ferri-Kali tartaricum, Tartaras ferrico-potassicus, Tartaras potassio-ferricus, Tartaras ferrico-kalicus.*

Preparation.—"Solution of ferric sulphate, one hundred cubic centimeters (100 Cc.) [3 fl̄3, 183 M]; potassium bitartrate, thirty-eight grammes (38 Gm.) [1 oz. av., 149 grs.]; distilled water, three hundred cubic centimeters (300 Cc.) [10 fl̄3, 69 M]; ammonia water, water, each, a sufficient quantity. To one hundred and ten cubic centimeters (110 Cc.) [3 fl̄3, 345 M] of ammonia water, previously diluted with two hundred and fifty cubic centimeters (250 Cc.) [8 fl̄3, 218 M] of cold water, add, under constant stirring, the solution of ferric sulphate, previously diluted with thirteen hundred cubic centimeters (1300 Cc.) [43 fl̄3, 460 M] of cold water. When the precipitate has subsided, draw off the clear, supernatant liquid by means of a siphon, then mix the precipitate intimately with about fifteen hundred cubic centimeters (1500 Cc.) [50 fl̄3, 346 M] of cold water, again draw off the clear liquid, and repeat the washing with water in the same manner until the decanted liquid gives not more than a slight cloudiness with barium chloride test solution. Then transfer the precipitate to a wet muslin strainer, allow it to drain, and express the water as completely as possible. Mix the potassium bitartrate with the distilled water, in a porcelain vessel, heat the mixture, on a water-bath, to a temperature not exceeding 60° C. (140° F.), and gradually add the moist ferric hydrate, stirring constantly until it is dissolved. Filter the liquid while hot, and let the filtrate stand in a cool, dark place for 24 hours. Then stir it well with a porcelain or glass spatula, so that the precipitate which has formed in it may be thoroughly incorporated with the liquid. Now add, very cautiously, just enough ammonia water to dissolve the precipitate, evaporate the solution in a porcelain vessel, at or below the above-mentioned temperature, to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light"—(U. S. P.).

This process very properly directs the addition of ammonia water in order to render the compound soluble, as recommended by G. H. Charles Klie (*Amer. Jour. Pharm.*, 1876, p. 170). J. U. Lloyd has shown (*New Remedies*, 1879, p. 324) that an excess of ammonia will cause darkening of the solution and the formation of a gelatinous tarry precipitate, and that it is absolutely necessary to restrict the ammonia water to the amount necessary to redissolve the reddish precipitate. This process had been used by him in a manufacturing way for several years.

Description and Tests.—"Thin, transparent scales, varying in color from garnet-red to reddish-brown, without odor, and having a sweetish, slightly ferruginous taste; slightly deliquescent in the air. Very soluble in water; insoluble in alcohol. When strongly heated, the salt chars, emits fumes having an odor resembling that of burning sugar, and finally leaves a dark-brown residue, having a strongly alkaline reaction, and effervescing with acids (distinction from iron and ammonium tartrate). The aqueous solution of the salt is neutral to litmus paper, and is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide T.S. it does not afford a blue color or precipitate unless it be acidulated with hydrochloric acid. When heated with potassium or sodium hydrate T.S., it yields a brownish-red precipitate, and a slight odor of ammonia is evolved. If a 10 per cent solution of the salt be deprived of its iron by boiling it with an excess of potassium or sodium hydrate T.S., the filtrate, when slightly acidulated with acetic acid, will gradually deposit a white, crystalline precipitate. If 0.56 (0.5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 Cc.) in 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require about 15 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 1 per cent of metallic iron)"—(U. S. P.). Of the ferric scale salts, this is one of the richest in iron. Some regard it as a double salt whose formula is $\text{Fe}_2(\text{C}_2\text{H}_3\text{O}_6)_3 + \text{K}_2\text{C}_2\text{H}_3\text{O}_6 + \text{H}_2\text{O}$. Flückiger regards its composition as $\text{C}_2\text{H}_3\text{O}_6\text{K}_2 + \text{C}_2\text{H}_3\text{O}_6(\text{Fe}_2\text{O}_3) + \text{H}_2\text{O}$ (*Pharm. Chemie.*, 1879, p. 848).

Action, Medical Uses, and Dosage.—On account of its pleasant taste and lack of marked astringency, and its kindly action upon the gastro-intestinal tract, as well as the large proportion of iron it contains, this is regarded as one of the most valuable of the iron compounds. Constipation is not so likely to follow its administration as from other chalybeate preparations. Dose, 5 to 20 grains, in solution, before meals.

FERRI ET QUININÆ CITRAS (U. S. P.)—IRON AND QUININE CITRATE.

SYNONYMS: *Ferri et quiniæ citras, Citras ferrico-quinicus.*

Preparation.—"Ferric citrate, eighty-five grammes (85 Gm.) [3 ozs. av.]; quinine, dried at 100° C. (212° F.), to a constant weight, twelve grammes (12 Gm.) [185 grs.]; citric acid, three grammes (3 Gm.) [46 grs.]; distilled water, a sufficient quantity to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Dissolve the ferric citrate in one hundred and sixty cubic centimeters (160 Cc.) [5 fl. 3, 197 ml.] of distilled water, by heating on a water-bath, at a temperature not exceeding 60° C. (140° F.). To this solution add the quinine and citric acid, previously triturated with twenty cubic centimeters (20 Cc.) [325 ml.] of distilled water, and stir constantly until the quinine and citric acid are dissolved. Lastly, evaporate the solution, on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light"—(U. S. P.).

The process employed by the *British Pharmacopœia* is complicated, and the salt, in consequence of the use of ammonia in its preparation, is much more soluble than that of the U. S. P.

Description and Tests.—Citrate of iron and quinine varies in solubility and color (yellow-green to brown-red), according to the method of producing it. The salt of the *British Pharmacopœia* has a greenish, golden-yellow hue. The official salt of the U. S. P. has never been in great demand on account of its slow solubility, the soluble iron and quinine citrate being preferred (see *Ferri et Quininæ Citras Solubilis*). The salt should not be exposed to sunlight.

"Thin, transparent scales, of a reddish-brown color, without odor, and having a bitter, mildly ferruginous taste; slowly deliquescent in damp air. Slowly but completely soluble in cold water, more readily soluble in hot water, and but partially soluble in alcohol. Its solubility is diminished by age. When strongly

heated the salt chars, and finally leaves a residue of ferric oxide, which should not have an alkaline reaction upon litmus paper (absence of citrates or tartrates of the fixed alkalis). The aqueous solution of the salt has an acid reaction. On the addition of a slight excess of ammonia water the color of the solution is deepened, and a white, curdy precipitate is produced. The filtrate from this precipitate does not afford a blue color with potassium ferrocyanide T.S., unless it be acidulated with hydrochloric acid. Another portion of the filtrate, treated with an excess of potassium or sodium hydrate T.S., deposits a brownish-red precipitate. If a 10 per cent solution of the salt be deprived of its iron and quinine by boiling it with an excess of potassium or sodium hydrate T.S., and the filtrate slightly acidulated with acetic acid, a portion of the cooled liquid, mixed with a little calcium chloride T.S., and again heated to boiling, gradually deposits a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for some time, should not deposit a white, crystalline precipitate (absence of tartrate)"—(U. S. P.).

ESTIMATION OF THE QUININE.—"Dissolve 1.12 (1.176) Gm. of iron and quinine citrate in a capsule, with the aid of a gentle heat, in 20 Cc. of water. Transfer the solution, together with the rinsings of the capsule, to a separator, allow the liquid to become cold, then add 5 Cc. of ammonia water and 10 Cc. of chloroform, and shake. Allow the liquids to separate, draw off the chloroform layer, and shake the residuary liquid a second and a third time with 10 Cc. of chloroform. Allow the combined chloroformic extracts to evaporate spontaneously, in a tared capsule, and dry the residue at a temperature of 100° C. (212° F.), to a constant weight. This residue should weigh not less than 0.1288 Gm. (corresponding to at least 11.5 per cent of dried quinine), and should conform to the reactions and tests of quinine (see *Quinina*)"—(U. S. P.).

ESTIMATION OF THE IRON.—"Heat the aqueous liquid, from which the quinine has been removed in the manner just described, on a water-bath, until the odor of chloroform and ammonia has disappeared, allow it to cool, and dilute it with water to the volume of 50 Cc. Transfer 25 Cc. of the liquid to a glass-stoppered bottle (having the capacity of about 100 Cc.), add 2 Cc. of hydrochloric acid and 1 Gm. of potassium iodide, and allow the mixture to stand for half an hour at a temperature of 40° C. (104° F.). After it has been allowed to cool, and been mixed with a few drops of starch T.S., it should require about 14.5 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 1 per cent of metallic iron)"—(U. S. P.).

Action, Medical Uses, and Dosage.—A valuable tonic, useful in all cases where iron and quinine are indicated, and especially in the *anemia* following *malarial fevers*. Dose, 5 to 10 grains, in solution or pill, repeated 3 times a day.

Related Compound.—**FERRI ET QUININÆ CITRAS CUM STRYCHNINA**, *Iron and quinine citrate with strychnine*, *Ferri et quininæ strychninæque citras*. Take of citrate of iron and quinine, 490 grains; crystals of strychnine, citric acid, each, 5 grains; water, 5 fluid ounces. Dissolve the citrate of iron and quinine in $4\frac{1}{2}$ fluid ounces of the water, and, having dissolved the strychnine and citric acid in the remaining $\frac{1}{2}$ fluid ounce of water by boiling, mix the solutions, evaporate to a syrupy consistence, and spread on glass plates to dry in scales. One grain of strychnine, 20 grains of quinine, and 79 grains of citrate of iron, are contained in each 100 grains of this preparation. The scales exactly resemble those of citrate of iron and quinine, but have a more persistently bitter taste. The presence of strychnine may be detected in the residue from the evaporation of the chloroformic solution of the alkaloids by the usual color tests. This may be used in all cases of *nervous debility*, *anemia*, *chlorosis*, *dyspepsia*, *torpor of liver*, *constipation*, etc., in which the use of iron, quinine, and strychnine is indicated; it, together with the one later to be described (*Ferri et Strychninæ Citras*), is the safest, if not the best, means of exhibiting strychnine. Five grains of the preparation contain $\frac{1}{10}$ of a grain of strychnine. The dose is from 2 to 5 grains, 2 or 3 times a day.

FERRI ET QUININÆ CITRAS SOLUBILIS (U. S. P.)—SOLUBLE IRON AND QUININE CITRATE.

Preparation.—"Ferric citrate, eighty-five grammes (85 Gm.) [3 ozs. av.]; quinine, dried at 100° C. (212° F.), to a constant weight, twelve grammes (12 Gm.) [185 grs.]; citric acid, three grammes (3 Gm.) [46 grs.]; ammonia water, distilled

water, each, a sufficient quantity to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Dissolve the ferric citrate in one hundred and sixty cubic centimeters (160 Cc.) [5 fl̄, 197 M.] of distilled water, by heating on a water-bath at a temperature not exceeding 60° C. (140° F.). To this solution add the quinine and citric acid, previously triturated with twenty cubic centimeters (20 Cc.) [325 M.] of distilled water and stir constantly until the quinine and citric acid are dissolved. Then add gradually and with constant stirring, fifty cubic centimeters (50 Cc.) [1 fl̄, 332 M.], or a sufficient quantity of ammonia water, so that, after the addition of each portion of the latter, the precipitated quinine will be redissolved and the liquid acquire a greenish-yellow tint. Lastly, evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light"—(U. S. P.). This salt became official in the U. S. P. of 1890.

Description and Tests.—"Thin, transparent scales, of a greenish, golden-yellow color, without odor, and having a bitter, mildly ferruginous taste; deliquescent in damp air. Rapidly and completely soluble in cold water, but only partially soluble in alcohol. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which should not have an alkaline reaction upon litmus paper (absence of citrates or tartrates of the fixed alkalies). The aqueous solution of the salt has a slightly acid reaction. On the addition of a slight excess of ammonia water the color of the liquid is deepened, and a white, curdy precipitate is produced. If a portion of the filtrate from this precipitate be mixed with some potassium ferrocyanide T.S., it does not afford a blue color or precipitate, unless it be acidulated with hydrochloric acid. Another portion of the filtrate, treated with an excess of potassium or sodium hydrate T.S., gives a brownish-red precipitate. If a portion of the salt be heated with potassium or sodium hydrate T.S., vapor of ammonia will be evolved. If a 10 per cent solution of the salt be deprived of its iron and quinine by boiling it with an excess of potassium or sodium hydrate T.S., and the filtrate slightly acidulated with acetic acid, a portion of the cooled liquid, mixed with a little calcium chloride T.S., and again heated to boiling, will gradually deposit a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for some time, should not give a white, crystalline precipitate (absence of tartrate). Soluble iron and quinine citrate, when assayed for quinine and iron by the method described under *Ferri et Quininæ Citras*, should respond to the requirements for the latter"—(U. S. P.).

This preparation differs from the preceding in its ready solubility owing to the ammonia used in its production. It is the salt that should be used in making solutions of iron and quinine citrate. The ammonia-free salt (*Ferri et Quininæ Citras*) is, however, better adapted for pills.

Action, Medical Uses, and Dosage.—Same as for *Ferri et Quininæ Citras*, which see.

FERRI ET STRYCHNINÆ CITRAS (U. S. P.)—IRON AND STRYCHNINE CITRATE.

SYNONYM: *Ferri et strychninæ citras* (U. S. P., 1870).

Preparation.—"Iron and ammonium citrate, ninety-eight grammes (98 Gm.) [3 ozs. av., 200 grs.]; strychnine, one gramme (1 Gm.) [15.4 grs.]; citric acid, one gramme (1 Gm.) [15.4 grs.]; distilled water, one hundred and twenty cubic centimeters (120 Cc.) [4 fl̄, 28 M.], to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Dissolve the iron and ammonium citrate in one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M.] of distilled water, and the strychnine, together with the citric acid, in twenty cubic centimeters (20 Cc.) [325 M.] of distilled water. Mix the two solutions, evaporate the mixture by means of a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of a syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from the light"—(U. S. P.).

This preparation is merely a mixture of ammonio-ferric citrate and strychnine citrate. It should not be prescribed in solution, as Dr. E. R. Squibb has

shown (*Ephemeris*, 1888), that it rapidly decomposes, even in a few hours, throwing down a white deposit. Strychnine, to the extent of 50 per cent, was found in this sediment, hence the danger of using it in solution. If it must be used in this manner the liquid should be well shaken before taking each dose. It may be given in pill form. The salt should contain about 1 per cent of strychnine.

Description.—“Thin, transparent scales, varying in color from garnet-red to yellowish-brown, without odor, and having a bitter, slightly ferruginous taste; deliquescent in damp air. Readily and completely soluble in water, but only partly soluble in alcohol. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which should not have an alkaline reaction upon litmus paper (absence of citrates or tartrates of the fixed alkalies). The aqueous solution of the salt is slightly acid to litmus paper, and is not immediately precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide T.S., it does not yield a blue color or precipitate, unless it be acidulated with hydrochloric acid. On heating it with potassium or sodium hydrate T.S., a brownish-red precipitate is produced, and vapor of ammonia evolved. If a 10 per cent solution of the salt be deprived of its iron and strychnine by boiling it with an excess of potassium or sodium hydrate T.S., and the filtrate slightly acidulated with acetic acid, a portion of the cooled liquid mixed with a little calcium chloride T.S., and again heated to boiling, will gradually deposit a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for some time, should not deposit a white, crystalline precipitate (absence of tartrate)”—(*U. S. P.*).

ESTIMATION OF THE STRYCHNINE.—“Dissolve 2.24 (2.2352) Gm. of iron and strychnine citrate, in a separator in 15 Cc. of water, add 5 Cc. of ammonia water, and 10 Cc. of chloroform, and shake. Allow the liquids to separate, draw off the chloroform layer, and shake the residuary liquid a second and a third time with 10 Cc. of chloroform. Allow the combined chloroformic extracts to evaporate spontaneously in a tared capsule, and dry the residue at a temperature of 100° C. (212° F.), to a constant weight. This residue should weigh not less than 0.02 Gm. nor more than 0.0224 Gm. (corresponding to not less than 0.9 nor more than 1 per cent of strychnine), and should respond to the reactions and tests of strychnine (see *Strychnina*)”—(*U. S. P.*).

ESTIMATION OF THE IRON.—“Heat the aqueous liquid, from which the strychnine has been removed in the manner just described, on a water-bath, until the odor of chloroform and ammonia has disappeared, allow it to cool, and dilute it with water to the volume of 100 Cc. Transfer 25 Cc. of the liquid to a glass-stoppered bottle (having the capacity of about 100 Cc.), add 2 Cc. of hydrochloric acid and 1 Gm. of potassium iodide, and allow the mixture to stand for half an hour, at a temperature of 40° C. (104° F.). After it has been allowed to cool, and been mixed with a few drops of starch T.S., it should require about 16 Cc. of decinormal sodium hyposulphite V.S., to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 1 per cent of the metallic iron)”—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This preparation is useful in *debility, dyspepsia* arising from atony, *chlorosis, chorea, suppressed menstruation*, etc. Five grains contain $\frac{1}{10}$ of a grain of strychnine. The dose is from 1 to 4 grains in pill, cautiously increased to 6 grains, 2 or 3 times a day. It should not be given in solution.

FERRI FERROCYANIDUM.—FERRIC FERROCYANIDE.

FORMULA: $\text{Fe}_3\text{Cy}_{12} = \text{Fe}_3(\text{CN})_{12} = \text{Fe}_3(\text{FeCy}_6)_2 = \text{Fe}_3\text{Fe}(\text{CN})_6$. **MOLECULAR WEIGHT:** 858.8.

SYNONYMS: *Prussian blue, Paris blue, Williamson's blue, Ferrocyanide of iron, Ferrocyanuret of iron, Ferri ferrocyanuretum, Insoluble Prussian blue, Ferrum ferrocyanatum, Ferrum borussicum, Ferrum zooticum, Cæruleum borussicum, Cyanuretum ferrocærricum, Ferrocyanidum ferricum.*

Preparation.—This is formed by precipitating a solution of ferrocyanide of potassium (yellow prussiate of potash, $\text{Fe}_3\text{Cy}_{12}\text{K}_6$ or $2\text{FeCy}_6\text{K}_3$), with a solution of ferric sulphate or ferric chloride in excess. The *U. S. P.*, of 1870, directed potassium

ferrocyanide, 9 troy ounces; solution of ferric sulphate, 1 pint; water, 3 pints. The potassium salt to be dissolved in 2 pints of the water, and the iron solution in 1 pint. Add the solution of the potassium salt gradually with constant stirring, to the iron solution, filter, and wash the blue precipitate with boiling water, dry, and powder the product. The following reaction takes place: $3\text{Fe}_2\text{Cy}_{12}\text{K}_3 + 4\text{Fe}_2\text{Cl}_6 = 24\text{KCl} + 2\text{Fe}_3(\text{FeCy}_{12})_2$. To free the compound from adherent potassium salt considerable washing is required. It retains about 18 molecules of H_2O when dried at a temperature near 40°C . (104°F .), but on subjecting it to a higher heat this is gradually dissipated.

Description.—Prussian blue, when well made, is of a beautiful dark-blue color, without taste or odor. The broken surfaces of the fragments are of a beautiful bronze color, and the compound when triturated, yields a handsome deep-blue powder. It is not dissolved by water, alcohol, ether, oils, or diluted acids. It is decomposed by the concentrated acids, with a variety of phenomena. The alkalis also decompose it, forming solution of ferrocyanides and a precipitate of ferric hydroxide. Heated in the air, it burns slowly, leaving ferric oxide and earthy matters if any are present. Oxalic and other organic acids dissolve it, forming a beautiful deep-blue solution, the solution in the former being called *Washing-blue*, and is often known as *Soluble Prussian blue* (not to be confused with the *True soluble Prussian blue* of Berzelius, for which, see *Ferric Potassium Ferrocyanide*). When Prussian blue is boiled with diluted hydrochloric acid, filtered, and ammonia added to it, no precipitation of hydroxides of aluminum, lead, etc., nor blue coloration (due to copper), takes place if the drug be pure.

Action, Medical Uses, and Dosage.—Prussian blue is tonic, sedative, and febrifuge; and was introduced as a remedy in *periodic diseases*, in conjunction with sulphate of quinine, by the late Prof. I. G. Jones, who used it with great success in the treatment of these diseases. He did not regard the febrile or inflammatory symptoms as contraindicating its use, provided the disease was, in the least degree, of a periodical character. It has been successfully used in *intermittent*, *congestive*, *bilious*, and *typhoid fevers*, especially during the remissions, and also in *typhoid pneumonia*; the dose is 3 or 4 grains, combined with the same quantity of sulphate of quinine, to be repeated every 3, 4, or 5 hours, according to the nature of the case. Prussian blue has likewise been successfully used in *diarrhœa*, *summer complaint of children*, *pertussis*, *dyspepsia*, *epilepsy*, *hysteria*, *chorea*, and *facial neuralgia*. It is now seldom employed. The dose is usually from 1 to 5 grains, 3 times a day.

Related Compounds.—**POTASSIUM FERRI-FERROCYANIDE** ($\text{K}_3\text{Fe}^{\text{III}}[\text{C}_6\text{N}_6]\text{Fe}^{\text{II}}$), *Ferric potassium ferrocyanide*. This is the *True soluble Prussian blue* of Berzelius, and is prepared by pouring a solution of ferric sulphate or chloride into a solution of potassium ferrocyanide in excess, and washing the precipitate to free it from sulphate or chloride of potassium or other foreign substances. The salt thus made will dissolve in pure water, but not in salt solutions; hence it is precipitated from its aqueous solution by various salts. It is not used in medicine (see Lloyd's *Chem. of Med.*).

POTASSIUM FERRO-FERRICYANIDE ($\text{K}_3\text{Fe}_2[\text{Fe}_2\text{Cy}_{12}]$), a soluble substance identical in composition with the foregoing, is produced when a solution of a ferrous salt is added to an excess of a solution of ferricyanide of potassium (red prussiate of potash).

FERRICYANIDUM FERROSUM ($\text{Fe}_2[\text{Fe}_2\text{Cy}_{12}]$), *Turnbull's blue*, *Ferrous ferricyanide*.—This is the blue precipitate produced when ferricyanide of potassium (red prussiate of potash) is added to the solution of a ferrous salt. The reaction is made use of in testing in order to distinguish between *ferrous* and *ferric* salts.

In this connection it is probably well to briefly recapitulate the color reactions that take place between ferro- and ferricyanide of potassium on the one hand, and ferrous and ferric salts on the other. Ferrocyanide and ferric salt, blue precipitate (soluble Prussian blue); ferrocyanide and ferrous salt, white precipitate, turning blue rapidly when exposed to the air; ferricyanide and ferrous salt, blue precipitate (Turnbull's blue); ferricyanide and ferric salt, brown solution.

FERRI HYPOPHOSPHIS (U. S. P.)—FERRIO HYPOPHOSPHITE.

FORMULA: $\text{Fe}_2(\text{PH}_2\text{O}_2)_2$. MOLECULAR WEIGHT: 507.04.

SYNONYMS: *Hypophosphite of iron*, *Ferrum hypophosphorosum*, *Hypophosphis ferricus*.

Preparation.—This preparation may be made by double decomposition between solution of ferric chloride or ferric sulphate, and solution of hypophos-

phite of sodium. If the ferric salt is free from excess of acid, the hypophosphite of iron will separate as a precipitate when the solutions are mixed, after which it may be washed with distilled water and then dried. Owing to a certain degree of solubility of the salt in water, however, much is lost in the washings. It is customary in practice to use *ferrous hypophosphite*, as a component of the popular pharmaceutical preparation, *Syrup of the Hypophosphites*. In this case the solution of ferrous hypophosphite is made by double decomposition between solution of hypophosphite of calcium and solution of ferrous sulphate (J. U. Lloyd, in *Chemistry of Medicines*). An acceptably pure ferric hypophosphite may be prepared according to Mr. F. X. Moerk, by dissolving in a flask calcium hypophosphite (30 Gm. = 1 oz. av., 25 grs.) in distilled water (100 Cc. = 3 fl. 3, 183 M). Gradually add solution of ferric chloride (49.5 Gm. = 1 oz. av., 326 grs.). Agitate well as each portion is added. After allowing the mixture to stand for 3 days, frequently shaking it, filter and wash the precipitate well. This process is based upon the observation that the flocculent precipitate of ferric hypophosphite becomes crystalline upon prolonged standing. In this condition it is less soluble in water, and can thus be conveniently washed without much loss (*Amer. Jour. Pharm.*, 1889, p. 393).

The *National Formulary* directs as follows: "*Formulary number, 183: FERRI HYPOPHOSPHIS (N. F.), Hypophosphite of iron, Ferric hypophosphite.*—Iron and ammonium sulphate (*U. S. P.*), in perfect crystals, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; sodium hypophosphite, sixty-seven grammes (67 Gm.) [2 ozs. av., 159 grs.]; distilled water, a sufficient quantity. Dissolve the iron and ammonium sulphate in four hundred cubic centimeters (400 Cc.) [13 fl. 3, 252 M], and the sodium hypophosphite in one hundred and twenty-five cubic centimeters (125 Cc.) [4 fl. 3, 109 M] of distilled water, and, if necessary, filter each solution. Then mix them, and stir thoroughly; after a short time transfer the mixture to a close linen or muslin strainer, and wash the precipitate with distilled water, until the washings run off tasteless. Transfer the strainer to a warm place and when the contents are dry, preserve them for use. Hypophosphite of iron (ferric) may also be prepared in the following manner:

"Calcium hypophosphite, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; solution of chloride of iron (*U. S. P.*), distilled water, of each, a sufficient quantity. Dissolve the calcium hypophosphite in twelve hundred cubic centimeters (1200 Cc.) [40 fl. 3, 277 M] of distilled water, and filter the solution. To this add solution of chloride of iron, in small portions, stirring well each time, and allowing the precipitate to subside before adding a fresh portion. Toward the end, remove a small quantity of the clear supernatant liquid, add to it some solution of chloride of iron diluted with ten times its volume of water, and observe whether any turbidity occurs either at once or after a few minutes. If it remains clear, the precipitation may be regarded as complete. Then transfer the mixture to a close linen or muslin strainer, and wash the precipitate with distilled water until the washings run off tasteless. Transfer the strainer to a warm place, and, when the contents are dry, preserve them for use. *Note.*—Hypophosphite of iron is rendered soluble in water by mixing it with about an equal weight of potassium citrate, or some other alkali citrate. Theoretically, 100 grammes of iron and ammonium sulphate will yield 51.9 grammes, and 100 grammes of calcium hypophosphite will yield 85.3 grammes of dry hypophosphite of iron (ferric)"—(*Nat. Form.*).

Description and Tests.—The *U. S. P.* describes hypophosphite of iron as "a white or grayish-white powder, odorless and nearly tasteless; permanent in the air. Only slightly soluble in water, more readily in the presence of hypophosphorous acid, or in a warm, concentrated solution of an alkali citrate, forming with the latter a green solution. When strongly heated in a dry test-tube, the salt evolves spontaneously inflammable hydrogen phosphide gas, and, on complete ignition, leaves a residue of ferric pyrophosphate. The salt is readily oxidized by nitric acid or other oxidizing agents. If to 0.5 Gm. of the salt 5 Cc. of acetic acid be added, no effervescence should occur (absence of carbonate), and if the mixture be subsequently heated to boiling, the filtrate, upon cooling, should afford no turbidity with ammonium oxalate T.S. (absence of calcium). If 0.5 Gm. of the salt be boiled with 10 Cc. of potassium or sodium hydrate T.S., a reddish-brown precipitate will be produced; and if to the filtrate from the latter, slightly

acidulated with hydrochloric acid, magnesia mixture be added, and subsequently an excess of ammonia water, no crystalline precipitate should be produced (absence of phosphate). If 1 Gm. of ferric hypophosphite be mixed with 10 Cc. of water, then 10 Cc. of diluted sulphuric acid and 50 Cc. of decinormal potassium permanganate V.S. added, and the mixture boiled for 15 minutes, it should require not more than 3 Cc. of decinormal oxalic acid V.S. to discharge the red color (corresponding to at least 98.1 per cent of the pure salt)"—(U. S. P.).

"Ferric hypophosphite should be kept in well-stoppered bottles"—(U. S. P.).

Action, Medical Uses, and Dosage.—This salt is preferably administered in syrup, though it may be given in pill or powder. It is used in *anemic states* associated with cerebral enfeeblement. Dose, 5 to 10 grains.

FERRI IODIDUM SACCHARATUM (U. S. P.)—SACCHARATED FERROUS IODIDE.

FORMULA (Ferrous iodide): FeI_2 . MOLECULAR WEIGHT: 308.94.

SYNONYMS: *Ferrum iodatum saccharatum*, *Saccharated iodide of iron*.

Preparation.—"Take of iron, in the form of fine, bright wire, and cut into small pieces, six grammes (6 Gm.) [93 grs.]; reduced iron, one gramme (1 Gm.) [15.5 grs.]; iodine, seventeen grammes (17 Gm.) [262 grs.]; distilled water, sugar of milk, recently dried, each, a sufficient quantity to make one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Mix the iron wire, iodine, and twenty cubic centimeters (20 Cc.) [325 M.] of distilled water in a flask of thin glass, shake the mixture occasionally, until the reaction ceases, and the solution has acquired a green color and lost the smell of iodine; then filter it through a small wetted filter into a porcelain capsule containing forty grammes (40 Gm.) [1 oz. av., 180 grs.] of sugar of milk. Rinse the flask and iron wire with a little distilled water, pass the rinsings through the filter into the capsule, and evaporate on a water-bath, with frequent stirring, until a dry mass remains. Transfer this quickly to a heated iron mortar, reduce it to powder, and mix it intimately, by trituration, with the reduced iron and enough sugar of milk to make the final product weigh one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Transfer the powder at once to small and perfectly dry bottles, which should be securely stoppered, and kept in a cool and dark place"—(U. S. P.).

This preparation should contain 20 per cent of ferrous iodide. Iron and iodine react upon each other with the production of heat, yielding ferrous iodide (FeI_2). The water merely acts as a solvent of the product, and to mitigate the violence of the reaction. Volatilization of iodine should be checked by immersion of the flask in cold water. On the other hand, should the reaction take place too slowly toward the close of the operation, a gentle heat may be applied. Some prefer to add the ingredients fractionally, and not all at one time, as directed in the official process. To do this the water and iodine may be placed in the flask, and the iron added gradually, allowing the reaction to nearly complete itself before adding a fresh portion. The object in adding the reduced iron at the close of the operation is to preserve the preparation, as, if any iodine is subsequently liberated, the iron will unite with it.

Description and Tests.—"A yellowish-white or grayish, very hygroscopic powder, without odor, and having a sweetish, ferruginous taste. Soluble in 7 parts of water at 15° C. (59° F.), forming a nearly clear solution, but only partially soluble in alcohol. When strongly heated, the compound swells up, evolves the odor of iodine and of burning sugar, and, on complete ignition, leaves a residue which should yield nothing soluble to water (absence of the salts of the fixed alkalies). The aqueous solution has a slightly acid reaction, and gives with potassium ferricyanide T.S. a blue precipitate. If the aqueous solution be mixed with a little starch T.S., and afterward with a few drops of chlorine water, it will assume a deep-blue color. This color should not be developed in the aqueous solution by starch T.S. alone (absence of free iodine). If 1.55 (1.5447) Gm. of saccharated ferrous iodide be dissolved in about 20 Cc. of water, in a small flask, and to this solution be successively added, first, 22 Cc. of decinormal silver nitrate V.S., then 5 Cc. of diluted nitric acid and 5 Cc. of ferric ammonium sulphate T.S.,

it should not require more than 2 Cc. of decinormal potassium sulphocyanate V.S. to produce a reddish-brown tint which persists after shaking (corresponding to about 20 per cent of pure ferrous iodide)"—(U. S. P.).

Action, Medical Uses, and Dosage.—The action and uses of saccharated iodide of iron are identically those of ferrous iodide. The influence of iodide of iron upon the system resembles that caused by the ferruginous salts more than that occasioned by iodine. As a tonic it improves the appetite, invigorates the digestive organs, and blackens the alvine evacuations, diminishing their offensive odor. Sometimes it acts as a laxative, but more generally as a diuretic. It is also tonic, alterative, and emmenagogue. It has been efficiently used in *scrofula*, *chlorosis*, *secondary syphilis*, *amenorrhœa*, *chronic rheumatism*, *chronic cutaneous diseases*, *fluor albus*, *asthenic dropsy*, *old visceral engorgements*, *atonic dyspepsia*, and in all cases where there is torpor in the system of nutrition, where there is paucity of red globules in the blood, and the fluid is too thin. On account of its tendency to decomposition when exposed to the air, it should always be given in solution or syrup (see *Liquor Ferri Iodidi* and *Syrupus Ferri Iodidi*). In the *anemia of scrofula*, *phthisis*, etc., it imparts strength, improves the appetite and digestion, and increases secretion. Here the syrup should be given with cod-liver oil. It has been given with marked success in *hydrocephalus*, and in *dysmenorrhœa*, and in *anemic scrofulous females*. From 5 to 10 drops of the syrup, 3 times a day, relieves the *incontinence of urine* in anemic children. Iodide of iron has, however, been given in pill form, being protected from deleterious agencies by the addition of gum and sugar, or tragacanth and honey (see *Amer. Jour. Pharm.*, XV., 71, and CIII., 138). The liquor ferri iodidi, evaporated to a proper consistence for making pills, would probably form a better mode of administering this salt in a solid state, than when made by the above process (see *Pilulæ Ferri Iodidi*). The dose of iodide of iron is 3 grains, gradually increased to 8 or 10 grains, 3 times a day.

Related Preparations.—*FERRI IODIDUM*, *Ferrous iodide*, *Ioduretum ferrosium*, *Iodide of iron*. Take of iodine, 2 ounces and 2 drachms; pure iron filings, 6 drachms; distilled water, cold, 4½ fluid ounces. By a former method, the iodine was mixed with the water, and the iron filings gradually added, with constant stirring of the mixture. This was then heated until it acquired a greenish hue, filtered, and evaporated to dryness in an iron vessel.

Messrs. T. and H. Smith subsequently directed as follows: Put the aforementioned ingredients into a flask, boil till the liquid loses its dark color, then filter it rapidly into another clean flask, and, without delay, place the flask over the flame of a gas-burner, and evaporate the liquid at a boiling heat. The ebullition is allowed to proceed until the liquid passes from a green shade into black. The iodide may now be obtained either as a crystallized hydrate, or in an amorphous anhydrous form; first, as a *crystallized hydrate* ($\text{FeI}_2 + 4\text{H}_2\text{O}$), by dipping an iron wire or glass rod into the liquid in the flask at short intervals, till, on removing and cooling, the iodide is found to form a dry and hard crust on the rod. When the evaporation has reached this point, remove the flask from the fire, and the fused iodide will crystallize on cooling. To obtain the *anhydrous iodide*, the evaporation must be carried still further. The period for bringing the application of heat to a close, may be judged of by occasionally placing a piece of cold glass over the mouth of the flask, and suspending the heat when moisture ceases to be condensed on the glass. A pure anhydrous, spongy, ferrous iodide will then be found in the flask, and may be removed by breaking the container. The compound should, without the least delay, be coarsely bruised in a warm, dry mortar, and then placed in small bottles and well corked (T. and H. Smith).

Iodide of iron is a dry, greenish-gray or greenish-black, crystalline mass, odorless, and of a sweetish, astringent taste, somewhat resembling iodine. Water or alcohol forms with it, when freshly made, a greenish solution having an acid reaction; in the air, on being kept, it deliquesces, forming ferric oxide and ferric iodide, and will not be wholly soluble, forming a yellow or brown solution. Gently warmed it melts, and by a further action of heat, water, and air, continually evolves iodine vapors, and leaves a grayish-brown mass, consisting of ferrous iodide, ferric iodide, and ferric oxide. If the dried mass be heated to redness, all the iodine is given off, and the iron remains as oxide. As regards the keeping qualities of this substance, see *Syrupus Ferri Iodidi*. The salt is *incompatible* with vegetable astringents, sodium, potassium hydroxide, and other alkalies, liquor calcis, metallic salts, etc.

DUPASQUIER'S PASTE.—Considerable use has been made of Dr. Dupasquier's paste, or pills of protiodide of iron (ferrous iodide); it is prepared as follows: Take of iodine, 121 grains; iron, 242 grains; distilled water, 378 grains. Introduce the whole into a small flask, which should be plunged during 8 or 10 minutes in water warmed to about 75° C. (167° F.), so that no portion of the iodine shall be volatilized. Agitate the mixture frequently. At first the liquid becomes brown, but soon becomes perfectly colorless, or, at most, retains a nearly imperceptible green hue. Filter rapidly, and pour the solution into an untinned iron vessel; add pure honey, 302 grains; evaporate rapidly, until a syrupy consistence is attained; then add at intervals, continually agitating with an iron spatula, powder of gum tragacanth, 184 grains. Form

into a mass, and divide into 200 pills; each pill contains about $\frac{1}{2}$ of a grain of protiodide of iron, and will remain a long time unaltered. BLANCARD'S PILLS are similar, but are sugar-coated as soon as made.

FERRIC IODATE, *Iodate of iron, Iodate of sesquioxide of iron* ($2\text{Fe}_2[\text{IO}_3]_4 \cdot \text{Fe}_2\text{O}_3 \cdot 24\text{H}_2\text{O}$).—Add solution of ferric chloride (5 fluid drachms), to water (4 fluid ounces). Precipitate this solution with another solution composed of potassium iodate (1 ounce) in water (10 fluid ounces). The precipitate is tasteless, does not attack the teeth, and has been recommended to take the place of iodide of iron.

FERRI LACTAS (U. S. P.)—FERROUS LACTATE.

FORMULA: $\text{Fe}(\text{C}_2\text{H}_3\text{O}_2)_2 + 3\text{H}_2\text{O}$. **MOLECULAR WEIGHT:** 287.34.

SYNONYMS: *Lactate of iron, Lactas ferrosus.*

Preparation.—The U. S. P. (1870) process consists in digesting a solution of lactic acid (1 ounce) in distilled water (1 pint) with iron filings ($\frac{1}{2}$ ounce) until the reaction ceases; filter into a porcelain vessel and crystallize. Evaporate the mother liquor to one-half in an iron vessel, filter hot, and set aside to obtain additional crystals. The following process is based upon the double decomposition ensuing between calcium lactate and ferrous sulphate: Take of calcium lactate, $12\frac{1}{2}$ ounces; pure crystallized ferrous sulphate, $8\frac{1}{2}$ ounces; boiling water, cold distilled water, of each, $62\frac{1}{2}$ ounces, by weight; lactic acid, a sufficient quantity. Dissolve the lactate of calcium in the boiling water; also dissolve the sulphate of iron in the cold distilled water; then filter each of these solutions, mix them in a vessel; feebly acidulate the mixture with lactic acid, and heat in a salt-water bath, constantly stirring until the completion of the double decomposition. The sulphate of calcium formed is to be removed by filtering, and the filtrate is to be quickly reduced to one-half by evaporation in an iron vessel (or, if porcelain be used, some iron filings must be added). Filter the concentrated liquid, and, on cooling, it forms crystals of lactate of iron, which should be washed with alcohol, and dried on bibulous paper (Lepage).

Lactate of iron was introduced to the profession by Gélis and Conté.

Description.—“Pale, greenish-white crusts, consisting of small, needle-shaped crystals, having a slight, peculiar odor, and a mild, sweetish, ferruginous taste. Slowly but completely soluble in 40 parts of water at 15°C . (59°F .), and in 12 parts of boiling water; freely soluble in a solution of an alkali citrate, yielding a green solution; almost insoluble in alcohol. When strongly heated, the salt froths up, gives out dense, white, acrid fumes, chars, and finally leaves a brownish-red residue. The aqueous solution of the salt has a greenish-yellow color, a slightly acid reaction, and gives with potassium ferricyanide T.S. a deep blue, and with potassium ferrocyanide T.S. a light blue precipitate”—(U. S. P.).

Tests.—“A 2 per cent aqueous solution of the salt should not afford with lead acetate T.S., nor, after acidulation with hydrochloric acid, with hydrogen sulphide T.S., more than a whitish opalescence (limit or absence of sulphate, chloride, citrate, tartrate, malate, etc., and of foreign metals). The aqueous solution, acidulated with nitric acid, should not afford more than a slight opalescence with barium chloride T.S., or with silver nitrate T.S. (limit of sulphate or chloride). If 25 Cc. of the aqueous solution (1 in 50), mixed with 5 Cc. of diluted sulphuric acid, be boiled for a few minutes, then precipitated by an excess of potassium or sodium hydrate T.S., the filtrate, mixed with a few drops of alkaline cupric tartrate V.S., and heated to boiling, should not afford a red precipitate (absence of sugar). If a portion of the salt be triturated with strong sulphuric acid, no offensive odor should be developed (absence of butyric acid), nor should any gas be evolved (absence of carbonate), and the mixture, after standing for some time, should not assume a brown color (absence of sugar, gum, or other readily carbonizable impurities). If 1 Gm. of the salt, contained in a porcelain crucible, be moistened with nitric acid, and carefully ignited, it should leave a residue of ferric oxide weighing not less than 0.270 nor more than 0.278 Gm. This residue should not have an alkaline reaction upon litmus paper, nor yield anything soluble to water (absence of foreign salts)”—(U. S. P.).

Action, Medical Uses, and Dosage.—Lactate of iron has been found efficient in anemia, amenorrhœa, dysmenorrhœa, and other diseases in which the preparations of iron are usually of service. The dose is from 1 to 3 grains, gradually increased

and repeating it at periods of 3 or 4 hours. As it is not superior to other chalybeates, its costliness will probably prevent it from coming into general use.

FERRI OXIDUM HYDRATUM (U. S. P.)—FERRIC HYDRATE.

FORMULA: $\text{Fe}_2(\text{OH})_6$. MOLECULAR WEIGHT: 213.52.

SYNONYMS: *Ferric hydroxide, Hydrated oxide of iron, Hydrated sesquioxide of iron, Moist peroxide of iron, Ferri peroxidum.*

Preparation.—"Solution of ferric sulphate, one hundred cubic centimeters (100 Cc.) [3 fl.℥, 183 Ml.]; ammonia water, one hundred and ten cubic centimeters (110 Cc.) [3 fl.℥, 345 Ml.]; water, a sufficient quantity. To the ammonia water, previously diluted with two hundred and fifty cubic centimeters (250 Cc.) [8 fl.℥, 218 Ml.] of cold water, add, under constant stirring, the solution of ferric sulphate, previously diluted with one thousand cubic centimeters (1000 Cc.) [33 fl.℥, 391 Ml.] of cold water. As soon as the precipitate has subsided, draw off the clear liquid by means of a siphon, then mix the precipitate intimately with about one thousand cubic centimeters (1000 Cc.) [33 fl.℥, 391 Ml.] of cold water, again draw off the clear liquid after subsidence of the precipitate, and repeat this operation, until a portion of the decanted liquid gives not more than a slight cloudiness with barium chloride test-solution. Finally transfer the precipitate to a wet muslin strainer, and, after it has drained, mix it with sufficient cold water to make the mixture weigh two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.].

"When ferric hydrate is to be made in haste, for use as an antidote, the washing may be performed more quickly, though less perfectly, by transferring the precipitate at once to a wet muslin strainer, pressing forcibly with the hands, until no more liquid passes, and then adding enough water to make the whole weigh about two hundred and fifty grammes (250 Gm.) [8 ozs. av., 358 grs.].

Note.—"The ingredients for preparing ferric hydrate as an antidote should always be kept on hand in bottles containing, respectively, two hundred cubic centimeters (200 Cc.) [6 fl.℥, 366 Ml.] of the solution of ferric sulphate, and two hundred and twenty cubic centimeters (220 Cc.) [7 fl.℥, 211 Ml.] of ammonia water. Ferric hydrate, thus prepared, is a brownish-red magma, wholly soluble in hydrochloric acid without effervescence"—(U. S. P.).

While the U. S. P. process directs the use of ammonia as a precipitant, that of *Br. Pharm.* directs solution of soda. The resulting preparation in the first instance is a tasteless, brown-red magma, while that of the latter is directed to be a tasteless, non-magnetic, brownish-red powder, containing but 10 per cent of moisture. Probably magnesia, which in itself has some antidotal power over arsenic, is a better precipitant than either ammonia or soda solution, when the preparation is to be used as an antidote (see next article, *Ferri Oxidum Hydratum cum Magnesia*). Two precautions must be observed in regard to the U. S. P. product if the preparation is to possess antidotal properties: First—*Heat* should be avoided in its preparation, the product being most effective when made at the ordinary temperature. Secondly—It should be *recently prepared*, and the magma, when rubbed with water, should be non-granular, forming a smooth mass readily and completely soluble in both acetic and hydrochloric acids, without effervescing, otherwise it refuses to unite with arsenous acid. Ferric hydroxide (U. S. P.) unites readily with the weaker acids, and has the important property of forming an insoluble compound with arsenous acid. If dried, in consequence of the loss of a portion of its water, it becomes an oxyhydrate ($\text{Fe}_2\text{O}_3[\text{OH}]_2$) of a reddish color, and incapable of uniting with arsenous acid; hence it is then of no value as an antidote to that poison. It has been proposed to keep the magma under water in order to retard this change, but even then, in a little time, it loses half of its combined water and becomes changed to a brick-red ferric oxyhydrate ($\text{Fe}_2\text{O}_3 \cdot \text{Fe}[\text{OH}]_2$). Excessive heat or freezing produces similar results. The small amount of ammonium sulphate remaining in the oxide, when prepared hurriedly as before directed, in a case of poisoning, is not objectionable. When the oxide is intended for the preparation of other ferruginous compounds, as, for instance, citrate of iron, it should be washed by displacement on a cloth filter, till the washings cease to be precipitated by chloride of barium.

Description.—Ferric hydroxide, as prepared by the above process, is a soft magma of a reddish-brown tint, practically odorless and tasteless, insoluble in water, but dissolving readily in hydrochloric acid, forming a golden-yellow solution. Heated to redness, it loses its water, and then combines with difficulty with arsenous acid. Effervescence with hydrochloric acid, indicates the presence of carbon dioxide; when the solution in hydrochloric acid is precipitated by ammonia water and the precipitate filtered, oxalate of ammonium will cause a precipitate in the filtrate if calcium be present. If the solution in hydrochloric acid gives a blue precipitate with ferricyanide of potassium, it contains ferrous oxide; if, after dissolving it in hydrochloric acid, there is a white, gelatinous residue, soluble in caustic potash, it is silica, arising from its probably being made with potassium hydroxide containing silica instead of with ammonia. An excess of ammonia water strikes a blue color when oxide of copper is present; should the color not be clear, supersaturate with acetic acid, and add solution of ferrocyanide of potassium, which causes a brownish-red precipitate if the smallest trace of copper be present.

Action, Medical Uses, and Dosage.—This agent is unfitted for the same therapeutical applications as the other iron compounds. It is, however, universally accepted as the antidote to be employed in cases of *arsenical poisoning*. Probably the ferrous arsenate acts by enveloping the particles of acid, thus rendering them insoluble, and preventing their absorption until an emetic may be administered or the stomach pump used. It may be given freely in tablespoonful doses every 5 or 10 minutes, followed by means to evacuate the stomach.

Related Oxides.—**FERRI PEROXIDUM HYDRATUM** ($\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$, or $\text{Fe}_2\text{O}_3[\text{OH}]_2$). Molecular Weight: 177.80. *Ferric oxyhydrate, Hydrous peroxide of iron, Ferrum oxydatum fuscum, Ferric hydricum, Oxydum ferricum hydratum, Rubigo, Ferrugo.* This deep reddish-brown powder is obtained by drying the moist ferric hydrate (hydroxide) at a heat not above 100°C . (212°F). It contains about 10 per cent of moisture. It should completely dissolve in diluted hydrochloric acid without effervescence. Heated to dull redness in a test tube it gives off moisture (*Br. Pharm.*, 1867). It is scarcely soluble in acetic acid. The brown *hematites*, occurring in nature as minerals, are composed of ferric hydroxides.

FERRI OXIDUM NIGRUM, Black oxide of iron (Fe_3O_4 , or $\text{FeO} \cdot \text{Fe}_2\text{O}_3$), *Ferri oxidum magneticum, Magnetic oxide of iron, Ferroso-ferric oxide, Ferrum oxydatum magneticum, Ethiops martial, Martial Ethiops, Oxydum ferroso-ferricum.*—Take of sulphate of iron, 6 ounces; sulphuric acid (commercial), $2\frac{1}{2}$ fluid drachms; pure nitric acid, $4\frac{1}{2}$ fluid drachms; stronger aqua ammoniae, 4 fluid drachms; boiling water, 3 pints. (The above fluid measures are Imperial). Dissolve half the sulphate in half the boiling water, and gradually add the sulphuric acid; boil; add the nitric acid by degrees, boiling the liquid after each addition briskly for a few minutes. Dissolve the rest of the sulphate in the remainder of the boiling water; mix the two solutions thoroughly, and immediately add the ammonia in a full stream, briskly stirring the mixture at the same time. Collect the black powder on a calico-filter; wash it with water till the water is scarcely precipitated by a solution of nitrate of barium and dry it at a temperature not exceeding 82.2°C . (180°F .) (*Ed.*)

Black oxide of iron thus prepared forms a jet-black, or grayish-black mass, with a velvety appearance, and is attracted by the magnet. It is odorless and tasteless, dissolves in hydrochloric acid without effervescence and without a residue, from which yellowish solution it is precipitated by ammonia. Its hydrochloric solution gives the blue coloration with both ferro- and ferricyanides of potassium. It is converted by strong heat into red ferric oxide. The scales (*ferri squame*), which are struck from red-hot iron by the blacksmith's hammer, the *Ethiops martis* of the old *Materia Medica*, consist of chemical combinations of the ferrous oxide and ferric oxide in variable proportions. They are prepared for medicinal use by washing them, freeing them from impurities by the magnet; triturating them, and separating the fine powder by the method directed for making prepared chalk. It is, however, inferior in medicinal virtue to the black oxide as prepared above. *Magnetic iron ore* (magnetic oxide) consists of ferric and ferrous oxides in molecular proportions. This is an excellent iron tonic, is not changeable when exposed to the atmosphere and dampness, is more readily soluble in the fluids of the stomach than the sesquioxide, and produces no local irritation. Dose, 5 to 20 grains.

FERRI OXIDUM RUBRUM, Ferric oxide (Fe_2O_3). Molecular weight: 159.68. *Ferri peroxydum, Ferri sesquioxidium, Peroxide of iron, Sesquioxide of iron, Caput mortuum, Crocus martis adstringens, Colcothar.*—Expose sulphate of iron to heat, until the water of crystallization is expelled. Then roast it by an intense fire so long as acid vapors arise. Wash the ferric oxide until the washings, when examined by litmus, appear free from acid. Lastly, dry it on bibulous paper (*Dub.*). In this process the water and sulphuric acid of the crystallized sulphate of iron are expelled: the iron is oxidized by the oxygen of the air and partly at the expense of a portion of the sulphuric acid, which is thereby reduced to sulphurous acid. M. A. Vogel recommends the following as a preferable method of preparing a red oxide of iron or colcothar, for polishing glass and metals, without any previous washing. Into a solution of sulphate of iron made with boiling water and filtered, a concentrated solution of oxalic acid is poured, until the yel-

low precipitate of oxalate of iron is no longer formed. When the liquor has entirely cooled and ceased to deposit, the precipitate is washed on a cloth with hot water until the water ceases to acquire an acid reaction. The oxalate of iron, not yet perfectly dry, is in the next place heated on a plate of iron over a charcoal fire or lamp. The decomposition of the salt commences at about 204.4°C . (400°F .), and at a temperature a little higher than this the red oxide of iron is formed in a very finely divided state.

Red oxide of iron is an odorless and tasteless, dark, crimson-red powder, not magnetic, insoluble in water, dissolved, but not readily, by hydrochloric acid without any gas being evolved, and forming a golden-yellow solution, which is not changed to blue by ferricyanide of potassium unless ferrous oxide is present. It is anhydrous, and has been called *Colcothar* and *Crocus martis adstringens*. This compound exists native mainly in the form of *hematite*, or *red hematite*. It is but little employed as a medicine at the present day, but is largely consumed in the arts. Colcothar in finely divided state, is used as a polishing powder for glass and metals under the name *polishing rouge*, or *polirouge*. The iron paints known as *Venetian*, *English*, and *Berlin reds*, are chiefly composed of ferric oxide. Peroxide of iron possesses tonic and somewhat styptic properties, and is used principally in *strumous* and *neuralgic affections*, in combination with extract of conium. The dose is from 2 to 8 grains, 3 or 4 times a day. It may also be used in the preparation of iron plaster.

STYPTIC POWDER.—The red or styptic powder is prepared by merely submitting sulphate of iron 2 parts, and alum 1 part, to a red heat, and continuing it until a reddish substance is formed; it undoubtedly contains a portion of acid. It is powerfully astringent and styptic, and is used as an application to *bleeding piles* and *external hemorrhages*; it is usually applied in the form of ointment, but may also be given internally for the same purposes.

OCRES.—These are natural mixtures of calcareous or argillaceous earths and oxides of iron and manganese in variable proportions. They appear in commerce in powder or masses (stone ochres). Their colors largely depend upon the quantity of iron present, and upon its degree of oxidation. Occasionally heat is employed to modify the color. The chief ochres are *yellow ochre*, *red ochre*, *brown ochre*, *Spanish brown*, *Indian red*, *French ochre* (yellow), *Roman ochre*, (brown-yellow becoming purple-red when heated), and *Oxford ochre* (brownish-yellow less intense than that of Roman ochre).

INDIAN RED, Red ochre.—From Isle of Ormus, in the Persian Gulf. A purple-red pigment whose color is due to the presence of ferric oxide.

UMBER, Terra umbræ.—Klaproth states that 100 parts of this mineral contain the following substances: Alumina (5), silica (13), manganese (20), ferric oxide (48), water (14). The commercial variety, which is called *raw umber*, comes from the island of Cyprus. Umber is light, fine, and dense in texture, dry, and has a rich, light-brown color. When rubbed with the finger nail it assumes a gloss. Burning changes it to the beautiful and distinctive deep-brown known as the color of *burnt umber*. Both this and *raw umber* are much used in painting.

FERRUM OXIDATUM SACCHARATUM, Ferric saccharate, Saccharated oxide of iron, Saccharated iron.—Add gradually, with stirring, a solution of sodium carbonate (26 parts), in water (150 parts), to a mixture of solution of ferric chloride, sp. gr. 1.281 (30 parts), and water (150 parts), until complete precipitation has taken place. Wash the salt by repeated decantations with water, until it no longer gives evidence of chlorides, then drain the precipitate on muslin and squeeze it. Now add to the residue powdered sugar (50 parts), and solution of soda, sp. gr. 1.70 (5 parts), and heat the mixture on a steam-bath to complete solution. Dry by evaporation, and powder the salt, and finally add enough powdered sugar to produce 100 parts, by weight, of ferric saccharate. This salt is official in the *German Pharmacopæia*. It forms a red-brown powder; its taste is mildly ferruginous and sweet. Distilled water completely dissolves it, forming a feebly alkaline, red-brown solution. This solution, unless hydrochloric acid be present, is unaffected by potassium ferrocyanide. Hydrochloric acid, however, causes at first a dirty-green coloration, followed by the gradual formation of a deep-blue precipitate. This compound contains about 3 per cent of iron. It enters into a syrup, also official in the *German Pharmacopæia*, the *SYRUPUS FERRI OXYDATI*, or *Syrup of soluble ferric oxide*, made by mixing equal parts of distilled water, saccharated iron, and simple syrup. This contains, therefore, 1 per cent of metallic iron, and is of a deep red-brown color. Upon the statement of Köhler of Halle, saccharated oxide of iron seems to be of importance in *poisoning by arsenous acid* (arsenic). Köhler prefers it to other antidotes for this poison.

FERRI SUBCARBONAS, Subcarbonate of iron, Crocus martis aperiens, Crocus martis aperitivus, Precipitated carbonate of iron, Red oxide of iron, Sesquioxide of iron, Aperitive saffron of Mars.—It is prepared by double decomposition: Take of sulphate of iron, 4 pounds; carbonate of sodium, 4 pounds and 2 ounces; boiling water, 6 gallons (Imp.). Dissolve the sulphate and carbonate separately, each in 3 gallons of water. Mix the solutions together while yet hot, and then let the precipitate subside. Pour off the supernatant liquor, wash the precipitate repeatedly with water, and dry it (*Lond.*).

This process is about the same as that of the *U. S. P.* of 1870, which directed sulphate of iron, 8 ounces; sodium carbonate, 9 ounces, and water, 8 pints. The salt is to be prepared without heat being employed. By exposure to the air during the washing and drying, the ferrous carbonate is converted into ferric oxide by the action of the oxygen of the atmosphere, while carbon dioxide is disengaged. It usually contains a small portion of undecomposed ferrous carbonate, and is known by the name subcarbonate of iron, which distinguishes it from the ferric oxide of the preceding article. It should not be exposed to a red heat for the purpose of improving its red color, as it becomes changed in its character as well as in its medicinal efficacy. When dried at the temperature of the air it is mainly the oxyhydrate ($\text{Fe}_2\text{O}_3 \cdot \text{Fe}_2(\text{OH})_2$). Commercial subcarbonate of iron is a brownish-red powder, of a somewhat astringent taste,

odorless, not magnetic, and not dissolved by water. It is soluble in hydrochloric acid, with feeble effervescence, which solution affords a deep-blue precipitate with the ferrocyanide of potassium, a purplish-black precipitate with tincture of nut-galls, a brownish-red precipitate with the alkalis, and a red color with sulphocyanic or meconic acid. It also gives a blue precipitate with ferri-cyanide of potassium, thus showing the difference between this compound and ferric hydroxide. If it contain copper, that metal will be deposited on a bright rod of iron dipped into the above solution. After the ferric oxide has been thrown down by ammonia from the hydrochloric solution, the supernatant liquor should give no indication of any other metal in solution when chloride of barium, ferrocyanide of potassium, or hydrogen sulphide are added. In large doses it is apt to occasion nausea, with a heavy sensation in the epigastric region, and other dyspeptic symptoms; it also renders the stools black. It is an excellent chalybeate tonic and alterative, and has been successfully used in *chorea*, *neuralgia*, *chlorosis*, and *anemia*. Sometimes used in *intermittent fever*, when connected with an anemic condition, or where the nutritive functions are deranged. In *chronic diarrhœa* and *dysentery*, *enlargement of the liver and spleen*, *epilepsy*, *dropsy*, *cancer*, *scrofula*, and *diseases of the urinary organs* connected with debility, it has been successfully used. The dose is from 5 grains to 2 drachms, 3 times a day; there is, however, no necessity for large doses of any of the chalybeates, as the system can take up but a small portion daily of any of the iron compounds.

FERRI OXIDUM HYDRATUM CUM MAGNESIA (U. S. P.)—FERRIC HYDRATE WITH MAGNESIA.

SYNONYMS: *Arsenic antidote*, *Antidotum arsenici*.

Preparation.—"Solution of ferric sulphate, fifty cubic centimeters (50 Cc.) [1 fl̄, 332 M]; magnesia, ten grammes (10 Gm.) [154 grs.]; water, a sufficient quantity. Mix the solution of ferric sulphate with one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M] of water, and keep the liquid in a large, well-stoppered bottle. Rub the magnesia with cold water to a smooth and thin mixture, transfer this to a bottle capable of holding about one thousand cubic centimeters (1000 Cc.) [33 fl̄, 391 M], and fill it with water to about three-fourths of its capacity. When the preparation is wanted for use, shake the magnesia mixture to a homogeneous, thin magma, gradually add to it the iron solution, and shake them together until a uniform, smooth mixture results.

Note.—"The diluted solution of ferric sulphate, and the mixture of magnesia with water, should always be kept on hand, ready for immediate use"—(U. S. P.).

This preparation, intended as an antidote to arsenic, is a mixture of ferric hydroxide, magnesium hydroxide, and magnesium sulphate. It should be freshly prepared so that the ferric hydroxide will be in its most efficient condition, and not impaired, as is certain to be the case if the preparation be kept for a length of time. It is not necessary to separate the liquid from this preparation, as none of the ingredients are in any way caustic or objectionable, the magnesium sulphate present being desirable as a cathartic to carry off by the bowels such portions of the insoluble arsenical compound as may not be ejected in the act of emesis, or removed by the stomach-pump. As an excess of magnesia is used in preparing it, acidity is avoided.

Action, Medical Uses, and Dosage.—Antidote to *arsenical poisoning*. It should be administered like the ferric hydroxide. The magnesia itself is somewhat antidotal to arsenous acid, beside acting as a cathartic.

FERRI PHOSPHAS SOLUBILIS (U. S. P.)—SOLUBLE FERRIC PHOSPHATE.

SYNONYMS: *Ferri phosphas of U. S. P.* (1880), *Soluble phosphate of iron*, *Sodio-ferric citro-phosphate*, *Ferri et sodii citro-phosphas*, *Ferrum phosphoricum cum natrio citrico*.

Preparation.—"Ferric citrate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; sodium phosphate, uneffloresced, fifty-five grammes (55 Gm.) [1 oz. av., 411 grs.]; distilled water, one hundred cubic centimeters (100 Cc.) [3 fl̄, 183 M]. Dissolve the ferric citrate in the distilled water by heating on a water-bath. To this solution add the sodium phosphate, and stir constantly until it is dissolved. Evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of thick syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in dark amber-colored, well-stoppered bottles"—(U. S. P.).

This modern salt was at first called *Ferri Phosphas*, but the Pharmacopœial Committee of 1890 very properly designated it as *Soluble ferric phosphate*, thus preventing it from being confounded with *True ferric phosphate*. It is a different preparation from that of former pharmacopœias and of the *British Pharmacopœia*, which is an amorphous, slate-blue powder, and contains at least 47 per cent of ferrous phosphate ($\text{Fe}_2[\text{PO}_4]_2 \cdot 8\text{H}_2\text{O}$), together with ferric phosphate and some oxide. The present *U. S. P.* salt, on the other hand, is in the form of bright-green scales, and is probably a *sodio-ferric citro-phosphate*, the formula for which is not given. The British preparation is insoluble in water, while that of the *U. S. P.* is soluble. To insure the scales from turning white by age, a perfectly uneffloresced sodium phosphate must be employed, as directed in the above formula.

Description and Tests.—"Thin, bright-green, transparent scales, without odor, and having an acidulous, slightly saline taste. The salt is permanent in dry air when excluded from light, but becomes dark and discolored on exposure to light. Freely and completely soluble in water, but insoluble in alcohol. The aqueous solution of the salt has a slightly acid reaction. With potassium ferrocyanide T.S. the solution gives a blue color, but does not yield a blue precipitate, unless it has been acidulated with hydrochloric acid. If 1 Gm. of the salt be boiled with 10 Cc. of potassium or sodium hydrate T.S., a reddish-brown precipitate will be produced, and if the colorless filtrate from this precipitate be strongly acidulated with hydrochloric acid, then magnesia mixture added, and subsequently a slight excess of ammonia water, an abundant, white crystalline precipitate will be produced. If a portion of the filtrate from this precipitate be acidulated with acetic acid, and heated to boiling, no further precipitate should be produced (absence of pyrophosphate). If 0.56 (0.5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 Cc.) in 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for $\frac{1}{2}$ hour at a temperature of 40°C . (104°F .), then cooled, and mixed with a few drops of starch T.S., it should require about 12 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 1 per cent of metallic iron)"—(*U. S. P.*).

Action, Medical Uses, and Dosage.—This salt has uses similar to those enumerated below under *Ferri Phosphas*. Dose, 5 to 10 grains. Ferric phosphate is one of the special sedatives of the Schuessler system of therapy, and is used in the beginning of *febrile* and *inflammatory troubles* before exudations occur. It is employed by some practitioners where a persistent high temperature exists in threatened structural disease, and in those lingering febrile states which tend to chronicity, or where there is great adynamia with fever (Webster). *Salpingitis*, *pelvic cellulitis*, and *scleroses of the liver*, all in the early stage, are treated with this remedy and potassium chloride in alternation, to check the inflammatory process. R Ferric phosphate, 3 x trit., grains v, aqua fl̄iv. Mix. Dose, teaspoonful every hour.

Related Compounds.—FERRI PHOSPHAS, Phosphate of iron, Ferroso-ferric phosphate, Phosphas-ferroso-ferricus, Ferrum phosphoricum. The *British Pharmacopœia* directs that ferrous sulphate (3 ounces, Imp., or 80 grammes) and phosphate of sodium (2½ ounces, Imp., or 55 grammes) be each dissolved in boiling distilled water (30 ounces, or 600 cubic centimeters). Cool the solutions to between 37.8° and 54.4°C . (100° and 130°F .). Add the solution of sodium salt to the solution of iron salt, at the same time adding a little of solution of sodium bicarbonate (½ ounce, Imp., or 15 grammes, in a little distilled water). Thoroughly mix the solutions, filter through calico, wash the precipitate with hot distilled water until the filtrate gives no precipitate with barium chloride, and dry at a temperature not above 48.9°C . (120°F .).

When solutions of ordinary phosphate of sodium and sulphate of iron are brought together, a white precipitate is formed, which, so long as the sulphate of iron is in excess, is a hydrated tribasic phosphate of iron of the composition $\text{Fe}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$. This precipitate acquires, almost directly after its formation, a bluish-gray shade which, by washing, becomes somewhat stronger. When exposed to the air the precipitate becomes, as it dries, blue throughout.

Ferrous phosphate is a beautiful lavender-blue, odorless and tasteless powder. When exposed to a moderate warmth it instantly loses its blue color, becoming a greenish-gray; more strongly heated, the water is given off, the ferrous converted into a ferric salt, and the residue becomes grayish-brown. It is not dissolved by water, but dissolves in acids. Hydrochloric acid forms a greenish-yellow solution with it; in this solution ferricyanide of potassium readily detects the ferrous oxide by its blue precipitate, and sulphocyanide of potassium

the ferric oxide, by its blood-red color. If the hydrochloric solution is thrown down by excess of ammonia, the supernatant liquid must be colorless; a blue color would denote copper (Witt.).

Phosphate of iron is a valuable chalybeate tonic. It has been recommended as a remedy in cancer, to be used internally, and also applied to the diseased part; likewise to restore and invigorate the virile powers. Marked advantage has been derived from its use in *febrile diseases*. The dose is from 1 to 10 grains, 3 times a day. Dr. Routh has met with much success in some cases of *anemia* and *debility*, brought on by venereal or other excesses, over-study, and depressing diseases, by the use of another preparation of phosphate of iron, a *superphosphate*, which he has found better adapted for a speedy cure than other preparations of iron. It has likewise been of much benefit in cases of *virile weakness from onanism*, or other causes. It is prepared by adding as much phosphate of iron as the metaphosphoric acid (HPO_3), in a boiling state, would take up, and allowing it to cool. The proportions will be found nearly 2 of acid to 1 of the phosphate. The solution obtained is of a semi-transparent, greenish or slaty hue, which hardens on exposure to the air for a day; but mixed with liquorice powder or flour, it can be at once made up into pills. The compound is soluble in any proportion of water, and free from any nauseous, inky taste. Whether it is a superphosphate of iron, or the mere solution of the phosphate in the acid, remains yet to be determined. It does not gripe nor constipate, and has proved beneficial in cases of debility, where there is a prevalence of nervous symptoms, or a large quantity of phosphates voided by urine. Dose, 1 or 2 grains, 3 times a day—in some instances combined with an equal proportion of phosphate of quinine.

FERRI PHOSPHAS ALBUS, *Ferric phosphate*, *White phosphate of iron*.—Formula: $\text{Fe}_2(\text{PO}_4)_3 \cdot 4\text{H}_2\text{O}$. Molecular Weight: 373.8. If solution of ferric phosphate (4 ounces) be mixed with solution of sodium acetate (1 ounce), and sodium phosphate in solution be added, ferric phosphate precipitates as a white salt. When washed and dried at 100°C . (212°F .) a white, or yellow-white and tasteless powder results. Mineral acids (diluted), tartaric, and citric acids, as well as alkali citrates readily dissolve it, the latter giving green solutions. Alkalies decompose it.

MIXT. OF IRON (*Lac ferri*).—This is a mixture of the freshly prepared ferric phosphate in water, the mixture containing from 1 to 1.2 per cent of the salt.

The following formula appeared in the first edition of the *National Formulary*:

FERRI PHOSPHAS EFFERVESCENS (N. F.), *Effervescent phosphate of iron*.—"Phosphate of iron (U. S. P., 1880), 40 parts; bicarbonate of sodium, 600 parts; tartaric acid, 540 parts; sugar, in very fine powder, 620 parts. Triturate the ingredients, previously well dried, to a fine, uniform powder. If the compound is required in form of a granular powder, mix it with alcohol to a soft paste, and rub this through a No. 20 tinned-iron sieve or enamelled colander. Then dry it, and reduce it to a coarse, granular powder. Ninety (90) grains (or about a heaped teaspoonful) of the above compound, represents 2 grains of phosphate of iron"—(*Nat. Form.*, first edition).

FERRI PYROPHOSPHAS SOLUBILIS (U. S. P.)—SOLUBLE FERRIC PYROPHOSPHATE.

SYNONYMS: *Ferri pyrophosphas of U. S. P.* (1880), *Pyrophosphate of iron with sodium citrate*, *Sodio-ferric citro-pyrophosphate*, *Ferrum pyrophosphoricum cum sodio citrico*, *Ferri et sodii citro-pyrophosphas*, *Pyrophosphas ferricus cum citrate sodico*.

Preparation.—"Ferric citrate, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; sodium pyrophosphate, uneffloresced, fifty grammes (50 Gm.) [1 oz. av., 334 grs.]; distilled water, one hundred cubic centimeters (100 Cc.) [3 fl. 3, 183 m]. Dissolve the ferric citrate in the distilled water, by heating on a water-bath. To this solution add the sodium pyrophosphate, and stir constantly, until it is dissolved. Evaporate the solution, on a water-bath, at a temperature not exceeding 60°C . (140°F .), to the consistence of thick syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in dark amber-colored, well-stoppered bottles"—(*U. S. P.*).

Ammonium citrate was formerly used in the preparation of this compound. (For Dr. E. R. Squibb's process, employing the ammonium salt, see King's *American Dispensatory*, 15th ed., p. 1028). Owing to the fact that true ferric pyrophosphate ($\text{Fe}_2[\text{P}_2\text{O}_7]$) is not soluble in water, the U. S. P. has wisely changed the name of this compound from Pyrophosphate of Iron to *Soluble Ferric Pyrophosphate*. Soluble pyrophosphate of iron is thought to be composed of sodio-ferric citrate, sodio-ferric pyrophosphate, and ferric citrate in an uncombined condition.

Description and Tests.—The U. S. P. describes this salt as follows: "Thin, apple-green, transparent scales, without odor, and having an acidulous, slightly saline taste. The salt is permanent in dry air, when excluded from light, but becomes dark and discolored on exposure to light. Freely and completely soluble in water, but insoluble in alcohol. The aqueous solution of the salt has a

slightly acid reaction. With potassium ferrocyanide T.S. it gives a blue color, but does not yield a blue precipitate, unless it has been acidulated with hydrochloric acid. If 1 Gm. of the salt be boiled with 10 Cc. of potassium or sodium hydrate T.S., a reddish-brown precipitate will be produced, and if the colorless filtrate from this precipitate be strongly acidulated with hydrochloric acid, then magnesia mixture added, and subsequently a slight excess of ammonia water, no precipitate should be produced (distinction from and absence of ferric phosphate). If a portion of the filtrate be acidulated with acetic acid, and heated to boiling an abundant, white, flocculent precipitate (pyrophosphate) will be produced. If 0.56 (0.5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 Cc.) in 10 Cc. of water, then 10 Cc. of hydrochloric acid, and subsequently 40 Cc. of water added, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for $\frac{1}{2}$ hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require about 10 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 1 per cent of metallic iron)"—(U. S. P.).

Action, Medical Uses, and Dosage.—Pyrophosphate of iron is an excellent chalybeate tonic, and may be given in all cases where iron is indicated; from its ready solubility it may be added advantageously to many syrups and solutions. Its dose is from 2 to 5 grains, repeated 2 or 3 times a day. It appears to thoroughly influence the system, but without any unpleasant or harsh action.

Preparations.—**SYRUP OF PYROPHOSPHATE OF IRON.** This preparation may be made by dissolving 160 grains of soluble pyrophosphate of iron in 4 fluid ounces of warm water, and mixing this solution with 12 fluid ounces of simple syrup. Each tablespoonful will contain 5 grains of the salt. Owing to the tendency to mould by age, it must be prepared fresh when wanted.

LIQUOR FERRI PYROPHOSPHATIS, Solution of ferric pyrophosphate.—Ferric pyrophosphate, 120 grains; water, 5 fluid drachms. Make an aqueous solution by means of heat, filter while still hot; mix glycerin (2 fluid drachms) with the filtrate, and bring the product to the measure of 1 fluid ounce by the addition of water. This is according to Rother's method, and forms a permanent ferric pyrophosphate solution (*Drug. Circular*, 1886, p. 99).

Related Compound.—**FERRI ET SODII PYROPHOSPHAS, Natrium pyrophosphoricum ferratum, Sodio-ferric pyrophosphate.** This compound is prepared by dissolving sodium pyrophosphate (200 parts) in water (400 parts) and adding an aqueous solution of ferric chloride just short of the formation of a permanent precipitate. Mix the greenish solution thus formed with alcohol (1000 parts). The result is a white precipitate which forms a non-crystalline powder on drying, dissolving with difficulty in water. Ferric chloride added to the solution causes a precipitate of ferric pyrophosphate.

FERRI SULPHAS (U. S. P.)—FERROUS SULPHATE.

FORMULA: $\text{FeSO}_4 + 7\text{H}_2\text{O}$. **MOLECULAR WEIGHT:** 277.42.

SYNONYMS: *Sulphate of iron, Sulfas ferrous, Ferrum vitriolatum purum, Vitriolum martis purum.* When impure, *Green vitriol* and *Copperas*.

Preparation.—In a glass flask, or, on the large scale, in a leaden vessel, are mixed 6 parts of concentrated sulphuric acid with 24 parts of water, and 4 parts of pure iron (turnings or filings); the whole, frequently stirred with a porcelain or wooden spatula, is allowed to digest for 1 day; the vessel is now heated as long as any gas is evolved, then filtered, the hot filtrate mixed with $\frac{1}{2}$ part of concentrated sulphuric acid, and allowed to stand 2 days in a cool spot. The crystals which have formed, are freed from the mother liquor, and spread out on paper, if possible, in the sun to dry; then kept in a well-closed bottle or stone jar. The solution yields, on concentration, a considerable portion of salt, and from the above proportion of ingredients, 17 parts of ferrous sulphate are obtained (Wittstein).

"Concentrated sulphuric acid has no action on iron in the cold, but mixed with a certain portion of water, a lively effervescence ensues, with evolution of hydrogen gas. The free carbon of the iron separates in black flakes, while the combined carbon, at the moment of liberation, combines with hydrogen, and is given off as methane or marsh gas (CH_4), imparting to the hydrogen its unpleasant odor. If traces of phosphorus and sulphur are present, the evolved gases are not free from ill-smelling phosphide and sulphide of hydrogen."

"Ferrous sulphate should be kept in well-stoppered bottles"—(U. S. P.).

Description.—The official salt occurs in “large, pale bluish-green monoclinic prisms, without odor, and having a saline, styptic taste; efflorescent in dry air. On exposure to moist air, the crystals rapidly absorb oxygen, and become coated with brownish-yellow, basic ferric sulphate. Soluble in 1.8 parts of water at 15° C. (59° F.), and in 0.3 part of boiling water; insoluble in alcohol. When slowly heated to 115° C. (239° F.), the crystals fall to powder, and lose 38.84 per cent of their weight (6 molecules of water of crystallization)”—(U. S. P.).

A solution of sulphate of iron when exposed to the air becomes of a yellow color, and contains ferroso-ferric salt, while a yellow basic ferric salt separates. When heated, sulphate of iron fuses in its water of crystallization, leaving upon evaporation a white powder, which heated more strongly in the air absorbs oxygen and becomes red; heated gradually to redness, it evolves sulphuric acid, water, and sulphurous acid, while a dark crimson-red powder of pure ferric oxide remains.

Tests.—Any contamination of sulphate of iron by ferric sulphate may be known by the gray or greenish-yellow color of the crystals, and chemically shown by sulphocyanide of potassium, which renders its solution blood-red.

The U. S. P. directs the following tests: “The aqueous solution of the salt has an acid reaction, and, even when highly diluted, gives with potassium ferricyanide T.S. a blue color, or precipitate, and with barium chloride T.S., a white precipitate insoluble in hydrochloric acid. If 1 Gm. of the salt be dissolved in about 25 Cc. of water, the solution heated to boiling, oxidized with nitric acid, and then mixed with a slight excess of ammonia water, the filtrate from the reddish-brown precipitate should be colorless, and should not be affected by hydrogen sulphide T.S. (absence of copper, zinc, etc.). If another portion of the filtrate be evaporated to dryness, and then ignited, it should not leave more than a trace of residue (limit of salts of the fixed alkalies). If 1.39 (1.3871) Gm. of the salt be dissolved in about 25 Cc. of water, and the solution acidulated with sulphuric acid, not less than 50 Cc. of decinormal potassium permanganate V.S. should be required to impart to the liquid a permanent pink color (each cubic centimeter of the volumetric solution indicating 2 per cent of crystallized ferrous sulphate)”—(U. S. P.).

The impure sulphate of iron (copperas) met with in commerce should not be used in medicine.

Action, Medical Uses, and Dosage.—In small doses, sulphate of iron causes more or less constipation, is absorbed, and acts as a tonic, astringent, and emmenagogue; it blackens the stools. In large doses, it causes pain, heat, uneasiness at the pit of the stomach, and retchings and emesis. In excessive doses, it is an irritant poison, acting chemically on the albumen and other organic constituents of the tissues. The stomach is more or less injured by a long-continued use of it. It has been used as a tonic in *scrofula*, *dyspepsia*, *chlorosis*, *amenorrhœa*, and in *debility* following protracted diseases. In *phthisis pulmonalis* the following preparation has been found very serviceable; it relieves cough, assists expectoration, improves the appetite and digestive functions, and invigorates the whole system: Take of commercial sulphate of iron. 6 drachms; whiskey or good Holland gin, $\frac{1}{2}$ pint; mix together. The dose is $\frac{1}{2}$ fluid drachm every 2 hours. As an astringent, sulphate of iron is given in *humid asthma*, *passive hemorrhages*, *chronic mucous catarrh*, *leucorrhœa*, *gleet*, *diabetes*, *old dysenteric affections*, etc. The dose is from $\frac{1}{2}$ to 6 grains in pill form. Prof. A. J. Howe states that “a strong solution of sulphate of iron has effected cures of *diabetes*, and may sometimes be successfully employed in *dropsies* arising from various causes. A solution holding 10 grains of the sulphate to 1 fluid ounce of water, may be given in doses of from 2 to 4 fluid drachms, repeated 3 or 4 times a day. In some instances where diuretics and hydragogue cathartics have been employed without beneficial results, the sulphate of iron has produced the happiest effects.” From 1 to 10 grains of the sulphate of iron dissolved in 1 fluid ounce of boiling water has been found useful as a collyrium in *chronic ophthalmia*, a wash (or, with lard, as an ointment) in *erysipelas* and some *eczematous skin diseases*, and as an injection in *gleet* and *chronic dysentery*, *prolapse of the rectum*, etc. *Cancerous parts*, particularly of the uterus, may be washed with a solution of 1 drachm of the salt to 1 pint of water. An injection of 2 grains to 1 pint of water relieves *bleeding piles*. Applied locally the solution does good service in *chancroid*. Sulphate of iron has been used as a disinfectant, particularly in correcting foul odors from cesspools, drains, vaults,

etc. It may be used freely, either in substance or in solution, the products being sulphate of ammonium and hydrated sulphide of iron. Sulphate of iron becomes changed when in contact with the atmosphere, and which alteration may be prevented by sprinkling the crystals of this salt with alcohol, or with sweetened water, and keeping them in well-closed vessels. Mr. Welborn has succeeded in preserving them by a still more simple method, viz.: by placing a small fragment of camphor in the upper part of the vessel containing the ferrous salt. Animal tissues become mummified when taken from a solution of neutral sulphate of iron (3 per cent) in which they have been immersed for some time. A weak solution of ferrous sulphate is one of the most effective applications to *rhus poisoning*. Dose, $\frac{1}{2}$ to 6 grains, or 3 \times trit., 1 to 5 grains.

Specific Indications and Uses.—General relaxation and languor of the system; uterine inactivity; amenorrhœa. Locally, to *rhus poisoning*.

FERRI SULPHAS EXSICCATUS (U. S. P.)—DRIED FERROUS SULPHATE.

FORMULA: Approximately, $2\text{FeSO}_4 + 3\text{H}_2\text{O}$. MOLECULAR WEIGHT: 357.28.

SYNONYMS: *Ferri sulphas exsiccata*, *Dried sulphate of iron*, *Dried ferrous sulphate*.

Preparation.—"Ferrous sulphate, in coarse powder, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]. Allow the salt to effloresce at a temperature of about 40°C . (104°F .), and then heat it in a porcelain dish, on a water-bath, constantly stirring, until the product weighs from sixty-four to sixty-five grammes (64 to 65 Gm.) [2 ozs. av., 113 grs., to 2 ozs. av., 128 grs.]. Lastly, reduce the residue to a fine powder, and transfer it at once to perfectly dry, well-stoppered bottles"—(U. S. P.).

Description.—"A grayish-white powder, slowly but completely soluble in water, and conforming approximately to the reactions and tests given under *Ferri Sulphas*"—(U. S. P.). The granulated sulphate is best adapted for the preparation of the anhydrous salt. With extra care the salt may be heated to 280°C . (536°F .), without loss of the acid, at which point the last molecule of water is driven off.

Action, Medical Uses, and Dosage.—Same as sulphate of iron; to be used in pill form. Externally, in solution, as an astringent lotion for *indolent ulcers*, and as an injection in *leucorrhœa* and *gonorrhœa* of females.

FERRI SULPHAS GRANULATUS (U. S. P.)—GRANULATED FERROUS SULPHATE.

FORMULA. $\text{FeSO}_4 + 7\text{H}_2\text{O}$. MOLECULAR WEIGHT: 277.42.

SYNONYMS: *Ferri sulphas præcipitatus* (Pharm., 1880), *Ferri sulphas granulata*, *Precipitated ferrous sulphate*, *Granulated sulphate of iron*, *Precipitated sulphate of iron*.

Preparation.—"Ferrous sulphate, one hundred grammes (100 Gm.) [3 ozs. av., 231 grs.]; distilled water, one hundred cubic centimeters (100 Cc.) [3 fl. oz., 183 Ml.]; diluted sulphuric acid, five cubic centimeters (5 Cc.) [81 Ml.]; alcohol, twenty-five cubic centimeters (25 Cc.) [406 Ml.]. Dissolve the ferrous sulphate in the distilled water previously heated to boiling, add the diluted sulphuric acid, and filter the solution while hot. Evaporate the solution immediately in a tared porcelain capsule, on a sand-bath, until it weighs one hundred and fifty grammes (150 Gm.) [5 ozs. av., 127 grs.], and then cool it quickly under constant stirring. Transfer the product to a glass funnel stopped with a plug of absorbent cotton, and when it has thoroughly drained, pour upon it the alcohol. When this also has drained, spread the crystalline powder on bibulous paper, dry it quickly in the sunlight, or in a dry room, at the ordinary temperature, and transfer it at once to perfectly dry, well-stoppered bottles"—(U. S. P.).

Description.—"Granulated ferrous sulphate is a very pale, bluish-green, crystalline powder, which should conform in every respect to the reactions and tests given under *Ferri Sulphas*"—(U. S. P.). Granulated sulphate of iron does not

oxidize as readily as does the ordinary sulphate, and is preferred to that salt in making dried sulphate of iron, and also the syrup of phosphate of iron.

Action, Medical Uses, and Dosage.—Uses same as *Ferrous Sulphate*, which see.

FERRI SULPHIDUM.—FERROUS SULPHIDE.

FORMULA: FeS . **MOLECULAR WEIGHT:** 87.86.

SYNONYMS: *Sulphide of iron, Sulphuretum ferrosus, Sulphuret of iron, Ferri sulphuretum, Protosulphide of iron.*

Preparation.—Sulphide of iron may be made by heating an iron rod to a full white heat in a forge, applying a stick of sulphur to the end of the rod, and allowing the fused globules of sulphide which form to fall into a deep vessel filled with water. These should be free of sulphur and kept in a close vessel. In this process, to be successful the iron must be raised to a full white heat; at a lower temperature the sulphur is merely fused on its surface; but if the heat be high enough, the two bodies unite with the emission of brilliant sparks, when the ferrous sulphide is instantly formed, and falls in a fused and incandescent state, and, on being received in the water, brownish-yellow globules are obtained, having a somewhat crystalline texture (Wittstein). An inferior preparation may be obtained by mixing thoroughly together sublimed sulphur 1 part, and iron filings 8 parts. Heat the mixture in a covered crucible till it becomes red hot, then remove the crucible from the fire, still keeping it covered, and allow the action to go on without any further heat (*Ed.*).

Several sulphides of iron are known, but only one used in pharmacy, viz.: the ferrous sulphide. Iron and sulphur combine at a red heat to form this sulphide. The excess of sulphur vaporizes, and, coming in contact with the air, ignites to form sulphur dioxide (SO_2). Three hundred and fifty parts of iron require 200 parts of sulphur, but an excess of the latter is always necessary, as, before the combination of the two is complete, a portion has been volatilized. When made by the second process, the crucible must not be opened until quite cool, otherwise the mass absorbs oxygen with avidity, becoming partly converted into a sulphate of iron.

Description.—Sulphide of iron varies in appearance according to its mode of preparation; by the first-named process it is yellowish, by the second a dark-gray mass, heavy, full of blisters, of a partly metallic luster, odorless, and tasteless. Kept in a close vessel, it undergoes no change; exposed to the air, especially if moist, it oxidizes and acquires an inky taste. In diluted sulphuric or hydrochloric acid it must, with a powerful evolution of hydrogen sulphide gas, gradually and almost entirely dissolve (a thorough solution must not be expected on account of the carbon in the iron), and the gas must be entirely absorbed by a solution of acetate of lead, else it contains free hydrogen (Wittstein).

Uses.—Sulphide of iron is used in pharmacy and analytical chemistry for procuring HYDROGEN SULPHIDE (*Hydrosulphuric acid* or *Sulphuretted hydrogen gas*).

HYDROGEN SULPHIDE.—Formula: H_2S . Molecular Weight: 33.98. It may be prepared as follows: Diluted sulphuric or hydrochloric acid is added to sulphide of iron in a proper vessel, when the sulphuretted hydrogen is disengaged as a gas, and may be collected over warm water, or solution of salt. The reaction is represented by the following equation: $\text{FeS} + \text{H}_2\text{SO}_4 = \text{H}_2\text{S} + \text{FeSO}_4$. The excess of water in the diluted acid promotes the action by keeping in solution the salt which forms. Sulphide of hydrogen is a transparent, colorless gas having the odor of rotten eggs and a specific gravity of 1.178 to 1.19. It reddens litmus, burns in the air with a bluish flame, producing sulphurous acid gas and water, and depositing sulphur on the sides of the vessel in which it is burned. In bottles not quite full or imperfectly corked, its aqueous solution becomes milky, a white powder of sulphur is thrown down, and this can go on until the water contains no scent of the gas. This is owing to the combination of the atmospheric oxygen with the hydrogen, forming water. If the washing of this gas is omitted it may contain sulphuric acid, known by chloride of barium rendering it turbid. Water absorbs two or three times its volume of the gas, and acquires its smell and a nauseous, sweetish taste. Sulphide of hydrogen blackens white lead and solutions of the salts of lead, copper, bismuth, etc. Under a pressure of 17 atmospheres at 10°C . (50°F .), it condenses into a limpid fluid of sp. gr. 0.9, and which freezes at -85°C . (-122°F .), forming a white, crystalline, translucent substance. When respired, even although much diluted with air, it is highly deleterious, and as it is often formed where animal matters or excrements putrefy, as in burying vaults or cloacæ, it not infrequently causes the death of the workmen who suddenly come

in contact with it. When air is moderately diluted with it, respiration causes immediate insensibility with depression of all the powers of life; still more diluted, it causes convulsions, and air but slightly contaminated with it, causes nausea, debility, and headache. The smell of the gas ought, in all cases, to be viewed as a warning of danger.

From many metallic solutions hydrogen sulphide gas precipitates the metal in the form of sulphide. Upon the difference in the solubilities of these sulphides is based an analytical classification of the metals, an important subject that we can not, however, consider in detail. The gas is usually generated in the well-known Kipp's apparatus, but numerous other and simpler devices have been suggested.

Hydrogen sulphide, as it exists naturally in some mineral waters, is undoubtedly of value in *cutaneous disorders*, particularly those in which calcium sulphide is beneficial. The Bergeon method of rectal injection of hydrogen sulphide for the cure of *phthisis* proved to be injurious instead of beneficial.

FERRI VALERIANAS (U. S. P.)—FERRIC VALERIANATE.

SYNONYMS: *Valerianate of iron, Ferrum valerianicum.*

Preparation.—This compound may be made as follows: Take clean iron filings, put into a Wedgewood mortar, add gradually an equal weight of valerianic acid, and stir constantly. In an hour add distilled water; gently warm the whole in a flask and filter. The surface in contact with the air soon becomes covered with a crystalline layer of the iron valerianate; collect this on a filter, and expose as before, repeating the process as long as crystals are obtained (Ruspini). It is generally made, however, by acting upon solution of ferric chloride or ferric sulphate with solution of sodium valerianate. The following is Wittstein's method: To a solution of 3 parts of crystallized ferric chloride in 100 parts of water, add a cold solution of sodium valerianate, made by saturating 5 parts of oily valerianic acid in 60 parts of water, with sodium carbonate, and then boiling the liquid to expel all the carbon dioxide. The valerianic acid drives off the carbon dioxide from the sodium carbonate, and uniting with the base, forms a neutral salt. Fifteen hundred parts of the terhydrated valerianic acid require 1790 parts of crystallized carbonate of sodium. If this neutral solution is added in sufficient quantity (as long as it causes a precipitate), to a solution of ferric chloride, or any persalt of iron, a dark brick-red precipitate of valerianate of iron is formed, and readily soluble sulphate or chloride of sodium. Forty-five hundred parts of valerianic acid saturated with sodium carbonate require 2704 parts of crystallized ferric chloride, or 3513 parts of dry ferric sulphate. The affinity between the oxide of iron and valerianic acid is so feeble that a gentle heat will remove most of the acid; consequently, the precipitation should take place only when cold. The precipitated valerianate of iron is to be washed with a little cold water, and dried at a temperature not exceeding 20° C. (68° F.). If too much water be used, or if the washing be continued, the acid will be removed.

Its composition, which is variable, depends on the processes by which it is made.

Description and Tests.—This salt is officially described as "a dark brick-red, amorphous powder of somewhat varying chemical composition, having the odor of valerianic acid, and a mildly styptic taste; permanent in dry air. Insoluble in cold water, but readily soluble in alcohol. Boiling water decomposes it, setting free the valerianic acid, and leaving ferric hydrate. When slowly heated, the salt parts with its acid, without fusing, but, when rapidly heated, it fuses and gives off inflammable vapors having the odor of butyric acid, and, on complete ignition, leaves a residue of ferric oxide. The stronger acids decompose the salt with the liberation of valerianic acid. If 0.56 (0.5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 Cc.) in 2 Cc. of hydrochloric acid and 15 Cc. of water, and after the addition of 1 Gm. of potassium iodide the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled and mixed with a few drops of starch T.S., it should require not less than 15 nor more than 20 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color of the liquid (each cubic centimeter of the volumetric solution indicating 1 per cent of metallic iron)"—(U. S. P.).

"Ferric valerianate should be kept in small, well-stoppered bottles, in a cool and dark place"—(U. S. P.). Valerianate of iron is not extensively employed by Eclectic practitioners.

Action, Medical Uses, and Dosage.—Valerianate of iron is a nervo-tonic, and will be found serviceable in *nervous disorders, hysteria, chorea, neuralgia, chlorosis, and anemic conditions* with excitability or irritability of the nervous system. The dose is 1 or 2 grains in pill form, repeated 3 or 4 times a day.

FERRUM (U. S. P.)—IRON.

SYMBOL: Fe. **ATOMIC WEIGHT:** 55.88.

"Metallic iron in the form of fine, bright, and non-elastic wire"—(U. S. P.).

The *British Pharmacopæia* directs annealed iron wire (diameter 0.005 inch) or wire nails, both to be free from oxide. Iron filings (*Ferri Ramenta*) were directed by the U. S. P., of 1850.

Source, History, and Preparation.—No metal is of more utility to mankind, or more abundantly dispersed throughout the globe than iron. Independently of its existence in the form of ores, it is found to a greater or less extent as a constituent of earths, minerals, and organized substances. It is found in meteoric stones, and forms an essential constituent of the blood in man and many animals, and is one of those metals which, under certain circumstances, may be employed medicinally with safety and advantage to the human constitution.

Iron occurs in its native state, and in combination with other substances forming iron ores. Its most common ores are the sulphide of iron (pyrites), the oxides, such as magnetic iron ore (Fe_3O_4), red and brown hematite, micaceous, and clay iron ores; and the carbonate, phosphate, sulpharsenide, etc., of iron. A superior iron is obtained from those ores known as magnetic, red hematite, or micaceous; these are found in abundance in Sweden. Spain, France, and Germany likewise furnish the carbonate, clay iron ore, brown hematite, etc. In this country iron is procured in large quantity, principally from the magnetic, micaceous, and clay iron ores, and some of the ores, especially those of the Atlantic states, are at least equal to the best ore from Sweden.

As the character of the ores differs, the modes of procuring the iron from them will vary according to the kind of ore. Ores containing sulphur can not be used in the metallurgy of iron, only the oxides, carbonates (spathose ores), and clay iron stones being employed. The argillaceous ores and the brown hematites (hydrated ferric oxides) undergo a preliminary process of calcination by mixing them with coal and burning the mixture either in open heaps, or in properly constructed roasting furnaces. The roasted iron ore thus prepared is mixed with flux and fuel, and exposed to a strong heat in a blast furnace. The flux is generally limestone, which separates the alumina and silica; the fuel is charcoal, coke, or anthracite. The impurities which fuse with the flux are termed the *slag*, which floats above the melted iron, and flows in a constant but slow stream over the dam, on the opposite side from that where the metal is to flow. As soon as the process is perfected, the orifice through which the slag flowed is closed, the blast stopped, and the melted iron is run into molds, forming what is known as "*pig iron*," or "*cast iron*." Two varieties of cast iron exist, differing mainly in the form of the carbon present. In *white cast iron* the carbon exists as carbide of iron in combination; in *gray cast iron* most of the carbon exists free as graphite. The presence of manganese in the ore induces the formation of *white cast iron* (or *specular pig iron*), while silica has a tendency to produce *gray cast iron*.

Cast iron is used to make *malleable iron* and *steel*, both containing considerably less carbon. The proportion of carbon determines their properties. To effect the expulsion of the excess of carbon, the "*pigs*" undergo certain processes of *refining* and *puddling*, in properly constructed furnaces, in which the carbon is gradually burnt out by a free access of air and constant agitation; phosphorus and sulphur also disappear. Finally the iron is removed from the furnace, and either hammered or rolled into long flat or round pieces, forming the ordinary soft or malleable iron. Cast iron contains from 3 to 6 per cent of carbon, malleable iron only from 0.15 to 0.5 per cent, while steel stands intermediate between the two. Diminution of carbon raises the fusing point of iron. Steel can be *hardened* by dipping it red hot into cold water, subsequent annealing, often called *tempering*, being required to deprive it of its brittleness. It may be obtained by different pro-

esses, and is now manufactured in great quantities from pig iron by the *Bessemer process*, which consists in burning out the excess of carbon by means of a current of air forced through the molten pig iron contained in a specially constructed pear-shaped vessel, called the *converter*. The heat of the combustion of the carbon is sufficient to maintain the metal in a molten condition. Sheet iron with a coating of tin is known as *tin plate*; coated with zinc it is known as *galvanized iron*.

Description and Properties.—Iron has a grayish color, when pure almost silver white. Its fracture is granular, or irregularly foliaceous, with a metallic luster; when polished it has great brilliancy, which is rapidly lost under exposure to moisture and air combined. Its taste is peculiar and somewhat astringent, and it emits a peculiar smell when rubbed. It has great tenacity and ductility, and considerable malleability, but not so much as gold, silver, copper, etc. Its specific gravity is 7.788, which increases by rolling or drawing. When absolutely pure, it fuses only at a very intense heat, 1800°C . (about 3300°F .), while white pig iron fuses at about 1100°C . (2012°F .). It is attracted by the magnet. Iron wire, having a little cotton tied to its extremity, plunged into oxygen gas or into liquid air while the cotton is in flames, burns brilliantly. Damp atmosphere soon tarnishes its surface, and gradually changes it into a brown or red powder, well known under the name of rust, which is hydrated ferric oxide. Iron combines with oxygen and forms two oxides, *ferrous oxide*, *protoxide*, or *monoxide of iron* (FeO), and the *ferric oxide*, *peroxide*, or *sesquioxide of iron* (Fe_2O_3), and these united form the *black oxide* ($\text{FeO} + \text{Fe}_2\text{O}_3 = \text{Fe}_3\text{O}_4$). A *ferric acid*, or *teroxide of iron* (FeO_3), has likewise been described. It is not known free, and is very easily decomposed. Iron unites readily with sulphur, with iodine if moisture be present, with most of the metals, and with all the non-metallic elements, hydrogen perhaps included. It forms salts with the acids, which are generally soluble and crystallizable.

The salts of *ferrous oxide*, for the most part, pass into ferric oxide salts, from their absorption of oxygen. Hence, they act in some cases as reducing agents; gold is completely reduced from its solutions by sulphate of iron (*ferrous sulphate*). *Ferrous oxide* is influenced by the magnet.

Ferric oxide (*sesquioxide*, or *peroxide of iron*) (Fe_2O_3) occurs native as red hematite and specular iron ore. It is not influenced by the magnet. For its mode of preparation see under *Ferri Oxidum Hydratum*.

The native magnetic oxide of iron, or black oxide (the *loadstone*) is a heavy, black mineral, strongly attracting iron filings or steel. Its formula is Fe_3O_4 . It is formed when iron is subjected to red heat and hammered, the black scales in smith shops being an example.

Iron forms 2 lines of salts, corresponding to the two oxides named—the *higher* (*ferric*) and the *lower* (*ferrous*) salts. *Ferrous salts* are usually produced when iron is acted upon by diluted acids under exclusion of atmospheric oxygen. *Ferric salts* require for their production in addition the intervention of a strong oxidizing agent, *e.g.*, nitric acid as well as an additional amount of the acid whose salt is desired. Hydrated ferrous salts are bluish-green, or, if anhydrous, whitish. The oxalate is an exception, being yellow. Ferric salts are, as a rule, dark colored; the normal ferric salts being yellow-brown or brown if hydrated, and whitish in anhydrous state; the basic ferric salts are brown or brown-red. Hydrochloric acid dissolves such ferric salts as refuse to dissolve in water.

Tests.—“**FERROUS SALTS**, in slightly acid solution, produce white precipitates with ferrocyanide of potassium. This precipitate rapidly absorbs oxygen from the air and turns blue. Ferrous salts are prone to absorb oxygen from the air and pass into *ferric salts*, therefore the precipitate is usually of a bluish-white color from the presence of ferric salts. If the solution of a ferrous salt be mixed with a solution of ferricyanide of potassium (red prussiate of potash), a deep blue precipitate at once results, insoluble in hydrochloric acid.

“**FERRIC SALTS** form blue precipitates with ferrocyanide of potassium (yellow prussiate of potash). If the solution of ferric salt is alkaline it must be rendered acid with acetic acid, and if it contain free mineral acid, add an excess of an alkaline acetate before applying the test. Ferric salts in neutral or moderately acid solution, strike a blood-red color with potassium sulphocyanide. This test

is extremely delicate. An alkaline acetate in excess prevents the reaction." Tincture of galls or solutions of tannin produce with iron salts a black precipitate of tannate of iron.

Action, Medical Uses, and Dosage.—Iron in its metallic form has no action on the system; when swallowed in this state it becomes oxidized, apparently at the expense of the water in the stomach, for eructations take place, having a disagreeable chalybeate taste, and an odor of hydrogen. It was formerly usually given in the form of iron filings, in doses of from 5 to 10 grains. Now, when metallic iron is desired, reduced iron, in doses of from 1 to 5 grains, is usually selected. The proper method of obtaining iron filings for medicinal purposes, is to take a piece of soft, malleable, pure iron, and file it down; those obtained from the blacksmith's workshop, whether cleansed by the magnet or not, are impure and not fit for internal administration. Iron wire is generally sufficiently pure for the preparation of filings.

The various ferruginous preparations are termed chalybeate tonics; most of them also possess astringent properties. When taken for some time in small doses, they have the property of strengthening and sometimes accelerating the pulse, improving digestion, exciting the functions of the various organs, and augmenting the number of the red or coloring particles of the blood. When administered internally, iron probably enters the blood, as, after its exhibition, it has been detected in the urine, milk, and blood. Whether it increases the iron of the blood, is still an unsettled question, although it renders that fluid more florid. When iron has been taken to too great an extent, it produces more or less thirst, pain in the head or a sense of fullness, increased heat of the body, dizziness, laborious respiration, distension of the limbs, and other manifestations of vascular excitement. The indications for the use of the preparations of iron are "debility, feebleness, and inertia of the different organs of the body, atony (marked by a soft, lax, flabby condition of the solids), and defect of the red corpuscles of the blood—as where there is a general deficiency of this fluid (*anemia*, *oligæmia*) or a watery condition of it (*hydræmia*, *serous crasis*, *leucophlegmatic temperament*)" (P.).

These indications of Pereira, perhaps, can not be improved upon at the present time. Prof. Scudder regarded the deep, solid, blue discoloration of the mucous tissues and tongue, the coloring sometimes deepening to purplish, as the best indication for iron and its salts. Probably *anemia* is one of the best indications for iron, especially where the supply of red corpuscles is gradually and permanently diminished. If the loss is due to hemorrhages or other debilitating effects, and the digestive function is in good operation, food would probably be more beneficial than iron; but when the digestion and assimilation are impaired, iron becomes a most important remedy. Not only does it increase the number of red discs, but causes them, when pallid and shrunken, to become florid and plump; their oxygen-carrying powers are increased and better assimilation and nutrition is the result. On the other hand, in *anemia*, after the proper number and condition of red discs have been attained, its further administration becomes harmful, and, while iron is an important factor in the treatment of this condition, it must not be forgotten that it should constitute only a part of the treatment, and that proper food and hygienic measures should go hand in hand with its administration. Some contend for, and it has been the custom for years to give iron in enormous doses. Inasmuch as but a very little iron can be assimilated and elaborated in the blood, it would appear that the smaller doses would be less apt to provoke gastro-intestinal irritation, thus favoring their absorption. For this reason many prefer the small and even the minute dose, for all excess over that which is elaborated is discharged in the feces, and undoubtedly large doses harm by provoking constipation and other effects not calculated to improve digestion and assimilation. Eclectic physicians, as a rule, have favored the small doses. When iron is not assimilated and when provocative of gastric disorders, it does harm, and this is particularly the case in certain *nervous disorders* and particularly in *epilepsy*. In nervous disorders, it should not be employed unless there is clearly an impoverished condition of the blood. Iron and its compounds are, of course, only palliative in structural diseases, as *cancer*, *interstitial nephritis*, *tuberculosis*, etc. *Active hemorrhage*, as a rule, contraindicates the use of iron. *Menorrhagia*,

however, when profuse and watery, is benefited by it, as well as cases of scanty menses with a pale flow. In both instances the blood is lacking in red discs. *Passive hemorrhages*, on the contrary, are well treated with iron salts, particularly those made astringent by their union with the acidulous radical of the mineral acids. Iron is of value in *malarial disorders*, only in those cases in which the trouble has lasted long enough to induce a marked impoverishment of the blood itself. Ferrocyanide of iron, however, is thought by some to have some antidotal power over *malaria*. Iron is, therefore, applicable where the blood is poor in quality through a deficiency of its red corpuscles, and when associated with this there is marked debility, nervous depression, exhaustive discharges, and feeble digestion. Bearing in mind the indications, it is useful in the following disorders in which its salts have been efficiently employed: *Chorea, hypertrophy of the spleen, neuralgia, uterine debility, scrofula, leucorrhœa, rachitis, anemic and chlorotic conditions, chronic discharges from enfeebled and relaxed mucous tissues, chronic paralysis, atonic dyspepsia, albuminuria, desquamative nephritis, diabetes, etc.* The therapeutical influence of the several medicinal salts of iron are nearly the same, but where they become improved or qualified by union with other agents, reference will be made thereto under their respective captions. As a rule, in *erysipelas* the tincture of the chloride is preferred; the iodide is preferred as an alterative; the salicylate in fetid intestinal discharges; the phosphate in nervous depression; in excessive anemia the stronger preparations like the chloride, sulphate, and acid solution of iron; in ordinary debility the ammonio-citrate, citrate of iron and potassium, or the pyrophosphate, etc., are usually selected. When iron is in the form of ferrous oxide it is generally more active than where it is present as a ferric oxide. The preparations of iron are contraindicated in fever, acute inflammation, congestion of important organs, active hemorrhages, intestinal irritation, in persons subject to determinations of blood to the head, or affected with habitual constipation. The various salts and their doses will be given under their respective heads. The dose of reduced iron is from 1 to 5 grains; of iron filings, 1 to 10 grains.

Specific Indications and Uses.—Anemia, with debility, solid bluish color of the membranes and tongue; muscular relaxation.

Iron Salts.—**FERRI SALICYLAS, Ferrous salicylate.** Make solutions by dissolving ferrous sulphate (100 parts) in boiling water (200 parts), and of sodium carbonate (110 parts) in boiling water (200 parts). Filter the separate solutions, and, when cold, mix them together. Wash the resultant precipitate by decantation until all the sulphate of sodium is separated. Place the magma in a porcelain vessel and suspend the carbonate in water, and then dissolve it by the addition of salicylic acid, gently heating the mixture to facilitate solution. Filter, place on a water-bath, and dry by evaporation. This salt possesses properties more akin to those of salicylic acid than to iron. It is claimed to be the most efficient iron salt for hypoderdermatic use. Internally, it has been given in the *fetid diarrhœa of infants, acute rheumatism of the joints, aphthæ, erysipelas, and diphtheria*. It is regarded as a sedative, febrifuge, and diaphoretic.

FERRI ALBUMINAS, Ferric albuminate, Albuminate of iron.—Prof. C. Lewis Diehl's process for the preparation of this compound (see *Amer. Jour. Pharm.*, 1880, p. 177-190), is essentially as follows: Mix 10 troy ounces of egg albumen with its bulk of water, and make another solution of 125 minims of official ferric chloride solution diluted with 10 fluid ounces of water. Mix the solutions and filter. To the filtrate add 10 fluid ounces of saturated solution of chloride of sodium, put the resultant precipitate on a wet muslin strainer, and wash it with a mixture of sodium chloride in saturated aqueous solution (salt, 1 part, and water, 3 parts) until but a feeble iron reaction results in the filtrate. Drain the magma dry as nearly as possible by strong pressure, and complete the drying by atmospheric exposure. Finally, powder the product. This process gives a cinnamon-brown powder, which dissolves in water, especially if the latter be made slightly acid with hydrochloric acid. Owing to the fact that a little sodium chloride is present, the otherwise tasteless albuminate has a slight taste of common table salt. This salt is preferred by many on account of its rapid absorption, as a remedy for *anemia and chlorosis*. It may be administered alone or in combination in pill, but the best method is to administer a freshly prepared solution of 20 to 25 or 30 grains in water. *Gastric ulcer, irritative stomach disorders*, and the complications of the *menopause*, all in anemic persons, have been successfully treated with it.

FERRI ET MAGNESII CITRAS, Iron and magnesium citrate.—Dissolve freshly prepared ferric hydroxide, 2 ounces, in a moderately hot solution of citric acid, 3 ounces. Then saturate the foregoing liquid with magnesium carbonate. Filter, evaporate on a water-bath to a syrupy state, dry, and scale from glass. This salt forms transparent, soluble, greenish-yellow scales, having a faintly acid and feebly ferruginous taste. Alcohol and ether do not dissolve it. The dose ranges from 5 to 10 grains.

FERRI ET BISMUTHI CITRAS, Iron and bismuth citrate.—This compound is not a definite salt, and is prepared by adding ferric ammonio-citrate to citrate of bismuth dissolved in an ammoniacal aqueous solution. It has been used in *dyspeptic disorders*.

FERRI TANNAS, Ferric tannate, Tannate of iron.—Ferric tannate may be produced as a bluish or greenish-black precipitate by treating cold ferric solutions with solution of tannin; also, by exposing to the atmosphere a mixture of tannin and a ferrous compound. The composition of tannate of iron varies somewhat according to the conditions observed in its preparation. Concentrated organic and the mineral acids decompose it, while boiling in water reduces it to a ferrous salt. Tannate of iron possesses tonic and astringent properties. It has been used with benefit in *chlorosis*, *amenorrhœa*, *chronic diarrhœa*, and in the *diarrhœa* accompanying some *febrile diseases*, etc. The dose is 2 or 3 grains made into pills, and gradually increased, so that in the course of a day 30 grains may be given. Tannate of iron does not stain the teeth.

FERRI OXALAS, Ferrous oxalate ($\text{FeC}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$).—Molecular weight: 179.58. The U. S. P. of 1870 prepared this salt by mixing solution of ferrous sulphate (2 ounces of salt) and oxalic acid (436 grains). "When a solution of ferric hydroxide in aqueous oxalic acid is exposed to the action of sunlight, carbon dioxide is evolved, and the ferrous salt is precipitated in fine lemon-colored glistening crystals (Roscoe and Schorlemmer). It is nearly tasteless, odorless and permanent, being but sparingly soluble in water (cold or hot), but dissolving in warm diluted sulphuric acid, and in cold hydrochloric acid. It is regarded by some (Hayem), as the best of the chalybeates; while others consider it a feeble agent. The dose is from 2 to 3 grains.

FERRI BENZOAS, Ferric benzoate ($\text{Fe}_2[\text{C}_6\text{H}_5\text{O}_2]_3 \cdot 6\text{H}_2\text{O}$).—Molecular Weight: 945.8. Precipitate ferric sulphate solution with a strong solution of either ammonium or sodium benzoate. Wash the precipitate on a filter with a small portion of cold water, press the salt, and dry it. This forms an almost tasteless brown-orange powder, which, when heated to 135°C . (275°F .), loses water and becomes brown. The salt is decomposed at a higher heat, benzoic acid subliming. Alcohol and water partially dissolve it, the undissolved residue being basic ferric benzoate. This agent is employed where the action of benzoic acid with iron is desired. Dose, 3 to 5 grains.

FERRI MALAS, Ferrous malate, Extractum ferri pomatum.—Digest for several days iron filings (3 or 4 per cent) with expressed sour-apple juice, at an elevated temperature. After reaction is complete, filter and evaporate. A variable amount of iron is present in this preparation which is quite popular in Europe. The *German Pharmacopœia* recognizes a *Tinctura ferri pomata* consisting of the blackish-green ferrous malate 1 part, made into solution with cinnamon water (containing alcohol $\frac{1}{3}$ part by weight) 9 parts. Ferrous malate prepared as above, is, of course, not a definite preparation. It is mildly chalybeate, and does not color the teeth. The dose of the salt is 4 or 5 grains; of the tincture from 20 to 60 drops.

FERRI STEARAS, Stearate of iron.—Is made by dissolving separately, in about three times their weight of water, 1 part of sulphate of iron, and 2 parts of hard soap, and then mixing the solutions; the resulting greenish precipitate is to be separated, dried, melted by a gentle heat, spread on cloth, and used like an ordinary plaster.

FERRI SUCCINAS ($[\text{C}_4\text{H}_4\text{O}_4]_2\text{Fe}_2[\text{OH}]_2$), *Succinate of iron, Succinate of peroxide of iron.*—Take of succinate of ammonium, 1 ounce; solution of ferric sulphate, 2 ounces; distilled water, a sufficient quantity. Dilute the solution of tersulphate of iron with 8 ounces of the distilled water, and having dissolved the succinate of ammonium in 4 ounces of the distilled water, warm the solutions and mix them together, continuing the heat moderately (not to exceed 78.6°C . [170°F .]), until the succinate of iron is completely precipitated. Wash the precipitate with distilled water until the washings will no longer give a precipitate with chloride of barium and aqua ammoniæ, and keep the hydrate under water in a stoppered bottle. The succinate of ammonium employed herein is prepared as follows: Take of aqua ammoniæ, sp. gr. 0.980, 1 fluid ounce; succinic acid, $\frac{1}{2}$ fluid ounce. By the aid of a gentle heat dissolve the succinic acid in the ammonia water; then evaporate the solution sufficiently (very little), and set it aside to crystallize.

Prof. W. T. Wenzell (*Amer. Jour. Pharm.*, 1891, p. 272), has shown that the basic salt that is formed in the preparation of ferric succinate is insoluble in a cold solution of succinic acid or ammonium succinate, but is very soluble in ammonium citrate. He recommends *Liquor Ferri et Ammonii Succinatis*, holding in solution a compound of the composition, $\text{Fe}_2\text{O} \cdot (\text{C}_4\text{H}_4\text{O}_4)_2 \cdot 3(\text{NH}_4)_2\text{C}_6\text{H}_5\text{O}_7$.

Freshly precipitated succinate of iron has a light rose-pink color, which, on drying the salt, becomes brick-red. In the moist state it is rapidly and completely dissolved (when dry with more difficulty), by hydrochloric acid, without effervescence, producing a yellow solution which yields a copious blue precipitate with ferrocyanide of potassium, but no precipitate with ferricyanide of potassium. It should be constantly kept in the moist state, and under water, otherwise it becomes hard and gritty. This salt of iron was introduced to the profession in 1867 (*Amer. Jour. Med. Sciences*, p. 51), by Dr. T. H. Buckler, of Baltimore, Md., as a remedy in *biliary calculi*. To dissolve the cholesterin of which gall-stones are chiefly composed, he recommends the use of chloroform in doses of a teaspoonful 3 times a day, after each meal, continuing its use for several days that these calculi may become dissolved. In cases where there are severe paroxysms of pain, the doses should be given every hour while the pain lasts. To control the fatty or cholesteric diathesis, and thus prevent the further formation of these calculi, the hydrated succinate of iron must be used continuously for 6 or 12 months, in doses of 10 or 12 grains after each meal, though if considerably more be taken it will produce no unpleasant results. This succinate will also be found useful for leucophlegmatic persons disposed to obesity or to fatty degenerations of vital structures.

AMMONII ET FERRI CHLORIDUM, Ammonio-chloride of iron, Ammoniated iron, Ammonium chloratum ferratum, Ferrum ammoniatum.—Mix ferric chloride (9 parts), with ammonium chloride (32 parts), and with constant stirring, evaporate to dryness. It forms a reddish-orange, crystalline powder, somewhat deliquescent, strongly saline, and styptic in taste. Water and

diluted alcohol dissolve it entirely. It contains ferric chloride (Fe_2Cl_6) 7.25 per cent. It was formerly used in doses of from 4 to 12 grains, in *rickets*, *scrofula*, *amenorrhœa*, *epilepsy*, *anemia*, and *general debility*. Its disagreeable taste is somewhat masked by syrup of liquorice. When prepared by sublimation, the yellow product is known as *Flores* (or *Ens*) *martis*.

FERRUM REDUCTUM (U. S. P.)—REDUCED IRON.

SYNONYMS: *Ferrum redactum*, *Iron by hydrogen*, *Iron reduced by hydrogen*, *Powder of iron*, *Quevenne's iron*, and *Ferri pulvis*.

Preparation.—Reduced iron is prepared by the action of hydrogen gas upon pure red-hot ferric oxide, the following reaction taking place: $\text{Fe}_2\text{O}_3 + \text{H}_2 = \text{Fe}_2 + 3\text{H}_2\text{O}$. The process is usually carried out by means of a combustion furnace in an iron reduction tube (a gun-barrel). After the reduction, the current of hydrogen must be maintained until the contents of the tube are cool. The reduced iron is then to be withdrawn and preserved in a dry, stoppered bottle. For details of the process, see *Br. Pharm.*, 1867. The U. S. P. directed the employment of subcarbonate of iron in the preparation of ferric oxide, and the purification of the hydrogen gas by allowing it to pass successively through diluted solution of subacetate of lead and milk of lime. The process of the *British Pharmacopœia* of 1867, directs the drying of the hydrogen. Care must also be taken that the sulphuric acid employed is free from arsenic. (For some valuable remarks on preparing iron by hydrogen, see paper by Prof. W. Procter, Jr., in *Amer. Jour. Pharm.*, Vol. XIX, p. 11, and Vol. XXVI, p. 217).

Description and Tests.—This preparation was introduced into medicine by Quevenne, as a substitute for porphyzied iron. When of a black color it should be rejected. It oxidizes rapidly in damp air, and hence should be kept in dry and well closed bottles. When placed on an anvil and struck with a hammer, it yields a bright, shining scale. The magnet strongly attracts it.

The U. S. P. describes reduced iron as follows: "A very fine, grayish-black, lusterless powder, without odor or taste; permanent in dry air. Insoluble in water or alcohol. When treated with diluted sulphuric acid, it causes the evolution of nearly odorless hydrogen gas, which should not affect paper moistened with lead acetate T.S. (absence of sulphide), and on applying a gentle heat, the iron should dissolve in the acid without leaving more than 1 per cent of residue. When ignited, in contact with air, it glows and is converted into black ferrous-ferric oxide. If 1 Gm. of reduced iron be shaken with 5 Cc. of water, the liquid should not change the color of litmus paper. If 0.5 Gm. of reduced iron be added to 5 Cc. of arsenic-free hydrochloric acid, and the mixture be poured upon a filter while still effervescing, 1 Cc. of the clear filtrate should, after the addition of 2 Cc. of stannous chloride T.S. (see *List of Reagents*, Bettendorff's Test for Arsenic), together with a small piece of pure tin foil, and gentle heating, show no brown coloration within half an hour (limit of arsenic)"—(U. S. P.).

ESTIMATION OF METALLIC IRON.—"Introduce 0.56 (0.559) Gm. of reduced iron into a glass-stoppered bottle, add 50 Cc. of mercuric chloride T.S., and heat the bottle, well stoppered, during one hour on a water-bath, frequently agitating. Then allow it to cool, dilute the contents with water to the volume of 100 Cc. and filter. To 10 Cc. of the filtrate, contained in a glass-stoppered bottle (having a capacity of about 100 Cc.), add 10 Cc. of diluted sulphuric acid, and subsequently decinormal potassium permanganate V.S., until a permanent red color is produced. The number of cubic centimeters of the volumetric solution required, when multiplied by 10, will indicate the percentage of metallic iron. To confirm the assay, decolorize the liquid by a few drops of alcohol, then add 1 Gm. of potassium iodide, and digest for half an hour at a temperature of 40° C. (104° F.). The cooled solution, mixed with a few drops of starch T.S., should require not less than 8 Cc. of decinormal sodium hyposulphite V.S. to discharge the blue or greenish color (each cubic centimeter of the volumetric solution indicating 10 per cent of metallic iron)"—(U. S. P.).

According to the U. S. P. assay directions, reduced iron should contain 80 per cent of metallic iron. Yet great variations have been observed in commercial specimens, reaching as low a limit as 18 per cent, due partly to incomplete reduction, partly to deterioration by oxidation in moist air. Mr. L. F. Kebler (*Amer.*

Jour. Pharm., 1896, p. 198), found 6 commercial specimens to vary in metallic iron from about 38 to 84 per cent. Among adulterations of reduced iron has occurred plumbago (graphite), the presence of which, however, can easily be recognized by being insoluble in diluted sulphuric acid.

Action, Medical Uses, and Dosage.—When this powder of iron is properly prepared, and not without, it forms a valuable tonic, and is considered to be superior to any other form of metallic iron for medicinal employment. It is without inky flavor, and is not liable to blacken the teeth. Its tendency to oxidize, and the unpleasant eructations of hydrogen gas to which it gives rise, render it objectionable. It may be used in *chlorosis*, *anemia*, and in all diseases in which there is a deficiency of red blood corpuscles. It may be used to antidote acute poisoning from the copper compounds. The dose is from 1 or 2 to 10 or 12 grains, in pill or bolus, but preferably suspended in water.

Related Preparation.—*FERRUM PULVERATUM*, *Pulverized iron*, known also as *Porphyrized iron* (*Ferrum porphyrizatum*), and *Alcoholized iron* (*Ferrum alcoholisatum*). This is a European product, liable to be confounded with reduced iron. It is prepared by mechanical processes (filing, etc.), from a good grade of cast iron, and thus necessarily contains carbon. It is denser than reduced iron, which it resembles, but it exhibits a luster (which the former lacks), and the hydrogen evolved from it has an unpleasant odor, that from reduced iron being inodorous. It refuses to burn when touched with a flame. It dissolves in hydrochloric and sulphuric acids, leaving a small amount of black, undissolved substance, and should exhibit but traces of hydrogen sulphide.

FICUS (U. S. P.)—FIG.

"The fleshy receptacle of *Ficus Carica*," Linné, "bearing fruit upon its inner surface"—(U. S. P.).

Nat. Ord.—Urticacæ.

COMMON NAMES AND SYNONYMS: *Fici*, *Figs*; *Fructus caricæ*, *Ficus passa*, *Caricæ*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 228.

Botanical Source.—The fig tree is usually about 10 or 12 feet in height, but in warm latitudes exceeds this by 8 or 12 feet additional. The trunk is crooked, usually about $\frac{1}{2}$ foot in diameter, with a grayish or grayish-brown bark, and round, green, or russet branches, covered with a coarse, short down. The leaves are alternate, large, rough on the upper side, coarsely downy beneath, cordate, 3 or 5-lobed, or almost entire, coarsely serrated, and petioled. The flowers are green, placed upon the inside of a turbinate, fleshy, closed receptacle, in the axils of the top leaves; male flowers, near the umbilicus, stamens 3, calyx 3-lobed; female flowers, calyx 5-lobed, ovary 1. The receptacle or fruit is solitary, axillary, more or less pear-shaped or almost round, succulent, sweet and pleasant to the taste. The seeds are small and numerous (L.—Wo.).

History and Chemical Composition.—The fig tree is believed to be a native of Persia and Asia Minor, but at present is raised in all mild latitudes. The structure of its fruit is peculiar; at first it is nothing more than a fleshy receptacle, but, as it advances to maturity, minute flowers form in a cavity which occupies the center of the mass and communicates outwardly by a small round aperture at the summit, and these flowers are succeeded by many small roundish seeds. While young, the fig abounds, like the trunk and branches, with a milky, aromatic, acrid juice, destitute of sweetness; but as it matures, sugar and mucilage are formed, and the acidity disappears. Its shape is generally turbinate or pear-shaped, of the size of an apricot, of various colors, some being whitish, others reddish or yellow, with a small pit or depression at the larger end, and of an agreeable, sweet, mucilaginous taste, and, when ripe, is sweet, high-flavored, and wholesome, but if eaten to excess, occasions flatus, intestinal pains, and looseness of the bowels. Figs are generally dried in the sun, sometimes in ovens, and are packed in baskets or drums. If left until perfectly ripe they dry on the trees, and are gathered as *dried figs*. The *Smyrna figs* are best. They are more or less flattened by pressure, and are covered with saccharine granules, which, in summer, contain numerous minute insects, are of a yellowish or brownish color, and rather translucent. The *Smyrna* or *Turkey figs* are pulpy and large, while a smaller, dried variety is known as *Greek figs*. Figs that retain their natural form somewhat, not having been compressed in packing, are known as *natural figs*, while

another commercial variety is known as *pulled figs*, on account of having been rendered supple by kneading. They contain sugar of figs, 62.5; fatty matter, 0.9; extractive with chloride of calcium, 0.4; gum with phosphoric acid, 5.2; woody fiber, seeds, and water, 1.60 (P.). Starch is abundant in the unripe fig. The milky juice of the common fig tree (*Ficus Carica*) contains a digestive ferment (see *Amer. Jour. Pharm.*, 1880, p. 628, and 1887, p. 150).

Description.—Figs are officially described as follows: "Compressed, of irregular shape, fleshy, brownish, or yellowish, covered with an efflorescence of sugar; of a sweet, fruity odor, and a very sweet, mucilaginous taste. When softened in water, figs are pear-shaped, with a scar or short stalk at the base, and a small, scaly orifice at the apex; hollow internally; the inner surface covered with numerous yellowish, hard achenes"—(U. S. P.).

Action and Medical Uses.—Figs are nutritive, emollient, demulcent, and aperient, and are used in *costive habits*, and to flavor gruels, decoctions, etc. Roasted or boiled, they may be applied as a suppurative poultice to *gum-boils*, *buboes*, *carbuncles*, etc. A poultice of dried figs and milk will remove the stench of cancerous and fetid ulcers (Billroth).

Related Species.—*Mesembryanthemum crystallinum*, Linné (*Nat. Ord.*—Ficoideæ); *Diamond fig*, *Ice plant*. Europe. This plant has round-ovate leaves, and whitish or reddish blossoms. The plant is covered with vesicles, which glisten in the light, and is odorless and saline to the taste. Its juices contain salts, chiefly sodium and potassium compounds, oxalates being especially prominent. It has been used in Europe for various cystic disorders, chiefly *enuresis* and *dysuria*, *dropsy*, and as a demulcent in *pulmonic complaints*. Dose of expressed juice, 3iv in a day. In South Europe it is gathered to furnish alkali for glass works (Hogg).

Mesembryanthemum edule, *Hottentot's fig*.—Sandy plain of Cape of Good Hope. Fruit edible and leaves used as pickles. Juice reputed useful externally in burns, and internally in *thrush* and *dysentery* (Hogg).

Mesembryanthemum tripartitum, *Rose of Jericho*, *Flower of Crete*.—The natives of South Africa administer the water in which the fruit has lain to women to facilitate easy delivery in labor (Hogg).

FENICULUM (U. S. P.)—FENNEL.

"The fruit of *Feniculum capillaceum*, Gilibert"—(U. S. P.) (*Feniculum vulgare*, Gærtner; *Feniculum officinale*, Allioni; *Anethum Feniculum*, Linné; *Meum Feniculum*, Sprengel).

Nat. Ord.—Umbelliferae.

COMMON NAMES AND SYNONYM: *Common fennel*, *Fennel fruits*, *Fennel seeds*, *Sweet fennel*, *Roman fennel*; *Semen fœniculi*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 123.

Botanical Source and History.—FENICULUM CAPILLACEUM (*Feniculum vulgare*), or *Common fennel*, is a biennial or perennial plant, with a whitish, tap-shaped root, the whole herb being smooth, and of a deep glaucous green. The stems are 3 or 4 feet high, erect, solid, round, striated, smooth, leafy, and copiously branched. The leaves are alternate and triply pinnate; the leaflets acute; thread-like, long, more or less drooping; the petioles with a broad, firm, sheathing base. The flowers are in large, terminal, very broad, flat umbels, with very numerous smooth, angular, rather stout rays; partial rays much more slender, short, and very unequal. Bracts or involucre are wanting. Calyx none. Styles very short, with large, ovate, pale-yellow base. The fruit is ovate, not quite 2 lines long, about a line in breadth, pale, bright brown and smooth; the ridges are sharp, with but little space between each; the lateral ones being rather the broadest; they are terminated by a permanent conical disk. The *Index Kewensis* considers the species *Feniculum vulgare*, Miller, to represent those variously described as *F. capillaceum*, *F. officinale*, *F. dulce*, *F. Panmorium*, and others. Fennel is a native of Europe, growing wild upon sandy and chalky ground, and flowering in July (L.).

FENICULUM OFFICINALE, Mérat and De Lens, or *Large fennel*, is very much like the preceding, and the two are sometimes confounded; but its leaves are smaller, leaflets shorter, fruit paler, twice as heavy, much longer, somewhat curved, of a sweeter and more agreeable taste (L.). It inhabits the southern parts of Europe, and is naturalized in this country.

FENICULUM DULCE, De Candolle, or *Sweet fennel*, and sometimes confounded with *F. capillaceum*, has somewhat the appearance of the latter, only it is not so

large, seldom exceeding 12 inches in height, and the rays of its umbels being less in number by at least one-half; the fruit likewise varies considerably, being narrow, oblong, 3 lines long, pale, dull brown, smooth; ridges sharpish, with a space between each for a convex line, indicating the vittæ, the lateral ones rather the broadest. It inhabits the same countries as the preceding variety, and is cultivated for culinary purposes.

At one time these plants were placed in the genus *Anethum*, Linné, but De Candolle and Gærtner removed them to the present genus on account of the dissimilarity of the seed.

The seeds or mericarps of these plants possess nearly the same peculiar, agreeable spicy odor and flavor. There are 3 kinds in commerce, the *Sweet fennel*, which is also known as *Roman fennel*, and is of a pale green color; the brown fruits are known as *German* or *Saxon fennel*, while those from the uncultivated plants of France are called *Bitter* or *Wild fennel*. These species differ also in the length of their seeds, the Roman being the longest, and in the character of their striations. An East Indian variety, termed *Indian fennel*, is derived from *F. Panmorium*, De Candolle, now held to be a variety of *F. capillaceum* of Gilibert. The latter is not common in American markets. Water, at 100° C. (212° F.), takes up their properties by infusion, but not so thoroughly as alcohol. FENNEL ROOT is employed somewhat in Europe. Its taste and odor is that of fennel, though milder.

Description.—"Oblong, nearly cylindrical, slightly curved, from 4 to 8 Mm. ($\frac{1}{4}$ to $\frac{1}{2}$ inch) long, brownish or greenish-brown; readily separable into the 2 prominent mericarps, each with 5 light brown, obtuse ribs, 4 oil-tubes on the back, and 2 or 4 oil-tubes upon the flat face; odor and taste aromatic, anise-like"—(*U. S. P.*).

Chemical Composition.—The aromatic properties of these seeds are due to a volatile oil (see *Oleum Fœniculi*). The fruits also contain sugar, ash (about 7 per cent), and about 12 per cent of fixed oil; the root, sugar, starch, and volatile oil.

Action, Medical Uses, and Dosage.—Carminative, stimulant, galactagogue, diuretic, and diaphoretic. Used in *flatulent colic*, and as a corrigent of unpleasant medicines. May be used in *amenorrhœa* and in *suppressed lactation*. Dose of powdered seeds, from 10 to 30 grains; infusion (grs. xl. to aqua Oss), 1 teaspoonful (infants) to wineglassful (adults).

FENUM GRÆCUM.—FENUGREEK.

The seeds of *Trigonella fœnum græcum*, Linné.

Nat. Ord.—Leguminosæ,

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, Plate 71.

Botanical Source.—The source of this drug is the cultivated plant which grows to the height of 1 foot. Its stem is almost simple and bears trifoliate leaves. The leaf segments are articulated, obovate or oblong, wedge-shaped, and denticulate. The flowers are of a light yellow hue, sessile, and solitary. The fruit is a beaked, compressed, curved legume, containing about 15 or 16 seeds.

History and Description.—Fenugreek is an annual plant, native of west Asia, but is naturalized in Africa, south Europe, and India. It is cultivated for its seeds in Germany, France, Africa, and Asia. The seeds are small ($\frac{1}{8}$ inch long, $\frac{1}{16}$ inch broad, $\frac{1}{16}$ inch thick), hard, compressed, oblique, rhombic, having an oblique groove on each flattened surface. Externally they are pale brownish-yellow and yellow internally. Their odor is to some persons decidedly disagreeable, yet aromatic. The taste is mucilaginous, bitter, and nauseous. The powder is occasionally adulterated with starchy material, which may be detected with iodine since the seeds of fenugreek are free from starch. Powdered fenugreek is usually purchased by pharmacists, owing to the difficulty of powdering the seeds. Large quantities of powdered fenugreek are consumed in "condition powders," and as constituents of mixtures used in the treatment of hogs.

Chemical Composition.—Fenugreek seeds, as before stated, contain no starch; their constituents are a little tannin, mucilage, volatile and fixed oils, and a peculiar bitter body. Jahns found the alkaloid, *trigonelline* ($C_8H_{11}NO_2$) and *choline* ($C_4H_{11}NO_2$), the latter base being also a constituent of certain animal secretions (see *Fel Bovis*).

Action, Medical Uses, and Dosage.—The Greeks were acquainted with fenugreek, it being one of the important medicines employed by that people. The only property worth mentioning is its emolliency. A poultice (or plaster or ointment) of the powdered seeds, or a decoction, has been used on inflamed parts, and the latter has been used as a rectal and vaginal wash to soothe *irritation or inflammation*; it has likewise been used to allay irritation of the throat and breathing passages. The decoction is prepared from 1 ounce of the seeds and 1 pint of water. Burns, etc., may be dressed with its bland oil. The infusion or tincture may be used as a tonic to improve digestion. It relieves *uterine irritation* and acts as an emmenagogue. *Respiratory irritation* is thought to be relieved by its internal use, and a sack of the ground seeds is regarded as a valuable application in *chronic affections of the stomach, bowels, and liver* (Scudder, *Spec. Med.*).

FORMALDEHYDUM.—FORMALDEHYDE.

FORMULA: $\text{H.COH}=\text{CH}_2\text{O}$. MOLECULAR WEIGHT: 29.93.

SYNONYMS: *Formic aldehyde, Methyl aldehyde, Oxymethylene.*

Source, History, and Preparation.—Formaldehyde is a gas, and was discovered in 1867, by Von Hoffman, who obtained it by passing the vapor of a mixture of methylic alcohol and air over red-hot, finely-divided platinum. A useful modification of this process by Prof. O. Loew, is described in *Amer. Jour. Pharm.*, 1886, p. 440. Formaldehyde is of great importance in the physiology of vegetable life. According to Baeyer it is produced in plants from carbon dioxide and atmospheric moisture, by the action of the sun's rays in the presence of the chlorophyll of the leaves, thus: $\text{CO}_2 + \text{H}_2\text{O} = \text{CH}_2\text{O} + 2\text{O}$. It then becomes the mother-substance of carbohydrates, *e. g.*, starch and sugar (O. Loew's *formose*). Baeyer declares formaldehyde to be the natural protector of the tender portions of the plant against bacterial invasion.

Formaldehyde was introduced into medicine by Berlioz and Trillat in 1890. Its germicidal properties, however, had been established by Loew in 1888. The preparations that have been used in medicine, and for economic purposes, are 40 per cent solutions of this gas, forms of which are known by the trade names *formalin, formal*, etc. For disinfecting purposes, formaldehyde may be prepared conveniently by the lamp process introduced in recent years, whereby the gas is generated, as in Hoffmann's process, by incomplete combustion of methyl alcohol. In this connection it may be said that a simple and effective formaldehyde lamp is manufactured for physicians' use by Eli Lilly & Co., of Indianapolis (*Amer. Jour. Pharm.*, 1897, p. 223).

Description and Tests.—Solution of formaldehyde (40 per cent), as found in commerce, is a very volatile, pungent, peculiarly aromatic fluid. It has an acid reaction, due to the presence of formic and acetic acids, and a density of 1.070. It hardens animal tissues, and renders gelatin insoluble, even in hot water and alkaline media. It should be kept securely stoppered. Formaldehyde, when warmed with an ammoniacal silver solution, reduces silver, which deposits a mirror on the vessel. This property is shared by aldehydes in general. A distinctive reaction which affords a means for an easy quantitative determination of formaldehyde, consists in its combination with ammonia, hexamethylenamine resulting. This compound, which is crystallizable, and has the composition $(\text{CH}_2)_6\text{N}_4$, yields formaldehyde again upon distillation with sulphuric acid. Of the various qualitative tests proposed for formaldehyde, *O. Hehner's Test* is sensitive and fairly characteristic. It is said to detect 1 part of formaldehyde in 200,000 parts of liquid, and is carried out as follows: To the liquid to be tested, *e. g.*, the distillate from a sample of milk, etc., add 1 or 2 drops of a weak solution of phenol (1 drop of phenol to 1 fluid ounce of water). Into a test-tube introduce a layer of concentrated, colorless sulphuric acid. Carefully pour the suspected liquid in a layer over the sulphuric acid so that but slight admixture takes place at the surface. If formaldehyde is present it will be indicated by a pink or vivid crimson zone. It should not give an orange-yellow or brown coloration (absence of acetic aldehyde in strong solution). *Lebbin's Test* is very delicate, detecting 1 part of formaldehyde in 10,000,000 parts of water. It is conducted as follows: To

the liquid to be tested add a small quantity of a 50 per cent alkali solution (sodium or potassium hydroxide), followed by 1 drop of a 5 per cent solution of resorcin. Boil the mixture. If formaldehyde is present a crimson solution results. No yellow or brown coloration should result (absence of acetic aldehyde). For other tests, as well as an interesting resumé of the subject of formaldehyde, see F. C. J. Bird, *Pharm. Jour.*, 1896, Vol. III, p. 269, or *Amer. Jour. Pharm.*, 1896, p. 617.

Action, Economic and Medical Uses, and Dosage.—Formaldehyde is exceedingly volatile, and the vapor given off from its solutions is irritant to the nasal, faucial, and ocular mucous membranes. When concentrated it affects the cutaneous tissues similarly to phenol, leaving the surfaces roughish, white, and after a time insensitve. Its application to the skin does not produce pain. Of its internal effects but little is known. No ill effects followed the ingestion of a considerable amount of the 1 per cent solution (Rideal), and of the paraformaldehyde as large a dose as 90 grains has been administered as an intestinal antiseptic without harmful results. Owing to its action upon ammonia and ammonia bases, hydrogen sulphide, mercaptan, etc., forming odorless compounds, it has been used both in solution and vapor as an effective deodorant, the putrescent odor of decaying flesh being instantly removed by it. A very small quantity of the 10 per cent solution quickly deodorizes feces, brine, putrid meat, etc. Not only does it overcome odors, but it exhibits remarkable preservative powers. Thus the vapor from a pledget of cotton impregnated with 6 or 8 drops of the 40 per cent solution will preserve fish, meat, etc., for several days in a well covered vessel, even in hot weather. Neither odor nor taste is imparted to flesh thus preserved. Such organisms as give rise to lactic and butyric fermentation as well as other organisms producing secondary fermentation, are destroyed by formaldehyde. This can be accomplished with solutions (1 to 20,000 to 1 to 10,000) which are too weak to interfere with the development and growth of the *Saccharomyces cerevisiae*, or with the production of alcohol.

Tables have been made for the use of formaldehyde solutions in various directions, which, however, are largely as yet experimental. The generation of formaldehyde gas for purposes of disinfection and sterilization has recently assumed importance. Specially constructed lamps have been devised for the direct generation of the vapor, either from methyl alcohol or from the polymerized formaldehyde or paraformaldehyde. Rooms, cellars, vaults, libraries, hospitals, schools, furniture, drapings, surgical dressings and appliances, etc., may be deodorized and disinfected by means of this gas. This substance has the advantage of being non-injurious to fabrics, metals, wood, and the common colors, except violet and light red. Prof. F. C. Robinson (*Jour. Amer. Public Health Assoc.*), states that at least a quart of methyl alcohol should be used in disinfecting an ordinary living-room. Several hours exposure to the gas destroyed the pathogenic bacteria of typhoid fever and diphtheria, even when folded between mattresses (Robinson). Koch's bacillus tuberculosis and other bacteria are said to be destroyed by it, the bacillus subtilis and bacillus mesenterica being possible exceptions. Roux, Trillat, Bosc, Wortmann, Stahl, Aronson, and Berlioz, are among the European experimenters who endorse formaldehyde as the leading disinfectant and antibacterial agent. In this country De Schweinitz and Kinyoun (*Public Health Reports*, Vol. XII, No. 5, 1897), have made extensive investigations. Test-cultures of bacteria have been the means used to demonstrate the active and destructive properties of the gas upon pathogenic micro-organisms. Kinyoun states it difficult to disinfect the interior of closed books, although it is claimed to be accomplished by others, and he questions its effectiveness in the interior of upholstered furniture, etc., unless very large amounts of the gas be employed. To accomplish results an exposure of at least one day is necessary, and the larger the quantity generated the better the results.

The various published reports would lead one to believe that the uses of formaldehyde for disinfecting purposes are practically without limit. This, however, proves not to be the case, for well-conducted experiments have satisfactorily demonstrated that it is of value chiefly as a surface disinfectant, and is of doubtful utility when deep penetration is required (Doty, *N. Y. Med. Jour.*). It has also been shown that it acts best in a chamber from which the air has been exhausted. Park and Guerard of the New York City Health Department, who made compre-

hensive and thorough bacteriological tests with formaldehyde, endorse it only for surface disinfection, and state that the cost of disinfection by it is not greater than when sulphur is employed (see paper by G. L. Taylor, *Amer. Jour. Pharm.*, 1898, pp. 195-201).

The germicidal power of formaldehyde is undoubtedly due to its chemical combination with albuminous and nitrogenous materials, as bacteria are albuminoid in character and feed upon albuminoids. The penetrating properties of formaldehyde were demonstrated by Roux and Trillat by exposing to the gas liberated in a room gelatin-coated cubes of glass, whereby the gelatin was rendered insoluble even in hot water. Though destructive to micro-organisms, formaldehyde is innocuous to the higher forms of life. Unfortunately, it has practically no effect upon bedbugs, lice, roaches, etc. Formaldehyde has been advised as a preservative of vegetable solutions and botanical specimens. Unless in considerable amounts, it fails to prevent the formation of mold, as its action upon the low forms of vegetable life is not so pronounced as upon bacteria. Formaldehyde is used in photography for hardening purposes. It is declared superior to absolute alcohol, chromic acid, or corrosive sublimate for hardening histological materials, as the tissues become hard in three days, retain their cell forms, do not become brittle, and stain well.

Formaldehyde has had a limited use in practical medicine. Painted upon the parts the solution gives relief and prevents extensive inflammation from the bites of gnats, mosquitoes, and small animals. Generated in a room, the vapor is said to drive away mosquitoes, flies, and similar pests. Washing the feet and wiping the inner soles of the shoes with the solution (2 per cent) is said to be effectual in fetid sweating of the feet—*bromidrosis*. Salter, of Guy's Hospital (*Brit. Med. Jour.*, 1896), praises it in ringworm of the scalp. It has been advised to sprinkle formaldehyde upon the clothing and bedding of those suffering from typhoid fever, while for the purpose of disinfecting the excreta it is regarded with much favor. In diphtheria it has been vaporized and the vapor inhaled so as to reach parts inaccessible by ordinary methods of making local applications. Its clinical value in this disease remains, however, to be established. Dr. Solis-Cohen (*Therap. Gaz.*, 1897), regards it as the best agent for the local treatment of the various forms—ulcerative, infiltrative, and vegetative—of tuberculosis. He first cleanses and cocainizes the parts, after which they are thoroughly rubbed with a 1 to 10 per cent solution of commercial formalin—practically equivalent to $\frac{1}{4}$ to 4 per cent of formic aldehyde. Used in a properly constructed inhaler, the diluted vapor from formalin and water has been advised as useful in catarrhal respiratory affections and in the early stages of pulmonary tuberculosis. Whooping-cough appears to have been alleviated by the inspired vapor generated directly into the apartments of the patient or when used in the form of spray.

Solution of formaldehyde, in strength varying from 1 to 5 per cent, appears to give excellent results in gonorrhœa, particularly in gonorrhœal vaginitis. It may be used for other infectious diseases of the genitalia. Prof. De Smet (*Rev. Int. de Med. et de Chir.*) reports 60 cases of gonorrhœa in women, in which formaldehyde gave complete satisfaction. The vulva was first washed with a warm 1 per cent solution, after which, by means of a speculum, he poured a 2 to 5 per cent solution into the vagina and by means of a swab, worked this into the folds of the vagina, and about the cervix uteri. Where the infection had reached the cervico-uterine cavity a 2 per cent solution was injected into it. In cases where the cervix was ulcerated a formalin-impregnated (1 per cent) tampon of cotton or gauze was placed upon the sore and allowed to remain 2 or 3 hours. In severe cases of fungous blennorrhagic endometritis the parts were first curetted. The burning of the mucous membrane produced by the 5 per cent solution is but transitory.

Probably the greatest field for formaldehyde outside of its use as a general disinfectant, particularly in zymotic diseases, will be in surgical practice. The vaporization of wounds with it has already received the endorsement of practical men. For irrigation purposes in accidental or surgical wounds a 1 per cent solution has been found most practical. Prof. L. E. Russell (*Er. Med. Jour.*, 1898, p. 296) recommends it for rendering aseptic instruments and diseased tissues. He used a full strength solution of formaldehyde to mop out the pelvic cavity after the removal of a large tubo-ovarian abscess, some of the contents of which had escaped

into the surrounding parts. He formerly advised it half strength for washing out pus cavities, and for packing, directed gauze wrung out of equal parts of formaldehyde and sterilized water, but further use of it leads him to offer the following: "After a more extended use of formaldehyde, I am quite satisfied that it is a remedy that will require more care in its use upon open wounds or in the cavities mentioned than I had been led to believe from my former experience. To illustrate, I have been treating a *carcinoma* of the recurring form, following a breast excision, and I used the pure formaldehyde hypodermatically to check the infiltration of the carcinoma into the cutaneous and subcutaneous tissue. I found that by this method of treating the lesion it produced mummification of the skin and an escharotic condition of considerable importance. I therefore instructed the nurse to moisten pieces of gauze with the full strength formaldehyde and apply it to the skin-tissue over the region of the carcinoma. I found that, by the confinement of this gas by the gauze coverings, it produced an anæsthesia of the skin, and the formaldehyde infected the subcutaneous tissue to the depth of $\frac{1}{2}$ inch, making necrotic and completely mummifying the tissue beneath the moistened piece of gauze. I shall, therefore, have to correct the impression that I first formed of this new remedy in the treatment of *pus cavities* and *contaminated wounds*; that is to say, it must be used greatly diluted from that which I first suggested by way of experiment in the use of this new remedy for new conditions. I now believe that we have the ideal remedy to assail carcinomatous tissue where it would seem impossible to use the knife, or in those cases where the patient would not submit to more heroic treatment. I can readily see where this new remedy would be one of the best known in cases of *carcinoma uteri*, in those conditions where the discharge had become so offensive and where the invasion of the carcinoma had become so extensive that only palliative means could be resorted to. This remedy, in wounds of little contamination, should be used in the proportion of, say 1 to 20 or 50; and in those conditions where there seems to be a pyogenic membrane, it could be used in the proportion of 1 to 5 or 10. I do not know at this time just what results we should obtain in the use of this remedy if it be applied to diseased tissue and not protected by gauze, but allowed to evaporate. I am of the opinion that it could not even act as an escharotic; but if used with the gauze, covering the tissue and excluding the chances of evaporation, I believe it far excels any cancer plaster or escharotic ever presented to the profession, inasmuch as it anæsthetizes the tissue, stops almost instantly on its application the offensive odor, and penetrates deeply and speedily into the tissues exposed to its influence as above described. For irrigations and dressings with formaldehyde, I believe that the proper strength would be 1 ounce of the commercial strength to 1,000 of distilled water. Where the wound is infected, it can be increased to 5 volumes to 1,000 volumes of water" (*E. M. J.*, 1898, p. 435).

Altogether formaldehyde appears to have a promising future, and careful experimentation will determine its field of usefulness. Meanwhile, let us not expect too much of it, nor should we condemn it if it does not accomplish all that we are led to expect, until thorough tests have been given it at the hands of our physicians and surgeons.

Related Preparations.—**PARAFORMALDEHYDE** ($[\text{CH}_2]_n\text{O}_n$), *Paraformic aldehyde*, *Trioxymethylene*. This is a polymerized form of formaldehyde, and may be obtained by warming an aqueous solution of this gas, whereby part of it escapes and the remainder is transformed into a solid, crystalline substance, of the above composition, insoluble in water, alcohol, and ether. Its fusing point is 152°C . (305.6°F .), but it evolves vapors of formaldehyde at temperatures below 100°C . (212°F .). It may be used to disinfect bandages and other dressings.

TANNOFORM ($\text{CH}_2[\text{C}_6\text{H}_4\text{O}_6]_n$).—A condensation product of formaldehyde and tannic acid, occurring as a light reddish-white powder. At 230°C . (448°F .), it melts with decomposition. Water does not dissolve it, but it is soluble in alcohol, ammonia water, and such alkaline solutions as those of soda or sodium carbonate. Tannoform is tasteless and in doses of 15 grains is said to be non-irritant to mucous tissues. It is employed chiefly as a siccative antiseptic in the treatment of *hyperidrosis* and *bromidrosis*, in which it is said to excel salicylic acid. It is also reputed useful in *old wounds*, *ulcers*, *weeping eruptions*, *bed-sores*, *osena*, *soft chancre*, and *diabetic pruritis*. Dr. Sziklai has recently employed this compound with marked success in *diarrhæa* and *intestinal catarrh* (see *Pharm. Centralh.*, 1897, p. 776). It may be used pure and in from 20 to 50 per cent triturations with starch or talcum. An ointment is sometimes preferred.

BROMALIN ($\text{C}_6\text{H}_{12}\text{N}_4\text{C}_2\text{H}_4\text{Br}$), *Bromethyl-formin*, *Hexamethylenetetramine-bromethylate*.—White crystalline powder or colorless scales, readily soluble in water. When heated with sodium carbonate formaldehyde is evolved. In solution it has but little taste, but it is best

administered in capsules or in mixtures sweetened with syrup of orange. Reputed in doses of 30 to 60 grains a good nerve sedative for women and children, particularly those suffering from *neurasthenia* or *epilepsy*. In the latter disease it is regarded as less powerful than potassium or sodium bromides, but is reputed to be free from their deleterious effects.

GLUTOL, Formalin-gelatin.—This odorless powder is reputed a non-irritative and non-toxic antiseptic dressing for wounds. For fresh wounds it should be applied freely soon after the injury, and allowed to remain on the parts until they are healed. In older injuries we are directed to change the primary dressing in 24 hours. It may be used upon burns, in sinues, etc.

FRANCISCEA.—MANACA.

The root and stem of *Franciscea uniflora*, Pohl (*Brunfelsia Hopeana*, Benthani).
Nat. Ord.—Solanaceæ.

COMMON NAMES: *Mercurio-vegetal*, *Manaca*, *Manacón*, *Camganiba*, *Geratacáca*.

Botanical Source.—This shrub is much branched, and is extremely variable as regards the shape of the leaves presenting obovate, oblong, obtuse, or acute ones on the same branch. The leaves are alternate, from 1 to 3 inches long, narrowing at the base, smooth, and, in texture, intermediate between coriaceous and membranaceous. The flowers are usually solitary, white, blue, or violet, and terminal on the smaller branches. Stamens 4, and ovary 2-celled, and surrounded by a fleshy ring. Stigma is coated with a glutinous, green, fungoid substance, serving to retain the pollen (DeC.).

History and Description.—This plant is occasionally cultivated in green-houses. It is a native of the American equatorial sections. Two kinds of manaca are found in commerce (*white* and *red*), being undoubtedly of different botanical origin. Jamaica dogwood (*Piscidia Erythrina*) is known in some sections of South America under the name *manaca*. The leaves are sometimes employed medicinally as well as the root and stems. As found in commerce, the drug consists of both stem and root, in pieces ranging from $\frac{1}{4}$ to 1 inch in thickness, and 6 to 8 inches in length. The wood is hard, tough, and yellowish-red in color, and surrounds a narrow pith; the bark, which closely adheres to the wood, is deep-brown in color and smooth when young, but in the older species the bark is rust-brown, rough, and scaly. It has a bitter taste, but no odor. Fluid extract of manaca was introduced to the American medical profession through the efforts of Parke, Davis & Co.

Chemical Composition.—The drug was analyzed by R. Lenardson, of Dorpat, 1884, who found the bark and the wood of root and stem to contain two proximate principles, one a weak, amorphous alkaloid of bitter taste, which (previously indicated by Prof. Dragendorff) he called *manacine*; the other fluorescent body is most probably identical with *gelsemic acid*. Manacine is toxic in large doses, soluble in water and alcohol, but insoluble in ether and chloroform. Its solutions are prone to decomposition, a brownish resin being formed. Brandl, in 1895, found that *manacine* decomposes in the presence of water at higher temperatures, a new compound, *manacéine*, and a resinous and fluorescent substance resulting, the latter being identical with *æsculetin* (*Jahresb. der Pharm.*). A complete analysis of the drug, by John L. Erwin, is reported in the *Pharmacology of the Newer Materia Medica*, 1892, published under the auspices of Parke, Davis & Co.

Action, Medical Uses, and Dosage.—This agent was introduced as a remedy for *rheumatism*, the decoction having been so employed by the people living in the region of the Amazon. It was also reputed to be a remedy for syphilitic complaints, hence its name, *vegetable mercury*. Manaca has an influence over the nervous structures and the glands, being particularly diuretic. Painful sensations in the back and head are said to be the first effects of the decoction, which sensations are followed by profuse diaphoresis. Moderate doses induce emesis and purgation, greenish stools being passed. Gastro-intestinal effects from large doses may produce death, while its immoderate employment during pregnancy has occasioned abortion. Undoubtedly the agent acts in rheumatic complaints much like mezereum, guaiac, etc. It may be given in the subacute forms of rheumatism affecting the muscles and tendons, but is of little or no value in that form affecting the joints. Dull, heavy pains and soft skin, without fever, seem to be the symptoms indicating it. The dose of the fluid extract of manaca is from 10 to 60 minims.

FRAGARIA.—WOOD STRAWBERRY.

The fruit, leaves, and root of *Fragaria vesca*, Linné.

Nat. Ord.—Rosaceæ.

COMMON NAMES: *English strawberry*, *Alpine strawberry*, *Wood strawberry*.

Botanical Source.—Strawberry is a perennial plant, with a creeping, knotty root. The stems are trailing, with stolons often creeping several feet. The leaves are pubescent and trifoliate; the radical ones on long foot-stalks; the leaflets obovate-wedge form, coarsely serrate, and sessile; the stipules lanceolate-oblong, cohering with the base of the petiole. The flowers, borne on scapes, are white, one or several; the peduncles are erect or nodding. The calyx is concave, deeply 5-cleft, with an equal number of alternate exterior segments or bracteoles; petals 5, and obcordate. Stamens numerous and small; styles deeply lateral; stigmas sessile and small; ovaries numerous. The receptacle in fruit is much enlarged and conical, becoming pulpy and scarlet, bearing the minute dry achenia scattered over its surface. In this species the achenia are superficial on the conical or hemispherical fruiting receptacle, not sunk in pits; in the *F. Virginiana* the achenia are imbedded in the deep pits of the receptacle (W.—G.).

History and Chemical Composition.—This is a European species, presenting exhaustless varieties, which are extensively cultivated, flowering from April to May, and ripening its fruit in May and June. The *F. Virginiana*, Ehrhart, or wild strawberry; *F. canadensis*, or mountain strawberry; *F. grandiflora*, or pine-apple strawberry, and the other varieties possess similar properties. The fruit of all the varieties is highly fragrant and delicious, the cultivated varieties frequently being very large. The fruit contains about equal parts of citric and malic acids, sugar, mucilage, pectin, water, peculiar volatile aroma, woody fiber, and pericarps. The root contains a glucosid called *fragariamarin*, not easily soluble in water, alcohol, or ether. Upon hydrolysis with acids it splits into sugar and *fragarin*, a red amorphous substance (C. E. Sohn, *Dictionary of Active Principles of Plants*, 1894).

Action, Medical Uses, and Dosage.—The fruit, used very freely, has been highly spoken of in *calculus disorders*, likewise in *gout*, and the juice will dissolve the hard concretion called "*tartar*," which forms on the teeth, and without injuring them. With some, strawberries disagree, causing disordered digestion, and frequently a rash-like eruption on the surface. The grains or seed-like pericarps are indigestible, and sometimes cause irritation of the bowels. Strawberry-juice, or the syrup, added to water, forms a refreshing and useful drink for febrile patients; care being taken that the grains are removed by filtering or expressing the juice or syrup through a piece of muslin. Strawberries eaten with cream are, as a rule, injurious to dyspeptics. The leaves are slightly astringent, and have been used, in infusion, in *diarrhœa*, *dysentery*, and *intestinal debility*; the roots are diuretic, and have been beneficially used, in infusion, in *dysuria*, *gonorrhœa*, etc. The leaves of the wild strawberry, gathered after the ripening of the fruit, and dried in the sun, or in heated pans, afford a greenish and slightly astringent infusion, like that of the Chinese tea, with similar diaphoretic, diuretic, and excitant properties.

FRANGULA (U. S. P.)—FRANGULA.

"The bark of *Rhamnus Frangula*," Linné, "collected at least one year before being used"—(U. S. P.) (*Frangula Alnus*, Miller; *Frangula vulgaris*, Reichenbach).

Nat. Ord.—Rhamnææ.

COMMON NAMES: *Buckthorn* (U. S. P., 1880), *Alder buckthorn*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 65.

Botanical Source.—The alder buckthorn is a smooth shrub growing to the height of from 10 to 15 feet. Its leaves are oval, obovate, or elliptic, broad, obtuse, and entire, or scarcely sinuate. The under surface is faintly downy. The flowers, which are greenish and hermaphrodite, are borne in the axils to the number of 2, 3, and 5. All the floral parts are 5 in number. The fruit is a nearly black (first red) berry, about the size of the common pea, and contains rounded-angular (2 or 3) seeds.

History and Description.—This shrub grows in wet situations throughout Europe, Siberian Asia, and the North African coast. It is improperly called *Black alder* in some parts of Europe. The bark is collected from the larger branches and the young tree-trunks in the spring of the year. It should not be used until at least a year old. The *U. S. P.* describes the drug as follows: "Quilled, about 1 Mm. ($\frac{1}{8}$ inch) thick; outer surface grayish-brown, or blackish-brown, with numerous small, whitish, transversely-elongated lenticles; inner surface smooth, pale brownish-yellow; fracture in the outer layer short, of a purplish tint; in the inner layer fibrous and pale yellow; when masticated, coloring the saliva yellow; nearly inodorous; taste sweetish and bitter"—(*U. S. P.*). It yields with cold water a yellow, and with hot water, a brown colored infusion.

Chemical Composition.—This bark contains tannin, purgative extractive matter, an amorphous, non-purgative bitter, and an odorous, volatile principle not yet isolated. The chief constituent, however, is the glucosid *frangulin* (Casselmann), or *rhamnozathin* ($C_{27}H_{40}O_8$, Schwabe, and confirmed by T. E. Thorpe and A. K. Miller, 1892). Carbon disulphide extracts it from the bark, and the principle may be recrystallized from ether or alcohol (see *Proc. Amer. Pharm. Assoc.*, 1892). This body forms silky-lustrous, lemon-yellow crystals. Yellow needles are obtained by sublimation. Frangulin dyes cotton, wool, and silk. It is inodorous and tasteless, soluble in alkaline solutions (with a vivid purple color), but little soluble in ether or cold alcohol, and not at all soluble in water. Upon hydrolysis with dilute acids it yields *emodin* ($C_{15}H_{10}O_6$) (or *tri-oxy-methyl-anthra quinone*) and *rhamnose* (frangula sugar) ($C_6H_{12}O_6$) (*Proc. Amer. Pharm. Assoc.*, 1892, p. 719). Impure frangulin was named *avornin* by Kubly, in 1866. Emodin from this source was identified as such by Liebermann and Waldstein, in 1876, the name *frangulic acid* (*frangulinic acid*) having been previously affixed to it by Faust, in 1869. Both principles (frangulin and emodin) are only to be found in aged bark (*Amer. Jour. Pharm.*, 1888, p. 515).

Action, Medical Uses, and Dosage.—Nausea, colicky pain, and violent emeto-catharsis are the effects produced by fresh frangula bark. When dried, however, it loses some of its acidity, and then acts as a purgative only. Both the alvine and renal discharges are colored dark-yellow by it. Narcotic symptoms have been produced by eating the berries and seeds, the toxic effects having been probably produced by the prussic acid contained in the seeds. The decoction has been administered in *dropsies*, and the same preparation as well as an ointment of the recent bark, has been used for the cure of *itch*. Its chief value, however, is as a laxative and cathartic, being quite popular for these effects with the Germans. It resembles senna and rhubarb in action, according to some, being harsher, but is regarded by Squibb as milder than either. It is a remedy for *chronic constipation*, from 1 to 3 doses of 20 minims of the fluid extract being administered in water in the course of a day. If desirable to evacuate the bowels at once, a fluid drachm may be given at bedtime. An elixir (4 parts of fluid extract to 12 parts of elixir of orange) may be given in from 1 to 2 fluid drachm doses; of the decoction ($\frac{1}{2}$ ounce of bark to $\frac{1}{2}$ pint of water) the dose is a tablespoonful.

FRANKENIA.—YERBA REUMA.

The plant *Frankenia grandifolia*.

Nat. Ord.—Frankeniaceæ.

COMMON NAME: *Yerba reuma*.

Botanical Source and Chemical Composition.—This plant constitutes what is now known throughout the eastern United States as the drug "*Yerba reuma*." This is a small shrubby plant, with a prostrate, much-branched stem, about 6 inches long. It is a native of California, and is found in abundance in sandy localities near the coast. The leaves are opposite, entire, obovate, tapering at the base, and ending in a small, mucronate point. The flowers are sessile, between the forks of the branches, small, and of a bright-pink color. The calyx is tubular, 5-angled, 5-toothed, and hairy externally. The petals are 5, slightly longer than the calyx, and attenuated to slender claws. The stamens are 6 or 7, and about the length of the petals. The pistil consists of a 1-celled, many-seeded

ovary, and 3 slender styles, united for about two-thirds of the way, and stigmatose along the inner surface. This plant is very salty to the taste, having an astringent after-taste. It contains tannin to the amount of about 6 per cent, as seen from an analysis of the plant by Carl Jungk in *Pharmacology of the Newer Materia Medica*, 1892. Yerba reuma was introduced by Dr. J. H. Bundy, of Colusa, Cal., through an article contributed to *New Preparations*, Vol. II, p. 2, 1878. Parke, Davis & Co., under whose auspices that journal was published, brought the fluid extract before the medical profession, and are entitled to the credit of its introduction (see *New Preparations*, 1877-78, and 1879).

Action, Medical Uses, and Dosage.—This plant has been recommended as a mild astringent, having a favorable action upon diseased mucous membranes, and is serviceable in *diarrhœa*, *dysentery*, *vaginal leucorrhœa*, *gonorrhœa*, *gleet*, and *catarrh*. The dose of the fluid extract is from 5 to 25 minims; when diluted with water, it may be applied locally by injection or spray.

FRASERA.—AMERICAN COLUMBO.

The root of *Frasera Carolinensis*, Walter (*Frasera Walteri*, Michaux).

Nat. Ord.—Gentianacæ.

COMMON NAME: *American columbo*.

Botanical Source.—American columbo is an indigenous plant, with a triennial, long, fusiform, horizontal, rugose, and yellow root, and a smooth, erect, solid, cylindrical, or subquadrangular, succulent, dark-purple stem, from 4 to 9 feet in height, 1 or 2 inches in diameter at the base. The leaves are smooth, oblong-lanceolate, acutish, sessile, feather-veined, entire or wavy, subcarnose, from 3 to 12 inches, by 1 to 3, in whorls of 4 to 6, rarely opposite, decreasing in size as they approach the summit. The flowers are tetramerous, 1½ inches in diameter, yellowish-white or greenish-yellow, with brown-purple dots, a large purple pit or gland near the base bordered by a strong and even fringe. They are borne in terminal, compound, pyramidal, leafy, or bracteated, verticillate panicles. The calyx is deeply 4-parted, the segments being acute, and shorter than the oblong, obtusish petals; corolla wheel-shaped. Stamens 4, shorter than the corolla, and alternating with its segments; filaments subulate, anthers large, oblong, versatile, and yellow; ovary oblong, attenuated into a short style; stigma bifid and distinct; capsule or fruit oval, compressed, acuminate with the persistent style, and yellowish; and the seeds few, large, imbricated, elliptical, and wing-margined (L.—G.—W.).

History and Description.—This plant grows west of the Alleghanies, on the borders of lakes and in the rich soils in the middle and southern states, bearing flowers in June and July, which, however, together with the stems, are not developed until the third year, the root-leaves only, in the meantime, being visible. The part used is the root, which should be gathered in October and November of the second year of the plant, or in March and April of its third year; it is hard, fusiform, and wrinkled; as met with in commerce it is in dried, transverse slices, with a brown epidermis slightly tinged with red, yellow cortex, and a spongy, straw-colored center. Its taste is bitter, and its properties are taken up by wine, water, or alcohol of sp. gr. 0.935. The root of this plant has been mistaken for that of calumba, but it may be determined from the latter, which, on account of the starch it contains, strikes a blue color with tincture of iodine, while the American plant undergoes no change of color. Sulphate of iron produces a blackish-green color with an aqueous solution of the American root, but does not affect the foreign root. Tincture of galls gives a dirty-gray precipitate when added to the tincture of calumba. A transverse section of calumba shows a series of concentric circles, with diverging lines, which are absent in the American root. Sliced *frasera* root has been sold as *American gentian*.

Chemical Composition.—American columbo has been investigated by Douglass (*Amer. Jour. Pharm.*, Vol. VI, p. 177), W. R. Higginbotham (*Ibid.*, 1862, p. 23), and F. W. Thomas (*Ibid.*, 1868, p. 309). These authors found it to contain gum, tannic acid, resin, saccharine, fatty and waxy matter, pectic acid, yellow coloring matter, and bitter extractive. Mr. Thomas obtained also some yellow acicular

crystals, and established the absence of albumen, starch, and berberine. In 1873 Mr. G. W. Kennedy showed its chemical relationship to gentian-root by isolating from *Frasera Walteri*, by a somewhat complicated process, two principles found in gentian, viz., the bitter and neutral *gentiopicroin* ($C_{20}H_{30}O_{11}$), soluble in alcohol and water, insoluble in ether, and *gentisic acid* ($C_{12}H_{10}O_6$), yellow crystals of acid reaction, insoluble in water, soluble in alcohol and ether.

John U. Lloyd, in 1880 (*Amer. Jour. Pharm.*, p. 71), published a simple process for the preparation of the yellow crystals, specimens of which were submitted to Mr. Kennedy (1881), and identified as the gentisic acid obtained by him. Additionally, it was found that ferric chloride produced a deep-green coloration with these crystals. Prof. E. L. Patch, reviewing these results experimentally (see *Proc. Amer. Pharm. Assoc.*, 1881, p. 457), concluded that Kennedy's gentisin from *Frasera Walteri*, was not identical with gentisin obtainable from gentian root, but was in all probability a new substance. In 1891 (*Pharm. Rundschau*, p. 143), H. Trimble and J. U. Lloyd resolved the yellow crystals into two substances differing chiefly in their melting points.

Action, Medical Uses, and Dosage.—The recent root of American columbo is said to cause purging and vomiting; but when dried it is a simple tonic, which may be used wherever mild tonics are indicated. Dr. Scudder (*Spec. Med.*, 139), regards it a "stimulant to the circulation," and states that it "will doubtless exert the same influence upon all the vegetative functions." *Obstinate constipation* has been relieved by its persistent use. Dose of the powder, from 20 to 60 grains; of the infusion, from 1 to 4 fluid ounces, 3 or 4 times a day; of specific *frasera*, 5 to 30 drops, well diluted, every 2 to 6 hours.

FRAXINUS.—ASH.

The bark of *Fraxinus sambucifolia*, Lamarck, and *Fraxinus americana*, Linné (*Fraxinus acuminata*, Lamarck; *Fraxinus Eupatoria*, Michaux; *Fraxinus alba*, Marsh), and other species of *Fraxinus*.

Nat. Ord.—Oleaceæ.

COMMON NAMES: I. *Black ash*, *Elder-leaved ash*; II. *White ash*.

Botanical Source and History.—*FRAXINUS SAMBUCIFOLIA* is a tree which attains the height of from 40 to 70 feet. The trunk is covered with a bark of a darker hue than that of the white ash, less deeply furrowed, and from 1 to 2 feet in diameter. The wood is purplish, very tough and elastic, and less durable than the white ash. The leaves are from 9 to 16 inches in length, composed of about 7 leaflets, which are sessile, ovate-lanceolate, serrate, rugose, shining, round-oblique at the base, smooth above, and red-downy on the veins beneath. Calyx and corolla both wanting; buds of a deep-blue color. The samara is elliptical-oblong, and very obtuse at both ends. This species grows in swamps and moist woods in the northern states and Canada, blossoming in May. The young saplings are much employed in making hoops, and the mature trunks for baskets. The leaves when bruised exhale the odor of elder (W.—G.).

FRAXINUS AMERICANA of Linnæus, or the *Fraxinus acuminata* of Lamarck, is a large forest tree, which grows from 50 to 80 feet high; it often rises more than 40 feet without a branch, and then expands into a regular summit of an equal additional height. The trunk is covered with a gray, furrowed, and cracked bark, and the branchlets are smooth and greenish-gray. The leaves are a foot or more in length, opposite, pinnate, consisting of about 7 leaflets, which are petiolate, oblong, shining, acuminate, entire or slightly toothed, and glaucous beneath. The flowers are whitish-green, disposed in loose panicles, the fertile ones with a calyx, the barren ones without. Corolla wanting. The calyx is small and 4-cleft, the buds of a rust color. The samara is spatulate-linear, obtuse, with a long narrowed base. The white ash is chiefly confined to the northern states and Canada, growing in rich woods, and blooming in April and May. Its wood is light, elastic, and durable, furnishing a most excellent timber for carriage-frames, bars, hand-spikes, agricultural implements, etc. (W.—G.).

Chemical Composition.—There are several species of this tree, all of which possess medicinal virtues, probably of a similar character. The bark is the part

used, the properties of which are extracted by water. John M. Bradford, in 1882, found the bark of *Fraxinus americana* to contain, among other substances, an acid and neutral resin, sugar, and gum, and a minute quantity of volatile oil. H. M. Edwards obtained in minute quantity a bitter alkaloid, which he believed to constitute the active principle of the drug. The presence of tannin has also been observed (*Amer. Jour. Pharm.*, 1882, p. 282, and 1883, pp. 117 and 370).

Action, Medical Uses, and Dosage.—Tonic and astringent. An extract of the black ash used as a plaster is very valuable in *salt-rheum* and other *cutaneous diseases*. The infusion may be used internally as a tonic, and for all purposes where a combination of astringency with tonic influence is indicated. The white ash is also cathartic, and has been found beneficial in some cases of *constipation*, and also in *dropsical affections*. It may be used in the form of infusion or in bitters. The bark in white wine, is said to be efficient in curing *ague-cake*, or enlarged spleen. The seeds are said to prevent *obesity*. Dose of specific *fraxinus*, 10 to 60 drops.

Related Species.—*Fraxinus excelsior*, Linné, *Common European ash*. This species is indigenous to Europe, and is cultivated in this country for shade and ornament. A variety is known, *F. excelsior*, var. *pendula*, or *Weeping ash*. The bark of *F. excelsior* had considerable reputation at one time in Europe as a remedy for *intermittents*. The leaves, which are laxative and purgative, according to the quantity taken, have been used successfully in *gouty* and *arthritic rheumatic complaints*. The leaves contain considerable amounts of calcium malate, tannin, some free malic acid, mannit, dextrose, inosit, gum, quercitrin, and a very aromatic volatile oil, of the composition $C_{10}H_{20}O_2$ (Gintl and Reinitzer, *Amer. Jour. Pharm.*, 1883, p. 371). The bark contains a glucosid, bitter and crystalline, known as *fraxin* or *pariin* (see *Æsculus Hippocastanum*). Its formula is $C_{18}H_{18}O_{10}$. Diluted acids split it into *glucose* ($C_6H_{12}O_6$) and *fraxetin* ($C_{10}H_8O_5$). The fruit contains mucilage, tannin, an acrid, resinous body, a bitter substance, and a green oil of a disagreeable odor (Keller). *Fraxinit* (Mouchon's), is a purgative, extract-like body, and is in all probability mannit (Husemann and Hilger, *Pflanzenstoffe*, 1884).

Fraxinus viridis, Michaux; *Green ash*.—Used in Mexico. Leaves and bark tonic; root diuretic.

FUCUS VESICULOSUS.—BLADDER-WRACK.

The marine plant, *Fucus vesiculosus*, Linné.

Nat. Ord.—Fucoideæ.

COMMON NAMES: *Bladder-wrack*, *Sea-wrack*, *Cut-weed*, *Kelp-ware*, *Black-tang*, *Quercus marina*.

ILLUSTRATION: Bentley and Trimen, *Med. Plants*, 304.

Botanical Source.—*Fucus vesiculosus* is a perennial sea-weed. Its root is a hard, flattish disk. The frond or thallus ranges from a few inches to 4 feet in length, and from 2 lines to an inch in width, is flat, furnished with a midrib throughout its length, occasionally twisted in a spiral manner, repeatedly dichotomous, the angles of the dichotomy acute, except when a solitary vesicle happens to be placed there; the sterile branches are obtuse, and often notched at the extremity. The air-vessels vary from the size of a pea to a hazel-nut, and are placed in pairs, situated at irregular intervals in different parts of the frond; sometimes 2 or 3 pairs are arranged next to each other; and they are rarely altogether wanting. The receptacles are terminal, compressed, mostly ovate or elliptical, about $\frac{1}{2}$ inch long, but varying from nearly spherical to linear-lanceolate, and from $\frac{1}{2}$ inch to nearly 2 inches long; they are mostly in pairs, but are sometimes solitary, and occasionally forked. They are filled with a clear, tasteless mucus. The whole frond is proliferous in a remarkable degree in cases of injury, throwing out numerous new shoots from the injured part (L.).

Fig. 115.

History, Description, and Chemical Composition.—*Fucus vesiculosus*, *Sea-wrack*, or *Bladder fucus*, is a common marine plant, growing upon the sea shores of Europe and America. Its substance is rather thick, but flexible and tough, with a dark, olivaceous, glossy-green color, paler at the extremities, and becoming black by drying. Its odor is strong, its taste quite disagreeable, and it contains cellulose, mucilage, mannit, odorous oil, coloring and bitter matters, sodium, and potassium combined with iodine, bromine, and chlorine. The ash of this plant amounts to about 3 per cent; of this ash, iodine con-

stitutes about 0.7 per cent. On account of the iodine contained in its charcoal, known as *Vegetable ethiops* (*Ethiops vegetabilis*), it has been found beneficial in scrofulous enlargements of the glands; the plant being incinerated in a covered crucible, and the charcoal given in doses of from 10 grains to 2 drachms. When burned in the open air it yields *kelp*; it is used as a manure in some places, and is also fed to cattle during the winter. Probably other species of *Fucus* have analogous virtues.

Action, Medical Uses, and Dosage.—M. Duchesne Duparc recommended an infusion of this plant or the extract in pill form for the purpose of lessening *obesity*. It requires to be used 3 or 4 weeks before this effect will be observed, which is preceded with an augmented secretion of urine, presenting a black pellicle upon its surface upon standing for a short time. Others have confirmed this statement regarding it. Later experiments by numerous good observers do not seem to indicate that sea-wrack has any power as a fat-reducer, but that the reduction which takes place in some instances is undoubtedly due to the dietary measures which are a part of the treatment. It is thought, however, to have some power of toning muscular fiber, and has been suggested to prevent *fatty degeneration of the heart*. It influences the kidneys, lessening renal congestion and resultant irritation, and is therefore of service in *acute desquamative nephritis*; it also relieves *cystic irritation* and *chronic inflammation of the bladder*. Take of specific fucus from 5 to 20 drops, every 3 hours. It was at one time recommended to remove *deposits* and *tissue hypertrophies*, as well as *benign* and *malignant tumors*. It is a remedy which deserves a careful investigation, especially in regard to its influence over waste and nutrition. It acts quite powerfully upon the glandular system as an alterative, and is recommended for *menstrual derangements* with weak, flabby uterine walls. Dose, of specific fucus, 5 to 30 drops.

Related Species.—The following plants are thought to possess similar properties, the first mentioned having been allowed by the *French Codex* as a substitute for bladder-wrack: *Fucus siliculosus*, Linné (*Cystoseira siliculosa*, Agardh; *Halidrys siliculosa*, Lyngbye), *Fucus serratus*, Linné, *Fucus natans*, Linné (*Sargassum bacciferrum*, Agardh), *Fucus nodosus*, Linné (*Fucodium nodosum*, Agardh) *Fucus digitatus* contains much more iodine (7 or 8 times as much) than bladder-wrack.

FUMARIA.—FUMITORY.

The plant *Fumaria officinalis* Linné.

Nat. Ord.—Fumariaceæ.

COMMON NAME: *Fumitory*.

ILLUSTRATION: Johnson's *Med. Bot. of N. A.*, Fig. 104.

Botanical Source.—This is an annual glaucous plant, with a sub-erect, much-branched, spreading, leafy, angular stem, growing from 10 to 15 inches high. The leaves are mostly alternate, bipinnate, or tripinnate; the leaflets are wedge-shaped, cut into flat, lanceolate segments. The flowers are small, flesh-colored, tipped with crimson, nodding, the pedicles becoming erect in fruit. The racemes are opposite to the leaves, stalked, erect, many-flowered, and rather lax. The bracts are lanceolate, acute, and not half the length of the pedicles, especially when in fruit. Petals 4, unequal, one of them with a short, rounded spur at the base. The calyx is colored, toothed, and deciduous. The fruit or nut is ovoid or globose, indehiscent, emarginate, 1-seeded, and valveless, and the seed crestless (W.—G.).

History and Description.—This plant is found growing in cultivated soils in Europe and this country, bearing red flowers in June and July. The leaves, which are generally used, have no odor, but a bitterish taste, and, when fresh, furnish a large quantity of an aqueous, bitter, and inodorous juice, which possesses their therapeutical properties, and which is soluble in water, wine, or alcohol.

Chemical Composition.—The most prominent constituents of fumitory are an alkaloid *fumarine*, *fumaric acid*, and considerable amounts of inorganic matter, especially potassium salts. Upon incineration, *Fumaria officinalis* leaves about 8 per cent of potassium carbonate (Husemann and Hilger, *Pflanzenstoffe*, 1884). *Fumarine* was probably first obtained by Peschier, in 1829, and later investigated by Hannon (1852), Preuss (1866), and others. It forms colorless, monoclinic prisms, bitter in solution, soluble in alcohol, amyl alcohol, chloroform, benzene,

and carbon disulphide, little soluble in water, insoluble in ether. It is related to the corydaline of Adermann (see *Amer. Jour. Pharm.*, 1890, p. 34). According to Reichwald (*Jahresb. der Pharm.*, 1889, p. 406), it has the formula $C_{10}H_{10}O_4$. More recently Battandier observed its occurrence in a papaveraceous *Fumaria corniculatum*, var. *phoeniceum*, and a variety of other plants (*Ibid.*, 1891). Fumaric acid ($C_4H_4[COOH]_2 = C_4H_2O_4$), occurs in a number of different plants, in Iceland moss, and was first isolated from fumitory, in 1833, by Berzelius. Fumaric acid is obtained by heating malic acid ($C_4H_4O_5$) with water and with sulphuric acid, to $180^\circ C.$ ($356^\circ F.$), whereby 1 molecule of water is evolved. It occurs in colorless prisms or stellate scales, is somewhat soluble in cold water, more soluble in hot water, to which it imparts an acid reaction; is also soluble in alcohol and ether, and forms salts with bases mostly soluble in water, but the acids are insoluble in absolute alcohol (Husemann and Hilger).

Action, Medical Uses, and Dosage.—It is a weak tonic, very much used in *cutaneous diseases*, in *jaundice*, *obstructions of the abdominal viscera*, and in *cases of debility of the digestive organs* (E. and V.). It is also slightly cathartic and aperient. Dose of the infusion, a wineglassful every 2 or 3 hours. The expressed juice, $\frac{1}{2}$ wineglassful, 2 or 3 times a day. Two ounces of the flowers infused in 8 pints of Madeira wine, and taken twice a day in doses of 2 to 4 fluid ounces, will strengthen the stomach and improve the appetite.
